Here we report the crystal structure of a cytosolic isoform of CK derived from bovine photoreceptor cells. The structure of bovine retinal brain type creatine kinase (brB-CK) homo dimer has been solved initially to 2.7Å and then further to a resolution of 2.3Å with one monomer in the asymmetric unit. The brB-CK monomer consists of a small helical domain consisting of 6 helices and a large domain comprising of an 8 stranded anti-parallel § sheet surrounded by 7 helices. The proposed nucleotide and creatine binding sites are located in a cleft between the two domains. The overall fold of brB-CK is similar to that of Mi_b-CK, a CK isoform located in the mitochondrial inter membrane space. Further to this, through comparative studies of the transition state complex of horseshoe crab arginine kinase, a close homologue of creatine kinase, those regions of brB-CK involved in substrate binding and catalysis have been identified.

P06.04.025 HISTIDINE DECARBOXLASE COOPERATIVITY IS CONTROLLED BY A pH DEPENDENT α-HELIX CONFORMATIONAL CHANGE. Jon D. Robertus, Arthur F. Monzingo, Elisabeth Schelp, Scott Worley and Stephen Ernst, Institute of Cellular and Molecular Biology, Department of Chemistry and Biochemistry, University of Texas, Austin TX, 78712.

Histidine decarboxylase (HDC) from *Lactobacillus* catalyzes the conversion of histidine to histamine and CO_2. A histidine/histamine shuttle system generates energy for the cell and also neutralizes the cytoplasmic pH in the lactic acid producing bacteria. HDC is activated by low pH and inhibited at neutral pH; its cooperative kinetics suggests interconversion of the

trimeric enzyme between a high Km T state and a low Km R state. The putative R state of HDC, pH 4.5, was solved by others nearly 15 years ago. This molecule revealed that active sites are formed at the interfaces of HDC trimers. It also revealed a close interaction of aspartate side chains, including D53, across the intermolecular interface. This interaction may be part of a trap that binds protons at low pH, stabilizing the R state; at high pH the protons are pulled out and charge repulsion triggers a structural change. We have now solved the pH 8 structure of HDC at 3 Å resolution to analyze the T state. We also created a site directed mutant involving D53; this mutant has T state kinetics and suggests it is also in the T quaternary structure. Both T form crystals reveal that an active site helix, anchored by D53 is disrupted and that the histidine binding site is altered by the conformational change. We also solved the structure of the mutant HDC with a covalent inhibitor, HME, in the active site. This substrate analog forces the active site into the R state reforming the active site α-helix. This shows that substrate as well as protons, can stabilize the R state.

P06.04.026 CRYSTRAL STRUCTURE ANALYSES OF THE ENZYMES INVOLVED IN THE DEGRADATION OF POLYCHLORINATED BIPHENYLS. T. Senda, K. Sugimoto, E. Masai, M. Fukuda and Y. Mitsui, Department of BioEngineering, Nagaoka University of Technology, Nagaoka, Niigata 940-2188, JAPAN.

Polychlorinated biphenyls (PCBs) are widely distributed, toxic and carcinogenic, environmental pollutants. PCBs are significantly recalcitrant to biodegradation due to their chemical stability. The total amount of PCBs released into the biosphere is *ca.* 750,000 tons. PCBs have accumulated and concentrated in the tissues of fish, birds and other wildlife. The accumulation of PCBs has even been observed in human bodies. A few of the toxic symptoms caused by PCBs involve headache, pain of joints and hypertension. Since 1973, a number of microorganisms that could degrade PCBs have been isolated and characterized. In addition some field attempts at PCB biodegradation have been carried out.

To date the major biodegradation pathway of PCBs has been established. Thus, four specific enzymes, biphenyl dioxygenase (BphA), dihydrodiol dehydrogenase (BphB), 2,3-dihydroxybiphenyl dioxygenase (BphC) and 2-hydroxyl-6-oxo-6-phenylhexa-2,4-dienoic acid hydrolase (BphD) are sequentially involved in the oxidative degradation of PCBs into chlorobenzoates and 2-hydroxypenta-2,4-dienoate. Three-dimensional structural information of these enzymes is required for a rational improvement of the degradation pathway to utilize these enzymes for bioremediation. Thus we have carried out the crystallographic analyses of these enzymes derived from microbes that can degrade PCBs and related aromatic compounds. To date we have determined the crystal structures of an electron transfer component of BphA (BphA4), BphB, BphC, and BphD. In addition, analyses of structure-function relationships have been carried out using a variety of mutant proteins. These structure-based studies on the whole degradation pathway will provide a novel insight into the function and mechanism of the degradation pathway of PCBs, which must be useful for the rational improvement of the degradation pathway.

P06.04.027 CRYSTAL STRUCTURE AND PROPOSED MECHANISM FOR METHIONINE γ-LYASE FROM *TRICHOMONAS VAGINALIS*. G. Goodall, Protein Crystallography, Dept. of Chemistry, University of Glasgow, Glasgow. G12 8QQ, UK. G.H. Coombs, Biochemical Parasitology, Division of Infection and Immunity, University of Glasgow, Glasgow, G12 8QQ, UK; A. Lapthorn, Protein Crystallography, Dept. of Chemistry, University of Glasgow, Glasgow. G12 8QQ, UK.

Methionine γ-lyase (MGL) (E.C. 4.4.1.11) is a pyridoxal 5'-phosphate (PLP) dependent enzyme able to catalyse αγ- and αβ-elimination as well as γ and β replacement reactions on the sulphur containing amino acids L-methionine and L-cysteine and their analogues. The enzyme has only been detected in anaerobic micro-organisms at this time and is thought to be absent from yeast and mammals where multiple PLP dependent enzymes carry out similar reactions. The human parasite *T. vaginalis* is the causative agent of trichomoniasis the most prevalent non-viral sexually transmitted disease in the world. The parasite has an exceptionally high level of activity of MGL and two genes have recently been cloned from the parasite which encode for isoforms of the enzyme [1]. The exact role of the enzyme for the parasite is still under investigation but there is evidence that the enzyme is responsible for the activation of pro-drugs *in vivo*.

We have overexpressed and purified both forms of the enzyme and successfully crystallised the first of these, MGL1. The crystals are trigonal, space group $P3_112$ with a=b=88.53Åand c=217.85Å. The crystals were shown to diffract to 1.6Å at Daresbury SRS station 9.5 where a complete 2.2Å dataset was collected. The structure was solved by molecular replacement using AMoRe [2]. The structure of native and an inhibitor complex of MGL1 have now been obtained and with data from site directed mutagenesis experiments we are able to propose a model for the enzyme mechanism. Studies are now under way to design specific inhibitors of the enzyme for possible use *in vivo*.

P06.04.028 X-RAY CRYSTAL STRUCTURE AT 2.4 Å RESOLUTION OF HUMAN GLUCOSAMINE-6-FOSFATE DEAMINASE (GLCN6PDH). R. Arreola, [1], L. I. Álvarez-Añorve [2], L. Morante, E. Hojales [1], [1] Departamento de Reconocimento Molecular y Bioestructura, Instituto de Biotecnología, Universidad Nacional Autónoma de México, Cuernavaca, Morelos, México, [2] Departamento de Bioquímica, Facultad de Medicina,Universidad Nacional Autónoma de México, México city, D.F.México.

GlcN6PDH catalyses the transformation of D-Glucosamine-6-fosfate to fructose-6-fosfate and ammonia (E.C.5.3.1.10) (Calcagno,M.et.al.personal communication). The enzyme is hexameric whith identical sub-units 289 residues each. Biochemical function is conserved with regard to E.coli deaminase (Altamirano, M.et.al.1995) (primary sequence has 52% of identity). Desaminase enzyme has wide distribution in evolutive scale (eubacteria, protoctista, invertebrates, insects and mammals). The enzyme is present in humans and hamsters, in many cells types, which shares high energy requirements. In particular it has been found in spermatozoids, in isolated fractions that produce calcium oscillations in ovocite cells (Parrinton,P.et.al.1996). The structure of GlcN6PDH has been determinated and refined to 2.4 Å resolution, using molecular replacement. Spatial group is p212121 with cell parameters 113.38Å, 115.93Å, 181.43Å, 90°,90°,90°. The structure is complexed whit allosteric activator N-acetyl-glucosamine-6-phosphate and the competitive inhibitor 2-deoxy-2-amino-glucitol- 6-phosphate. Comparative superposition of E. coli and human monomers showed an r.m.s. 0.452. The active site residues are notably conserved as compared with the E.coli conformations in state R. An exception is 43 residue (change from Gly to Ser in GlcN6PDH) that produce a new hydrogen bond with Arg 172 side chain. The C-terminal helix 8 of GlcN6PDH is very different to E. coli GlcN6PD probably related with experimentally observed different allosteric properties. Helix 8 forms a cavity surrounding more closely the allosteric site building a hydrophobic pocket that lodge the N-Acetyl group. A new hydrogen bond joints the activator with His 262 confirming the biochemical data about high

affinity of allosteric activator. This project was supported by DGAPA-UNAM IN23598. R.A. received a grant from CONACyT. We acknowledge Sonia Rojas for technical support for crystallisation.

P06.04.029 STRUCTURAL ANALYSIS OF STREPTOMYCES OLIVACEOVIRIDIS β-XYLANASE BY MOLECULAR REPLACEMENT METHOD. Z. Fujimoto and H. Mizuno, National Institute of Agrobiological Resources, Tsukuba, Japan, and A. Kuno, S. Yoshida and I. Kusakabe, University of Tsukuba, Tsukuba, Japan, and H. Kobayashi, National Food Research Institute, Tsukuba, Japan

Xylanases (EC 3.2.1.8) or endo-1,4-β-D-xylanases hydrolyze the β-1,4-glycosidic bonds within the xylan backbone and belong to either family F/10 or G/11, on the basis of the amino acid sequence similarities of their catalytic domains. Family F/10 xylanase consists of catalytic domain comprising a $(\beta/\alpha)_8$-barrel, C-terminal substrate-binding domain, and a linker region connecting two domains. By now, five family F/10 xylanase structures have been determined, however, they are only of their catalytic domains. Recently we succeeded in crystallizaion of intact *Streptomyces olivaceoviridis* E-86 β-xylanase (FXYN). To understand the substrate-recognition or binding mechanism of this enzyme, we have analyzed the structure of FXYN.

The crystals belong to orthorhombic space group $P2_12_12_1$, with cell dimensions of a =79.6Å, b =95.2Å, and c=140.3Å, including two molecules per asymmetric unit. Diffraction experiment on the native crystal was carried out at the Photon Factory in Tsukuba to 1.9Å resolution, resulting a completeness of 94.2% and an R_{merge} of 0.055.

Structural analysis was performed firstly by the molecular replacement method. As a search model, a structural model of the catalytic-domain of FXYN (residues 1-300) was build with the program MODELER in QUANTA program package using two catalytic-domain structures; xylanases from *Streptomyces lividans* (1xas) and *Cellulomonas fimi* (2exo). This model was subjected to molecular replacement using the 8-3.5 Å resolution data with the program AMoRe in CCP4 suite, finally resulting the correlation of 52.1 and *R*-value of 46.6. The quality of the electron density map was sufficient to identify amino acids in the catalytic domain. The structure was refined with the program XPLOR to 2.5Å resolution, and resulted in a *R*-factor of 32.4. The resultant Fo-Fc map gave electron density corresponding to the substrate-binding domains, and the 3Fo-2Fc map allowed us to identify some Trp residues. Amino acid residues were added into the model one by one on the renewed map. This process was repeated, and finally all of 123 residues in this domain were assigned. Subsequent refinements were carried out to a resolution of 1.9 Å and R/R_{free}-factors were lowered to 21.0/25.3.

P06.04.030 STRUCTURE OF D-GLYCERALDEHYDE-3-PHOSPHATE DEHYDROGENASE FROM PALINURUS VERSICOLOR Shi-ying Song, Yue-quan Shen, Zheng-jiong Lin, National Laboratory of Biomacromolecules, Institute of Biophysics, Academia Sinica, Beijing 100101, China

D-Glyceraldehyde-3-phosphate dehydrogenase (GAPDH) is an important enzyme in both glycolysis and glyconeogenesis. A series of crystal structures of GAPDH from Palinurus versicolor (PV), South China sea Lobster, were determined. The structure of PV native enzyme has been published (Song, et al. 1998). The isomorphous structures of carboxymethylaed GAPDH and apo-GAPDH have also been refined at high resolution to a reasonable stereochemistry and final R-factor of 17.4% (1.88Å) and 17.1% (2Å) respectively. The whole tetramer of apo-GAPDH exhibits good 222 molecular symmetry. The conformational change induced by coenzyme binding is similar to but less than that found in Bacillus stearothermophilus GAPDH. The differences between these two species during apo-holo transition are attributed to the sequence differences. In the structure of active-site carboxymethylated GAPDH connected to Cys149 is stabilized by a hydrogen bond between its OZ1 and Cys149N, the modification of Cys149 induced conformational changes in the active-site, in particular, the site of sulphate ion Pi and segment 208-218 nearby. It is proposed that the carboxymethyl group takes the place of the acyl group of the reaction intermediate and the catalytic mechanism of this enzyme is discussed in the light of a comparison of the structures of the native and the carboxymethylaed GAPDH.

P06.04.031 CRYSTAL STRUCTURE OF THE *VMA1*-DERIVED ENDONUCLEASE BEARING AN N-TERMINAL PROPEPTIDE. R. Mizutani and Y. Satow, Graduate School of Pharmaceutical Sciences, Y. Ohya, Graduate School of Science, University of Tokyo, Tokyo 113-0033, Japan, M. Kawasaki, The Tokyo Metropolitan Institute of Medical Science, Tokyo 113-8613, Japan, Y. Anraku, Teikyo University of Science and Technology, Yamanashi 409-0193, Japan.

The 120-kDa nascent product the *VMA1* gene of *Saccharomyces cerevisiae* auto-catalytically excises out the 50-kDa endonuclease VDE (*VMA1*-derived endonuclease) and splices the two external polypeptides to form the 70-kDa subunit of the vacuolar H^+-ATPase. Only six proximal and four distal amino acids are required for auto-catalytic processing of folding-dependent *in vitro* protein splicing. Another recombinant named XA-VDE is similar in construction but is a splicing-negative polypeptide in which cysteines 284 and 738 at the splicing junctions are replaced with alanines. In order to obtain structural insight of the protein splicing reaction, we have carried out a 2.0 Å resolution crystallographic study on the XA-VDE protein.

The XA-VDE protein was crystallized using polyethylene glycol as a precipitant. The structure was determined by the molecular replacement method using the mature VDE structure as a search model, and has been refined to an *R* factor of 0.204. Gly 282 and Val 283 in the N-terminal region are clearly observed in electron densities, and are located in the vicinity of the side chain of His 362 which is requisite for the splicing reaction. As the C-terminal region from Ala 738 to Arg 741 has no convincing densities, the XA-VDE protein was subjected to high resolution mass spectrometry. The observed mass of 51,569 Da is in close agreement with a predicted mass for a polypeptide lacking the C-terminal region (51,577 Da). The structures of the XA-VDE and mature VDE proteins give an rms positional difference of 0.5 Å for alpha carbons, indicating the external peptide has little effect on the overall XA-VDE structure. We propose that the mechanism of the cleavage at the C-terminal region involves succinimide formation at the downstream splicing junction, which results in the cleavage as in the later step in protein splicing reaction.

P06.04.032 K187T MUTANT CYCLOPHILIN B FROM *E. COLI* COMPLEXED WITH TETRAPEPTIDE. M. Konno, Y. Sano, Y. Kawaguchi, and Y. Yamagishi, Department of Chemistry, Ochanomizu University, Otsuka, Bunkyo-ku, Tokyo 112-8610 Japan and S. Fushinobu and H. Matuzawa, Department of Biotechnology, University of Tokyo, 1-1-1 Yayoi, Bunkyo-ku, Toyko 113-8657 Japan.

Cyclophilins are ubiquitous and abundant proteins for which a natural role has not been found. Cyclophilin A (CyPA) is present in the cytosol and cyclophilin B (CyPB) binds to the membrane with the signal sequence in N-terminal. Crystals of CyPB of the wild type from *E. coli* never were obtained. In

consideration of two conditions 1) mutants decrease no PPIase activity 2) residues hydrated to disturb interactions between molecules should be replaced by more hydrophobic residues, compared with *E. coli* CyPA, two kinds of mutants of K187T and H110F were prepared. Crystals of these mutants have been grown. Crystals of the complex of K187T mutant protein and tetrapeptide (Acetyl-Ala-Ala-Pro-Ala-7-amido-4-methyl-cumarine) belong to *trigonal,* space group *P*32, *a*=*b*=78.96 Å, *c*=56.17 Å, *Z*=6. Two protein molecules and one tetrapeptide are included in asymmeric unit. The intensity data were collected at synchrotron radiation in the Photon Factory KEK Japan. The structure has been resolved by molecular replacement methods using the structure of *E. coli* CyPA as a search model. The refinement gave *R*=0.223 at 2.0 Å resolution.

Two molecules I and II in *E. coli* CyPB have the β-barrel structure consisting eight-antiparallel β-strands with two α-helices at the top and the bottom, as *E. coli* CyPA, yeast CyPA, human CyPA and CyPB have. The hydrophobic cleft is formed by side chains of Phe77, Met78, Phe128, Phe136, Lue137 and Tyr146 over upper β-sheet. A tetrapeptide including *cis*-proline is inserted into this cleft of one molecule II. The cumarine ring lies parallel into the benzene ring of Phe136. Another molecule I has no tetrapeptide. The side chains of Lue184, Ser185, Thr187 on β8 and Lue32, Thr34 on β1 of molecule I form hydrophobic interactions with those of the adjacent molecule II.

P06.04.033 THE X-RAY CRYSTAL STRUCTURE OF A TN5 TRANSPOSASE-RELATED PROTEIN DETERMINED TO 2.9 Å RESOLUTION. D.R. Davies, I. Rayment [1], L.A.M. Braam, W.S. Reznikoff [2], [1] Institute for Enzyme Research and Department of Biochemistry, University of Wisconsin, Madison, Wisconsin, USA, [2] Department of Biochemistry, University of Wisconsin, Madison, Wisconsin, USA.

We report the three-dimensional structure of the Tn5 transposase inhibitor protein, a slightly truncated version of the full length transposase enzyme. The inhibitor protein prevents transposition through a self-regulatory mechanism unique to transposon Tn5. The inhibitor protein differs from the full length transposase only by the absence of the first 55 N-terminal amino acid residues. It is 421 amino acid residues in size, and contains the active site of the transposase and a C-terminal domain involved in protein-protein interactions. A portion of the protein fold of the catalytic core domain is similar to the folds of HIV-1 integrase, Avian Sarcoma Virus integrase, and bacteriophage Mu transposase. The Tn5 inhibitor contains an insertion in this conserved catalytic core that extends the central beta sheet from five to nine strands. All three of the conserved acidic residues that make up the "DDE" motif of the active site are visible in the structure. An arginine residue that is strictly conserved among the IS4 family of bacterial transposases is present at the center of the active site, suggesting a catalytic motif of "DDRE." A novel C-terminal domain forms a dimer interface across a crystallographic twofold axis. Although this dimer represents the structure of the inhibited complex it provides insight into the structure of the synaptic complex.

P06.04.034 CRYSTAL STRUCTURE OF A FAMILY G XYLANASE FROM *ASPERGILLUS NIGER* AT 2.4 Å RESOLUTION. U. Krengel, Center for Structural Biology, Chalmers University of Technology and Göteborg University, Department of Biochemistry and Biophysics, P.O. Box 462, 403 50 Göteborg, Sweden, and B. W. Dijkstra, BIOSON Research Institute, University of Groningen, Department of Biophysical Chemistry, Nijenborgh 4, 9747 AG Groningen, The Netherlands.

Xylanases belong to the glucanase enzyme family and are characterized by their ability to break down various xylans to produce short-chain xylo-oligosaccharides. Since the enzyme plays a crucial role in the breakdown of plant cell walls and cell wall constituents, it is of major importance for a large number of industrial applications ranging from the clearing of fruit juices to benefits in paper industry. In food industry, xylanase-supplemented food plays an important role in effective feeding and reduction of animal excrements. Especially fungal xylanases, which generally have lower pH-optima, are ideally suited to release important nutrients in such acidic environments as the animal stomach.

One of the xylanases, the endo-1,4-β-xylanase I (EC 3.2.1.8) from *Aspergillus niger*, is produced at industrial scale by the company Gist-Brocades in Delft (The Netherlands). It has a pH-optimum of 3.5, consists of 184 amino acids and has a molecular mass of 20 kD. Various crystal forms of the enzyme could be obtained with the hanging drop method, using inorganic salts as precipitants. The X-ray structure of the *A. niger* xylanase has been solved by molecular replacement, using the coordinates of a xylanase from *Trichoderma harzianum* (D. Rose, personal communication) as a model. Like all the other members of the family G xylanases of which the structure has been solved to date, the *A. niger* xylanase has an extensive β-sheet structure and contains only one α-helix at the outside of the molecule. Two mostly antiparallel β-sheets are stacked against each other and are twisted around a deep, long cleft which is lined with many aromatic amino acids and which is big enough to accommodate several xylose residues. The two conserved glutamic acid residues Glu-79 and Glu-170, which habe been shown to be involved in catalysis in other members of the xylanase G family, are reaching into this cleft from opposite sides. A mechanism is proposed which explains the unusually low pH-optimum of this xylanase.

P06.04.035 STRUCTURE OF THE FLAVOENZYMES: MORPHINONE REDUCTASE AND PETN REDUCTASE Peter C.E. Moody, Daniel H Craig, Terez M Barna and Nigel S Scrutton, Department of Biochemistry, University of Leicester, Leicester LE1 7RH, U.K. & Neil C Bruce Institute of Biotechnology, University of Cambridge, Cambridge CB2 1QT UK

We have determined the structures of both morphinone reductase (to 2.0Å) and pentaerythritol tetranitrate (PETN) reductase (to 1.5Å). These enzymes are members of the Old Yellow Enzyme family of flavoenzymes and catalyse the reduction of morphinone to hydromorphone using NADH and the reduction of PETN, TNT or glycerol trinitrate using NADPH respectively. They have enormous potential in the production of analgesics and the bioremediation of explosive contaminated land. The structures will be presented in complex with various substrates and inhibitors, and compared to OYE. The nature of the reactions catalysed by these enzymes and their specificities will be discussed in the context of these similar structures.

P06.04.036 CRYSTAL STRUCTURE OF A NIFS-LIKE PROTEIN FROM *ESCHERICHIA COLI*. T. Fujii, M. Maeda, H. Mihara, T. Kurihara, N. Esaki and Y. Hata, Institute for Chemical Research, Kyoto University, Uji, Kyoto 611-0011, Japan.

CsdB, the *csdB* gene product from *Escherichia coli*, is a pyridoxal 5'-phosphate(PLP)-dependent protein, which decomposes L selenocysteine, L-cysteine sulfinic acid and L-cysteine, into selenium, sulfur dioxide and sulfur, respectively, and L-alanine. This enzyme shares 23% sequence identity with the NifS protein, that catalyzes the decomposition of L cysteine and functions in the nitrogen fixation system of *Azotobacter vinelandii* by supplying sulfur to stabilize or repair the iron-sulfur cluster of the nitrogenase component protein. In order to clarify structure-function relationships of a family of NIFS-like proteins,

we have determined the three-dimensional structure of CsdB by X-ray crystallographic analysis.

The crystals of CsdB were grown by a hanging drop vapor diffusion method using sodium acetate as a precipitant. They belong to space group $P4_32_12$ with unit cell dimensions of $a = b = 128.1$ Å and $c = 137.0$ Å. Two heavy-atom derivatives were prepared using phenyl mercury acetate and potassium tetracyanoplatinate. Diffraction data for the native and two derivative crystals were collected on an R-AXIS IIc imaging plate detector system. The structure was solved by the multiple isomorphous replacement method with anomalous scattering and density modification techniques. The structure was refined to an *R*-factor of 0.187 at 2.8 Å resolution.

CsdB is a homo-dimer with the subunit composed of 406 amino-acid residues and one PLP. The overall fold of the subunit is similar to those of the α-family of PLP-dependent enzymes, represented by an aspartic acid aminotransferase. The subunit consists of three parts: the large domain of an α/β fold containing a seven-stranded β-sheet flanked by helices, the small domain containing a four-stranded β-sheet with three α-helices, and the N-terminal segment. However, CsdB has several structural features which are different from those of other families of enzymes. A β-hairpin loop protruding from one subunit of the dimer interacts with an α-helix in the lobe extending from the small domain to the large domain of the other subunit. These two portions of β-hairpin loop and the lobe form one side of a limb of an active site in the enzyme. The most striking structural feature of CsdB is that the side chain of Cys364, a putative catalytic residue, which lies on the extended lobe, is close enough to interact with γ-atom of the substrate.

P06.04.037 X-RAY CRYSTALLOGRAPHIC ANALYSIS OF THE CATALYTIC MECHANISM OF L-2-HALOACID DEHALOGENASE. Y. Hata, Y.-F. Li, T. Fujii, T. Kurihara and N. Esaki, Institute for Chemical Research, Kyoto University, Kyoto 611-0011, Japan.

L-2-Haloacid dehalogenase from Pseudomonas sp. YL is a dimeric enzyme that catalyzes the hydrolytic dehalogenation of L-2-haloalkanoic acid to yield the corresponding D-2-hydroxyalkanoic acid. The enzyme subunit consists of 232 amino acid residues with molecular weight of 26,179. Our mass-spectroscopic studies revealed that the enzymatic reaction proceeds by the two-step mechanism via ester intermediate. In order to elucidate the catalytic mechanism of the enzyme based on structural changes in process of the reaction, crystal structures of the enzyme have been determined in the forms of the native, the ester intermediate and the enzyme-product complex. The subunit is composed of two structurally distinct domains; the core domain for catalysis and the subdomain for dimerization. The core domain has an a/b-structure formed by a six-stranded parallel b-sheet flanked with five a-helices, and the subdomain has a four-helix-bundle structure. The catalytically important rsidues of Asp10, Thr14, Arg41, Ser118, Lys151, Tyr157, Asn177 and Asp180 are located in the active site cleft between both domains. The negatively charged substrate is probably taken into the enzyme by the electrostatic interaction with Arg41 at the active site entrance. In the active site, the carboxyl group of the substrate is fixed by the hydrogen bonds to the side chain of Ser118, and the alkyl group of the substrate is stabilized in the hydrophobic pocket, which is primarily composed of Lys151, Asn177 and Trp179 and may play an important role in determining the stereospecificity of the enzyme. The halogen atom is abstracted from the substrate C2 atom by the guanido group of Arg41, and concurrently Asp10 in the opposite side makes an nucleophilic attack on the C2 atom to form the ester intermediate. In this process, the Walden's inversion occurs at the C2 atom of the substrate, and consequently the substrate moiety adopts a D-configuration. In the intermediate formation, the regions of Asp10-Ser20 and Leu117-Arg135 move into the active site, the side chain of Asp10 rotates largely, and a new water molecule occurs in the vicinities of Asp10, Ser175, Asn177 and Asp180. The water molecule is probably activated by the deprotonated carboxyle group of Asp180 and serves as the nucleophile for hydrolysis of the ester intermediate. After the hydrolysis, the carboxyl group of Asp10 rotaes so as to be hydrogen-bonded to that of Asp180. Finally the product is released, and the enzyme is restored to the original state.

P06.04.038 STRUCTURAL STUDY OF CobA: AN ADENOSYL TRANSFERASE INVOLVED IN THE VITAMIN B_{12} BIOSYNTHETIC PATHWAY. Cary B. Bauer[1], Maris Fonseca[2], Jorge Escalante-Semerena[2], and Ivan Rayment[1], Departments of Biochemistry[1] and Bacteriology[2], University of Wisconsin, Madison, WI 53705, USA.

Vitamin B_{12}, an essential human nutrient, represents one of the most complex organic cofactors to be employed in living systems. The successful three-dimensional structural determination of a coenzyme form of this vitamin, namely 5'-deoxyadenosylcobalamin, represented a landmark in X-ray crystallography. The biosynthesis of this complex molecule requires numerous steps including an adenosyl transfer from ATP to the cobalt atom of cobyric acid. The enzyme responsible for this step in *S. typhimurium* is CobA. This 196 amino acid protein is capable of binding a variety of cobalamin compounds which are substituted at the upper ligand including cyano-, hydroxy-, and the previously mentioned adenosylcobalamin. We have very recently determined the crystal structure of CobA in the absence of any substrate. This form of CobA crystallizes in $P6_522$ with unit cell dimensions of a=b=49.38, c=250.10 and was solved utilizing MAD phasing on data collected on a selenomethionine substituted protein. The structure reveals a molecular dimer which contains a mixed helix/sheet topology. We currently have obtained diffraction quality crystals in which CobA was co-crystallized in the presence of both hydroxycobalamin and adenosylcobalamin. We expect to be able to present the structures of these substrate bound forms in addition to the apo form. The combination of these structural results will hopefully shed light on the mechanism involved in this step of the synthetic pathway.

P06.04.039 OPEN STRUCTURE OF PIG MUSCLE 3-PHOSPHOGLYCERATE KINASE (PGK) WITH BOUND MG-ADP AND 3-PHOSPHOGLYCERATE (3PG). M. Vs Kazinczy, & A. N. Szilgyi, Institute of Enzymology, BRC, Hung. Acad. Sci., Budapest, Hungary & M. Ghosh, Laboratory of Molecular Biophysics, Department of Biochemistry, University of Oxford, UK

The mechanism of relative domain movements and its role in the catalysed phospho-transfer is investigated on PGK, a typical two-domain kinase, which catalyses the phospho-transfer from 1,3-bisphosphoglycerate to MgADP to form 3-phosphoglycerate and MgATP. Crystals of pig muscle PGK were grown in the presence of MgADP and 3-PG in 2.5 M phosphate, pH 8.0, i.e. under the conditions which has resulted in crystals of the closed, catalytically competent conformation of Trypanosoma brucei PGK (1). The crystal structure of the ternary complex has been determined at 1.8Å resolution with R=20.8% and Rfree=24.1%. This structure interestingly shows that the enzyme is in an open conformation, in contrast to that of T. brucei PGK, despite the fact the crystals were grown under similar conditions.

The mode of interaction of the phosphates of the nucleotide with PGK is remarkably different in the two structures. In the pig muscle PGK structure, the β-phosphate of MgADP does not interact with helix 13 which is a key element in the interdomain region. Systematic comparison of all the available PGK ternary complex structures with different domain positions has revealed

the importance of this contact with the nucleotide, and delineated at atomic level, a very probable mechanism of the domain closure. In addition to the previously observed C- and N-hinge points, the importance of the interdomain helices 13 and 14 as well as the connecting β-sheet L is now demonstrated and a third hinge point is proposed.

P06.04.040 STRUCT ANALYSIS OF CALF SPLEEN PURINE NUCLEOSIDE PHOSPHORYLASE COMPLEXES WITH TRANS-STATE INHIBITORS. A.A.Fedorov, G.A.Kicska, E.V.Fedorov, W.Shi [1], P.C.Tyler, R.H.Furneaux [2], V.L.Schramm, S.C.Almo [1], [1] Albert Einstein College of Medicine, Bronx,NY,10461,USA, [2] Carbohydrate Chemistry Team,Industrial Research Limited, Lower Hutt,New Zealand

Purine nucleoside phosphorylase (PNP) catalyzes the reversible phosphorolysis of ribonucleosides and 2'-deoxypurine ribonucleosides to the free bases and the corresponding ribose 1-phosphates. PNP is a key enzyme in the purine salvage pathway. Absence of PNP activity in humans is associated with specific T-cell immune suppression. Its key role in these two processes has made PNP an important drug design target. The structures of the calf spleen PNP bound to the transition state inhibitors immucillin-H (Ki* = 23 pM) and immucillin-G (Ki* = 72 pM) have been determined and refined at 1.5 and 2.0 A resolution respectively. The PNP complexes were obtained by co-crystallization with the inhibitors at 1:1.1 (PNP monomer: inhibitor) molar ratio. The refined structures of PNP complexes have good geometry with R factors 18.4 and 16.4%; free R-factors 23.2 and 24.6% respectively. The structures of PNP-immucillin complexes were compared with known PNP-substrate and PNP-product complexes and all conformational changes have been characterized. Ligand dependent loop 241-265 moves closer to the active site when compared to the corresponding substrate analog and product complexes; bound phosphate ion is closer to the ribose ring than in PNP-substrate analog complex; hydrogen bonds are shorter than observed in substrate analog and product complexes. Bound immucillins show that positive charge of the transition state oxocarbenium ion is stabilized by phosphate and ribose O5'; negative charge of the transition state purine ring is stabilized by hydrogen bonds donation from Asn 243 ND2 and from a water molecule to ribose O6.

P06.04.041 STRUCTURAL STUDIES OF PHOSPHONO-ACETATE HYDROLASE: A PHOSPHORUS-CARBON BOND CLEAVAGE ENZYME. M.M. Benning [1], A. Kim [2], D. Dunaway-Mariano [2] and H.M. Holden [1]. [1] Department of Biochemistry, University of Wisconsin, Madison, Wisconsin 53705. [2] Department of Chemistry, University of New Mexico, Albuquerque, New Mexico 87131.

Phosphonates are naturally occurring organophosphorus compounds that are similar to phosphate esters but contain a direct phosphorus-carbon linkage. The P-C bond is resistant to acid- and base-catalyzed hydrolysis as well as to enzymes that hydrolyze phosphate esters The phosphonoacetate hydrolase catalyzes the production of acetate and inorganic phosphate from phosphonacetate via a metal ion assisted hydrolytic cleavage of the P-C bond. The native enzyme was isolated from Pseudomonas fluorescens and crystallizes in the monoclinic space group $P2_1$ with cell constants of a=57 Å, b=128 Å, c=138 Å, b=95o. We have also crystallised the enzyme in the presence of an inhibitor, phosphonoformate. These crystals belong to the orthorhombic space group $P2_12_12_1$ with cell constants of a=115 Å, b=128 Å, c=138 Å. The crystal structure of the hydrolase will be presented.

P06.04.042 FUNCTION OF DIHYDROOROTATE DEHYDROGENASES (DHOD). S.Norager and S.Larsen, Centre for Crystallographic Studies, Department of Chemistry, University of Copenhagen, Universitetsparken 5, DK-2100 Copenhagen O, Denmark. O.Bjornberg and K.F.Jensen, Center for Enzyme Research, Institute of Molecular Biology, University of Copenhagen, Solvgade 83H, DK-1307 Copenhagen K, Denmark.

The DHODís catalyse the oxidation of (S)-dihydroorotate to orotate through reduction of their prosthetic FMN group. This is the only redox-reaction in the *de novo* biosynthesis of pyrimidine nucleotides. From the known sequences the DHODís can be split into two main families. The family 1 enzymes are located in the cytosol, while the family 2 enzymes are membrane associated. The family 1 enzymes can be further divided into two subgroups A and B. The crystal structures have been determined for the two DHODís from *Lactococcus lactis* that are representative of group A[1] and B[2]. The A type enzyme exists as a homodimer and has the same FMN associated binding site for the substrate and the e-acceptor. The B type enzyme is a heterotetramer. Substrate binding takes place at the two FMN containing subunits, that resemble the DHODA structure. This dimer interacts with the other two subunits that each contain a FAD and a [2Fe-2S] cluster. The presence of FAD in these latter subunits enables the enzyme to use NAD^+ as e-acceptor.

The structure of the DHODA enzyme complexed with the product orotate[3] showed that orotate stacks above the FMN isoalloxazine ring system and is attached by hydrogen bonds to the surrounding residues. Several DHODA mutants have been prepared and characterised kinetically to elucidate the reaction mechanism, and for two of these, N67A and P56A, the crystallographic studies are currently in progress. Asn67 forms a hydrogen bond to the orotate pyrimidine ring, and influences the orientation of the orotate in the binding site. Pro56 is part of a flexible loop, which covers the orotate binding cavity. The P56A mutant has a much lower K_M for the binding of orotate than the wild type enzyme.

P06.04.043 CRYSTAL STRUCTURE OF BRASSICA THIOREDOXIN. K.K. Kim, S. C. Ha, Y. O. Hong and S. Y. Lee. Plant Molecular Biology and Biotechnology Research Center, Gyeongsang National University, Chinju 660-741, Korea

Thioredoxin is a ubiquitous protein and has a large number of known functions. Generally, it acts as a hydrogen donor for several essential reductase via thiol-redox mechanism. Several crystal structures of thioredoxin from different species, including *E. coli,* human, cyanobacteria and green alga, were determined. Although they show different functions and substrate specificities, the overall structure of thioredoxin is well conserved among species. Plant has many isoforms of thioredoxin and those may be required for modulating their substrate specificities.

Cytosolic thioredoxin h from the plant *Brassica campestris* (btrxh) has been studied for understanding the substrate specificity in plant thiol-redox reaction. The crystal structure of oxidized btrxh was solved by molecular replacement starting from the crystal structure of human thioredoxin. Current model has been refined to a crystallographic R-factor of 23 % (R-free = 27 %) at 2.3 A resolution. It has a typical thioredoxin fold which consists of a five-stranded β-sheet core surrounded by four α helices. The active site is well conserved either in sequence (46-WCGPC-50) and in structure with other thioredoxins. Interestingly, the first β strand in symmetry equivalent molecule

makes a tight contact to the groove close to the active site. That is the mimic of thioredoxin-substrate interaction which was observed in human thioredoxin-NFκB complex. Therefore, it is postulated that a btrxh-substrate interaction is similar to the human thioredoxin-substrate interaction, and these interactions could be shared in thioredoxin families.

P06.04.044 THREE-DIMENSIONAL STRUCTURE OF THE ENZYME DIAMINOPIMELATE EPIMERASE FROM *HEMOPHILUS INFLUENZAE*. Maurizio Cirilli*^, Renjian Zheng^, Giovanna Scapin~, John S. Blanchard^, *Istituto Strutturistica Chimica, CNR-Roma, 00016 Monterotondo St. (Roma), Italy, ^Department of Biochemistry, Albert Einstein College of Medicine, 1300 Morris Park Avenue, Bronx, New York 10461, ~Merck Research Laboratories, RY50-105, P.O. Box 2000, Rahaway, New Jersey 07065.

The crystallographic structure of Diaminopimelate epimerase (E.C. 5.1.1.7) from the bacteria *Hemophilus Influenzae* has been solved at 2.7 Å resolution by Multiple Isomorphous Replacement . The enzyme crystallizes in the C2221 space group with cell parameters a=102.1 Å, b=115.4 Å, c=66.3 Å and one molecule in the asymmetric unit. The refined model had a conventional R factor of 19.0% and a R_{free} factor of 24.2%. The 274 amino acid residues enzyme consists of two structurally homologous domains each containing eight β-strands and two α-helices. This arrangement of secondary structure elements give rise to a completely new fold as resulted by searching for possible matches in PDB database by DALI server. The two domains are highly homologous and are related by a pseudo two-fold symmetry axis. The superimposed domains have an rms deviation of 1.7 Å.

P06.04.045 CRYSTALLOGRAPHIC STUDIES ON SHIKIMATE DEHYDROGENASE. J. K. F. Maclean, A. J. Lapthorn, Dept. of Chemistry and Biochemistry, University of Glasgow, Glasgow, G12 8QQ, UK. and J. R. Coggins, IBLS, University of Glasgow, Glasgow, G12 8QQ, UK.

Shikimate Dehydrogenase (SDH) is the fourth enzyme of the shikimate pathway, and catalyses the NADPH-linked reduction of 3-dehydroshikimate to shikimic acid. We are engaged in an effort to determine the structures of several shikimate pathway enzymes, both to increase our understanding of the enzyme mechanisms, and to achieve a better understanding of the process of molecular recognition. SDH is one of only two such enzymes whose structures are still unresolved. We hope that the structure of SDH will provide the starting point for a programme of rational inhibitor design.

SDH crystals grow in space group C2, with a=110.0Å, b=139.5Å, c=102.6Å, β=122.24°. The packing density is $2.8Å^3Da^{-1}$, which corresponds to four molecules per assymetric unit. These crystals diffract to 2.2Å and exhibit interesting pseudosymmetry. While the true lattice is C-centred monoclinic, it is indistinguishable from a larger F-centred orthorhombic lattice at low resolution. We have used this observation to derive matrices which describe the 222 non-crystallographic symmetry within these crystals. These, in conjunction with phase information from several heavy atom soaks, have been used to generate promising initial averaged electron density maps. We will present the recent progress in our attempt to determine the three-dimensional structure of SDH.

P06.04.046 STRUCTURE/FUNCTION STUDIES ON SHIKIMATE KINASE. A. J. Lapthorn, J. K. F. Maclean, Dept. of Chemistry and Biochemistry, University of Glasgow, Glasgow, G12 8QQ, UK. and D. J. Boam and J. R. Coggins, IBLS, University of Glasgow, Glasgow, G12 8QQ, UK.

Shikimate kinase catalyses the fifth reaction on the shikimate pathway, in which shikimic acid is phosphorylated to produce shikimate 3-phosphate, using ATP as a co-substrate. The shikimate pathway is essential for the biosynthesis of aromatic compounds in plants, microorganisms and apicomplexan parasites. However it is absent from animals and is therefore an attractive target for the design of novel antibiotics and herbicides.

We have previously determined structures of shikimate kinase from the plant pathogen *Erwinia chrysanthemi* complexed with ADP and shikimic acid [1]. From these structures we have designed and generated a series of active site mutants to probe the contribution of various amino acid residues to substrate recognition and catalysis. Several of these mutants, which have significantly reduced catalytic activity of the enzyme, have been crystallised to date.

The structure of the p-loop mutant K15M has been solved and refined at 2.5Å resolution. The enzyme crystallises in space group $C222_1$, a=43.0Å, b=75.1Å, c=106.1Å, with a single molecule in the assymmetric unit, corresponding to a solvent content of 37%. This structure is of particular interest as the mutation results in an unexpected change in the overall conformation of the p-loop. To our knowledge, this is the first structure of a kinase p-loop mutant.

P06.04.047 CRYSTALLIZATION AND STRUCTURE DETERMINATION OF ECTI, A SERINE PROTEASE INHIBITOR FROM ENTEROLOBIUM. R.C. Garratt, M.C. Nonato, M. Bonfadini, and L.M. Beltramini [1], and I.F.C. Batista, M.U. Sampaio and C.A.M. Sampaio [2], [1]Instituto de Física de São Carlos, Universidade de São Paulo, São Carlos 13560-250, SP, Brazil, [2] Depto. Bioquímica, Universidade Federal de São Paulo, UNIFESP/EPM, São Paulo, SP, Brazil

Protein enzyme inhibitors are distributed in a large range of biological materials. They have been studied in detail in part because of their use as tools in the study of enzyme mechanisms. Seed serine protease inhibitors are divided according to sequence/structural properties into six superfamilies : Kunitz, Bowman-Birk, Potato I and II, Squash and Cereal inhibitors. The Enterolobium contortisiliquum trypsin inhibitor (EcTI) belongs to the plant Kunitz inhibitor family, and consists of 174 amino acid residues and contains two disulphide bridges. It is homologous to other trypsin inhibitors from the same family, such as STI (Soybean trypsin inhibitor) and ETI (Erithryna caffra trypsin inhibitor).

EcTI was purified to the homogeneity by acetone precipitation, ion-exchange and gel filtration chromatographs. Crystals of EcTI were obtained at 19 ºC, by the vapour diffusion technique with 15%PEG 8000 / 0.5M Lithium sulfate as precipitating agent.

The crystals obtained with EcTI belong to the space group $P2_1$ and diffract up to 2.4Å resolution on capillary mounting using a rotating anode source. The structure determination by molecular replacement using 1TIE (Erythrina Trypsin Inhibitor - Kunitz De-3) as a model indicates the presence of one monomer in the asymmetric unit. The structure of EcTI presents the expected b-trefoil motif.

P06.04.048 CRYSTAL STRUCTURE OF *E. COLI* CYANASE AT 1.65 Å DETERMINED USING MAD PHASING. A. Joachimiak[1], M.A. Walsh[1], A. Perrakis[2] & P.M. Anderson[3], [1]Center for Mechanistic Biology and Biotechnology, Argonne National Laboratory, Argonne IL 60439, USA, [2]European Molecular Biology Laboratory, Grenoble, France, [3]Dept. Biochemistry, University of Minnesota-Duluth, Duluth, MN 55812, USA

Cyanase, a homo-decamer of 17-kDa subunits, is an inducible enzyme in *Escherichia coli* that catalyzes the reaction of cyanate with bicarbonate to produce ammonia and carbon dioxide. The enzyme crystallizes in the triclinic space group P1 with unit cell dimensions of a = 76.34 Å, b = 81.03 Å, c = 82.30 Å, α = 70.3°, β = 72.23° and γ = 66.43° and contains one 170-kDa decamer in the AU and 40 potential selenium sites. A four-wavelength MAD experiment was collected to 2.25 Å resolution at 100 K at the Argonne National Laboratory Structural Biology Center's undulator beamline at the Advanced Photon Source. The positions of the selenium atoms were found automatically (CNS & CCP4) and maps of high quality were produced. The solvent-flattened map (DM) was used as input to the wARP procedure, which extended and improved phases and produced an initial protein model. The model was refined (REFMAC) against data collected to 1.65 Å resolution (R=15.2%, R_{free}=19.0%). Structures of the enzyme complexed with chloride (cyanate analogue) and oxalate (proposed transition state analogue), were also determined. The structures show that active site of cyanase is formed by the side chains of four adjacent subunits of the homo-decamer. The combination of an x-ray source with high brilliance, a large mosaic CCD area detector with a rapid read-out time, and recent developments in crystallographic software have provided a platform for accelerated crystal structure determination and refinement.

This work was supported by the U.S. Department of Energy, Office of Biological and Environmental Research, Under Contract W-313-109-ENG-38.

P.06.04.049 CRYSTAL STRUCTURE OF HYALURONIDASE, A MAJOR ALLERGEN FROM BEE VENOM. Z. Markovič-Housley, T. Schirmer, L.N. Soldatova, U. R. Müller. Biocenter, Basel & Ziegler Spital, Bern, Switzerland; FDA, Rockville, Maryland, USA.

Hyaluronidase from bee venom (Hya) is a hydrolase that specifically cleaves the β-1,4-glycosidic bond of hyaluronic acid, the most abundant glycosaminoglycan of vertebrate extracellular spaces, thereby facilitating the penetration of venom constituents into the skin. Hya is a major allergen of bee venom which can induce serious systemic IgE-mediated anaphylactic reactions in humans. The atomic structure of Hya is the first step towards identifying epitope residues responsible for the IgE-mediated potency of hyaluronidase and thereafter, the development of allergen-specific forms of therapy. The crystal structure of recombinant (*Baculovirus*) bee venom Hya has been determined at a resolution of 2.0 Å by the method of multiple isomorphous replacement and represents the first structure of any member of the glycosidase family 56. The overall fold resembles an $(\beta/\alpha)_8$ barrel, common among many hydrolases, with the exception that only seven strands form the barrel, and thus, the barrel appears open on one side. The active site residues Asp110 and Glu112 are located at the C-terminal end of β-strand 4, in a large groove on the protein surface. These residues are conserved amongst hyaluronidases of bee and hornet (56 % sequence identity) and the related PH-20 proteins from mammalian testis and plasma (20% sequence identity). In most glycosidases, two carboxylates are required for acid/base catalysis and the hyaluronidases are no exception: mutation of Asp111 and Glu113 of human sperm PH-20 protein (equivalent to Asp110 and Glu112 in Hya) leads to an inactive protein. A number of aromatic residues line both sides of the active site groove to form a hydrophobic surface that is well positioned to participate in the binding of sugars through nonpolar interactions. The groove (about 30Å x 9Å) appears to be large enough to accommodate a hexasaccharide of hyaluronic acid, which is the smallest substrate.

P06.04.050 X-RAY CRYSTALLLOGRAPHY OF MAJOR NITROREDUCTASE FROM *ESCHERICHIA COLI* (NfsA). Toshiro Kobori, Woo Cheol Lee, Takako Akagi, Departments of Applied Biological Chemistry and Biotechnology, Graduate School of Agricultural and Life Sciences, University of Tokyo, Tokyo 113-8657, Japan, Hiroshi Sasaki, Biotechnology Research Centre, University of Tokyo, Tokyo 113-8657, Japan, Shuhei Zenno, Kaoru Saigo, Department of Biophysics and Biochemistry, Graduate School of Science, University of Tokyo, Tokyo 113-0033, Japan, and Masaru Tanokura, Departments of Applied Biological Chemistry and Biotechnology, Graduate School of Agricultural and Life Sciences, University of Tokyo, Tokyo 113-8657, Japan.

NfsA is the major oxygen-insensitive NAPDH:nitrocompound oxidoreductase (nitroreductase) from *Escherichia coli*. Oxygen-insensitive niroreductases catalyze the reduction by two electron transfer mechanism and are not inhibited by oxygen. Biochemical studies have suggested that NfsA is an FMN-containing flavoprotein with a molecular mass of approximately 26kDa and can use only NADPH as an electron donor, in contrast to NfsB, which is another nitroreductase in *E. coli* and can use either NADH or NAPDH as an electron donor. We have overexpressed NfsA protein in *E. coli* and crystallized NfsA in the presence of FMN by the vapor diffusion method using polyethylene glycol 6000 as a precipitant at 5°C. The obtained crystals had a plate-like shape. The crystals belonged to the triclinic space group *P*1 with cell dimensions, *a* = 52.2 Å, *b*=52.7Å, *c*=53.3Å, α = 75.1°, β = 60.1°, γ = 60.5°. Assuming that there are two molecules per unit cell, the crystal volume per unit molecular mass (*V*m) and the solvent content are 1.98Å^3/Da and 37.9% respectively. Because biochemical experiments have suggested that NfsA acts as a dimer in the solution, the crystals should contain one dimer in a unit cell. The crystals diffracted X-rays to at least 2.3Å resolution, by using the Weissenberg camera for macromolecular crystallography with a synchrotron radiation in the Photon Factory at High Energy Accelerator Research Organization, Tsukuba, Japan. Structural analysis is in progress by the molecular replacement method.

P06.04.051 X-RAY STRUCTURE ANALYSIS OF PYRUVATE FORMATE-LYASE AT 5 Å RESOLUTION. Andreas Becker, Klaus Scheffzek and Wolfgang Kabsch, Max-Planck-Institut für medizinische Forschung, Abteilung Biophysik, Jahnstraße 29, D-69120 Heidelberg, FRG, and A.F.Volker Wagner, Sabine Schulz and Joachim Knappe, Institut für Biologische Chemie/ Biochemie Zentrum Heidelberg, Universität Heidelberg, Im Neuenheimer Feld 501, D-69120 Heidelberg, FRG.

Pyruvate formatelyase (PFL, a_2, 170kDa), a key enzyme of energy-metabolism in anaerobic E.coli cells, synthesizes Acetyl-CoA (and formate as coproduct) from pyruvate and CoA. It catalyzes the cleaveage of the C1-C2-carbon bond of pyruvate via a reversible radical mechanism. A crucial catalytic element of the enzyme is a free and stable organic radical located at Gly734 [1].

So far only two structures of a radical enzymes are known; ribonucleotide reductase class Ia from *E.coli* [2] and class Ib from *Salmonella typhimurium* [3] contain a tyrosyl-radical in R2-subunit, which is Fe(III) stabilized. In contrast the glycyl-radical in PFL is only stabilized by the 3D-structure of the protein.

Large PFL crystals were obtained by the dialysis method using PEG as precipitant. They belong to the tetragonal space

group $P4_32_12$ or its enantiomorph (a=b=160Å, c=161Å) with one PFL homodimer per asymmetric unit.

Using synchrotron radiation (EMBL c/o DESY, BW7B) crystals diffract to 2.6Å. In our laboratory using rotating anode radiation we have collected a complete native dataset to 3.4Å resolution and a number of heavy atom derivative datasets.

We prepared heavy atom datasets from crystals of mutant proteins, where cysteins at positions 122, 159 and 524 are replaced by serine. All of the heavy atom derivatives heve been solved at 6Å resolution, which led to unique identification in the primary sequence of each heavy atom sites. The two polypeptide chains of the dimer are related by a pure two-fold rotation (without screw component). At present the structure has been solved at 5Å resolution showing a number of distinctive a-helices and b-sheets.

The identification of the heavy atom labelled cysteins in the map are expected to simplify the construction of the atomic model.

P06.04.052 INHIBITION OF HEXOKINASE ACTIVITY BY DECAVANADATE: CRYSTALLOGRAPHIC AND KINETIC STUDIES. Agnete la Cour, Oren P. Anderson, Debbie C. Crans, and Boyan Zhang, Department of Chemistry, Colorado State University, Fort Collins, Colorado 80523, USA.

Hexokinase has been suggested to play a role in facilitating the diabetic state given its physiological function of phosphorylating glucose. We have undertaken kinetic studies in solution of a series of vanadium-containing oxometalate ions and identified these as competitive inhibitors of yeast hexokinase B, with a surprising selectivity based on charge and shape. Activity studies of yeast hexokinase B crystals suggested that the enzyme is also active in the solid state. Inhibition studies of hexokinase crystals soaked in a decavanadate solution suggested that decavanadate inhibits the enzyme in the solid state, thus indicating that decavanadate may be found in the active site of the enzyme in the crystals. We have undertaken crystallographic studies with the goal of determining the molecular interactions of species such as decavanadate with the enzyme. Yeast hexokinase B crystallizes in the orthorhombic space group $P2_12_12_1$, however with two different unit cells. We have collected low temperature data to a resolution of 1.8 Å for a prismatic crystal form (a = 58.571(6), b = 57.584(6), c = 163.263(20) Å); this form is the same as that in the previous 2.1 Å structural study [C. M. Anderson, R. E. Stenkamp, & T. A. Steitz (1978). *J. Mol. Biol*., 123, 15]. We have also collected low temperature data to 2.5 Å for a crystal of a plate-like crystal form (a = 57.90(4), b = 92.97(10), c = 213.84(6) Å) that had been soaked in a decavanadate solution. In the earlier structure determination the identities of 17% of the amino acids were not assignable. We will present a 1.8 Å structure of hexokinase B with all amino acids assigned from the known protein sequence. The data from the decavanadate-soaked crystals had not yielded a structure at the time of submission of this abstract. However, we expect to document the existence of decavanadate in the active site of the enzyme and to make a first estimation of the nature of the interactions between the decavanadate ion and the enzyme.

P06.04.053 *E. coli* ASPARTYL-tRNA SYNTHETASE - $tRNA^{Asp}$ COMPLEX: SECOND STEP OF THE AMINOACYLATION REACTION. S. Eiler, A.C. Bregeon, L. Moulinier, J.-C. Thierry and D. Moras. Laboratoire de Biologie Structurale, Institut de Génétique et de Biologie Moléculaire et Cellulaire, CNRS/INSERM/ULP, 1 rue Laurent Fries, BP 163, 67404 Illkirch Cédex, C.U. de Strasbourg, France.

The 2.4 Å resolution crystal structure of the *E. coli* aspartyl-tRNA synthetase - $tRNA^{Asp}$ with aspartyl-adenylate shows all substrates ready for the transfer of the aspartic acid moiety from the activated aspartyl-adenylate to the 3'-hydroxyl of the terminal adenosine of $tRNA^{Asp}$. Amino acid residues and water molecules involved in the specific recognition of the substrates in the enzymatic mechanism, have been identified. Most of the residues involved in the catalysis and amino acid substrate recognition are strictly conserved in all AspRSs, a few of them are only conserved within eucaryotes, archaea or eubacteria. A mechanism governing the two steps of the enzymatic aspartylation reaction common to all AspRSs but different for the role of one amino acid is proposed. The eucaryotic or archaeal serine, essential for the stabilisation of intermediate states in the two steps of the aspartylation reaction, is replaced in eubacteria by a glutamine from a different position in the catalytic site.

P06.04.054 STRUCTURAL COMPARISONS OF TYPE I 3-DEHYDRO-QUINASES. D.A.Porter, I.McNae, D.Alexeev, L.Sawyer, ICMB, The University of Edinburgh, Swann Building, Mayfield Road, Edinburgh EH9 3JR, UK and A.K.Shrive, Department of Physics, Keele University, Staffordshire ST5 5BG and I.Polikarpov, LNLS, CP 6192, 13083-970 Campinas, Brazil and J.R.Coggins, Division of Biochemistry and Molecular Biology, The University, Glasgow, G12 8QQ and A.R.Hawkins, Department of Biochemistry & Genetics, University of Newcastle, Newcastle NE2 4HH, UK

The enzyme 3-dehydroquinase (DHQase, EC 4.2.1.10) catalyses the dehydration of 3-dehydroquinate to form 3-dehydroshikimate and so introduce the first double bond in the biosynthesis of the aromatic nucleus. The mechanism proceeds by a *syn*- or *cis*-elimination for the Type I enzyme and involves an imine (Schiff base) intermediate, in contrast to the Type II enzyme that uses an entirely different mechanism. As the shikimate pathway is absent from mammals, studies of the inhibition of the constituent enzymes may provide suitable lead compounds for herbicide and antibiotic development. We have solved the crystal structure of the native Type I enzyme from *Salmonella typhi* and describe the modification to the structure that occurs upon substrate binding. This provides a basis that is used in conjunction with various solution studies to propose a detailed molecular mechanism. Further, the better studied enzyme from *Escherichia coli* has also been solved at 2.8Å resolution and we compare the two structures, particularly their active sites and subunit contacts.

We are grateful to the BBSRC for financial support.

P06.04.055 STRUCTURAL INVESTIGATION OF CYTOCHROME C'. L. Ramirez[1], P. Trieu[1], R. McNulty[1], B. Schick[1], H. Axelrod[2], K. Kantardjieff[1]. [1]Department of Chemistry & Biochemistry and W.M. Keck Foundation Center for Molecular Structure California State University, Fullerton, CA 92634. [2]Department of Physics. University of California, San Diego. La Jolla CA 92093-0319.

Cytochrome C' is a bacterial protein found in photosynthetic bacteria. The protein is a 28kDa dimer of four helix bundles. Each monomer contains four antiparallel helices, which bind a heme prosthetic group. Cytochrome C' is found in various photosynthetic bacteria and has been shown to increase in

concentration during photosynthesis. The protein has a low redox potential, which suggests that if it is involved in the electron transfer process, it is not a terminal oxidase. The heme prosthetic group is pentacoordinate and in a high spin state, further supporting its role in electron transfer. The three dimensional structure of cytochrome c' has been determined in *Rhodopseudomonas palustris* (N. Shibata *et al.* In press.), *Chromatium vinosum* (Z. Ren *et al.* In press.), *Alcaligenes denitrificans* (A.J. Dobbs *et al.* In press.), *Alicaligenes sphaeroides* (A.J. Dobbs *et al.* In press.), *Rhodobacter capsulatus* (T.H. Tahirov *et al.* J. Mol. Biol. 1996.), and *Rhodocyclus gelatinosus* (M. Archer *et al.* J. Biol. Inorg. Chem. 1997.) (inexhaustive search). A comparison of the three dimensional structures of Cyt C' displays a high similarity in tertiary structure but a low sequence homology (M. Archer *et al.* J. Biol. Inorg. Chem. 1997.). Highly conserved sequences are at the heme binding sites. Cyt C' binds small ligands such as CO and CN^-. In the case of *Chromatium vinosum,* ligand binding causes dimer dissociation (R.J. Kassner. Biochim. Biophys. Acta, 1991.). Structure elucidation will give some insight into 1.) the role of Cyt C' in electron transfer processes during photosynthesis, 2.) amino acid sequence relation to protein folding, and 3.) ligand induced dissociation.

P06.04.056 CRYSTAL STRUCTURES OF NATIVE AND E202Q MUTANT HUMAN ACETYLCHOLIN-ESTERASE COMPLEXED WITH FASCICULIN-II. G. Kryger [1], K. Giles [1,2], L. Toker [2], B. Velan [3], A. Lazar [3], C. Kronman [3], D. Barak [3], N. Ariel [3], A. Shafferman [3], I. Silman [2] and J.L. Sussman [1, 4]. [1] Department of Structural Biology, Weizmann Institute of Science, Rehovot 76100, Israel. [2] Department of Neurobiology, Weizmann Institute of Science, Rehovot 76100, Israel. [3] Israel Institute of Biological Research, Ness Ziona 70450, Israel. [4] Biology Department, Brookhaven National Laboratory, Upton, NY 11973, USA.

Knowledge of the 3D structure of human acetylcholinesterase (AChE) is of importance for drug design, in particular of anti-Alzheimer drugs, and for design of safer and more effective insecticides. A construct of recombinant human AChE (rHuAChE) was made in which the C-terminus had been truncated. This was done to facilitate crystallization by partly alleviating the problem of polymorphism, i.e. the co-expression of monomers, dimers and tetramers. Both WT rHuAChE and the E202Q mutant were expressed in HEK 293 cells, and co-crystallized as a stoichiometric complex with the polypeptide toxin, fasciculin-II (FAS-II), purified from the venom of the green mamba. Synchrotron data were collected from single cryo-cooled crystals. The WT rHuAChE/FAS-II and E202Q structures refined to 19%/25.5% and 19%/24% R/Rfree, at 2.8Å and 2.9Å resolution, respectively, using the *Torpedo californica* AChE (*Tc*AChE)/FAS-II structure as a starting model. Both structures contain ~400 solvent molecules. The WT structure shows three sugar rings at one of the three known glycosylation sites, N350. The E202Q structure shows the same three sugar rings on N350, an additional ring on N265, and residues 493-496, which are disordered in the WT structure. rHuAChE/FAS-II shows high degree of structural similarity with the two other, already published, complexes of AChE with FAS-II, viz. of *Tc*AChE and of mouse AChE, especially in the active-site region and within the aromatic gorge. Small variations can be found in some loops and in the insertion/deletion regions. Our results thus open the way to a study of subtle differences in structure which may account for species-dependent differences in specificity for substrates and inhibitors.

P06.04.057 THREE DIMENSIONAL STRUCTURE OF A DEHYDROGENASE AT 2.8Å RESOLUTION. Alpana Seal C&MB Division,S.I.N.P.,1/AF Bidhan Nagore, Calcutta 700064 India

The metabolic breakdown of long chain fatty acids, in most organisms, proceeds through beta oxidation pathway. L-3 hydroxyacyl CoA dehydrogenase is one of the four enzymes involved in mitochondrial beta-oxidation cycle which utilizes NAD as a cofactor and L-3-hydroxy- acyl CoA as substrate.

Polyalanine model from a orthorhombic form C222(1) of this dimeric 70KD protein with 5.25Å data using MIR techniques showed distinct bilobal appearance, NAD molecule being bound to the larger of the two lobes near the interface with the small lobe(1).

One 2.8 Å data set consisting of Hg (three major, three minor sites), Pt and a pseudo heavy atom derivative (NAD) were used to get MIR phases. Solvent flattened map was used to get the initial skeleton. Density modification was done using non crystallographic symmetry. Subsequent model building is underway to best fit the maps. NAD enzyme interaction and possible mode of interactions between fatty acid and the enzyme will be described.

P06.04.058 CRYSTAL STRUCTURE OF BACILLUS CEREUS β-AMYLASE AND ITS COMPLEXES WITH SUBSTRATE ANALOGS. T. Oyama, Y. Kishimoto, and Y. Nitta, College of Agriculture, University of Osaka Prefecture, Sakai, Osaka 599-8531, Japan, and Y. Takasaki, Faculty of Engineering, Miyazaki University, Miyazaki 889-2155, Japan, and M. Kusunoki, Institute for Protein research, Osaka University, Suita, Osaka 565-0871, Japan.

The crystal structure of β-amylase from *Bacillus cereus* var *mycoides* was determined by multiple isomorphous replacement and was refined to a final *R*-factor of 0.186 for 102,807 reflections with $F/\sigma(F) \sim 2.0$ at 2.2Å resolution with r.m.s. deviations from ideality in bond lengths and bond angles of 0.014 Å and 3.0°, respectively. The β-amylase molecule folds into three domains of A, B, and C. Domain B consists of a $(\beta/\alpha)_8$ barrel structure. Domain C has a similar fold to raw starch binding domains of cyclodextrin glycosyltransferase and glucoamylase. One calcium ion is bound in domain A and is not involved in catalysis.

To understand substrate binding mode, we determined crystal structures of complexes of the β-amylase with three kinds of substrate analogs of maltose, Glc-Glc-Xyl, and α-cyclodextrin, and the complexes showed different binding modes and conformational chugs of the enzyme. Maltose molecules bound to subsites 1 and 2 in the catalytic cleft and site B on domain B distant from the catalytic cleft. In the maltose complex, a flexible loop of residues 93-97 moved 10 Å into a closed form, shielding the catalytic site from the solvent.

To clarify the role of the catalytic residues of Glu172 and Glu367, we determined crystal structures of complexes of the β-amylase with two kinds of specific inhibitors of 2',3'-epoxypropyl-α-D-glucopyranoside and 3',4'-epoxybutyl-α-D-glucopyranoside, leading to the conclusion that Glu172 and Glu367 are in the non-dissociated and dissociated form, respectively.

P06.04.059 THE REACTION AND INHIBITION MECHANISM OF *DROSOPHILA* ADH BY X-RAY CRYSTALLOGRAPHY. NAD-KETONE ADDUCT AT 1.4Å. J. Benach and R. Ladenstein, Center for Structural Biochemistry, NOVUM, Karolinska Institutet, S-141 57 Huddinge, Sweden, S. Atrian and R. Gonzàlez-Duarte, Dept. of Genetics, University of Barcelona, E-08028 Barcelona, Spain.

Drosophila alcohol dehydrogenase (DADH) is an NAD^+ dependent enzyme that catalyzes the oxidation of alcohols to aldehydes/ketones. DADH is the member of the short-chain dehydrogenases/reductases family (SDR) for which the largest amount of biochemical data has been gathered during the last three decades. The crystal structures of one binary form (NAD^+) and three ternary complexes with NAD^+·acetone, NAD^+·3-pentanone and NAD^+·cyclohexanone were solved at 2.4 Å, 2.2 Å, 1.4 Å and 1.6 Å resolution , respectively. From the molecular interactions observed, the reaction mechanism could be inferred. The structure of DADH undergoes a conformational change in order to bind the coenzyme. Furthermore, upon binding of the ketone, a region that was disordered in the apo form (186-191) [1] gets stabilized and closes the active site cavity by creating either a small helix (NAD^+·acetone, NAD^+·3-pentanone) or an ordered loop (NAD^+·cyclohexanone). The active site pocket comprises a hydrophobic bifurcated cavity which explains why the enzyme is more efficient in oxidizing secondary aliphatic alcohols (preferably R form) than primary ones. Difference Fourier maps showed that the ketone inhibitor molecule has undergone a covalent reaction with the coenzyme in all three ternary complexes. Due to the presence of the positively charged ring of the coenzyme (NAD^+) and the residue Lys^{155}, the amino acid Tyr^{151} is in its deprotonated (tyrosinate) state at physiological pH. Tyr^{151} can subtract a proton from the enolic form of the ketone and catalyze a nucleophilic attack of the C_α atom to the C4 position of the coenzyme creating an NAD-ketone adduct. The binding of these NAD-ketone adducts to DADH accounts for the inactivation of the enzyme. The catalytic reaction proceeds in a similar way, involving the same aminoacids as in the formation of the NAD-ketone adduct. The pKa value of 9-9.5 obtained by kinetic measurements on apo DADH can be assigned to a protonated Tyr^{151} which is converted to an unprotonated tyrosinate (pKa 7.6) by the influence of the positively charged nicotinamide ring in the binary enzyme-NAD^+ form. pH independence during the release of NADH from the binary complex enzyme-NADH can be explained by either a lack of electrostatic interaction between the coenzyme and Tyr^{151} or an apparent pKa value for this residue higher than 10.0. Finally, from the available crystallographic and biochemical data, Ser^{138} -also conserved in the SDR family- might assist the proper positioning of the hydroxyl or carbonyl group of the substrate.

P06.04.060 ASV INTEGRASE: STRUCTURAL SECRETS OF ITS CATALYTIC DOMAIN. J. Lubkowski, F. Yang, Z. Dauter, J. Alexandratos, and A. Wlodawer, NCI-FCRDC, ABL-Basic Research Program, Frederick, MD 21702, USA, M. Andrake, G. Merkel, and A. M. Skalka, Institute for Cancer Research, Fox Chase Cancer Center, Philadelphia, PA 19111, USA

We are reporting atomic resolution crystal structures of the core domain of integrase (IN) from avian sarcoma virus (ASV) and its mutant Asp64→Asn, as well as high resolution structures of three other active site mutants, →Asn, Asp121→Cys, and Glu157→Gln. Altogether, the new structural information presented here is based on refinement of nearly 15 structures, using synchrotron quality x-ray data. The resolution of these structures varies between 1.0 Å and 1.8 Å. These unparalleled x-ray data for ASV IN deliver new structural information about the flexible, active site loop of the enzyme and clear some inconsistences in the description of this fragment previously reported. The very high resolution and quality of these structures allows a complete description of the water structure around the catalytic core domain of ASV IN, the dynamic properties of this enzyme, the multiple conformations of disordered residues, and non-solvent molecules bound to the enzyme. The detailed dynamic description of the flexible active site region, in particular the loop formed by residues 144-154, suggests the conformational changes which may be associated with substrate binding. The pH dependence of active site loop mobility provides a new, more complete interpretation of the pH vs. activity profile observed for ASV IN. Structures of the active site mutants clearly show the factors responsible for loss of their catalytic activity. The chemical substitution of few atoms, followed by structural changes of substituted residues for Asp64→Asn, was found to suppress completely capability of these mutants to bind divalent metal (Mn, Mg) cations, necessary for catalysis.

Because these are the highest resolution structures reported for the core domain of ASV IN so far and because of the very careful refinement protocol applied, the structures reported here should be considered as the reference for future studies of this enzyme.

P06.04.061 CONFORMATIONAL FLEXIBILITY IN A NEW CRYSTAL FORM OF BILE SALT ACTIVATED LIPASE. Julian C.-H. Chen, Larry J.W. Miercke, Jolanta Krucinski, Robert M. Stroud. Graduate Group in Biophysics and Department of Biochemistry and Biophysics, Box 0448, UCSF, San Francisco, CA 94143-0448

The conformational changes associated with activation of lipases has been studied extensively, however, only a couple of lipases have been studied in both the inactive and activated forms.

We have obtained a new crystal form of bovine pancreatic bile salt activated lipase. The asymmetric unit is composed of three monomers, all in different conformations. Taken together with two structures of the protein solved earlier, we observe multiple conformations of the bile salt binding loop. This suggests that lipases may not necessarily have one particular closed state, but that the activation process stabilizes the open, substrate-accessible conformation. These structures also show a ~1.0 A rmsd between them, implying that domain movements may be also be involved during activation of cholesterol esterase, as opposed to localized changes found in other lipases.

P06.04.062 FARNESYL PROTEIN TRANSFERASE COMPLEXED WITH A CAAX PEPTIDE AND FPP ANALOGUE. C. Strickland, W. Windsor, R. Syto, L. Wang, R. Bond, Z. Wu, J. Schwartz, L. Beese, H. Le, P. Weber, Department of Structural Chemistry, Schering-Plough Research Institute, 2015 Galloping Hill Rd, Kenilworth NJ, 07033

The crystallographic structure of Acetyl-Cys-Val-Ile-selenoMet-COOH and alpha-hydroxyfarnesylphosphonic acid (HFP) complexed with rat farnesyl protein transferase (FPT) is reported. In the ternary complex, the bound substrates are within van der Waals contact of each other and the FPT enzyme. HFP binds in an extended conformation in the active site cavity where positively-charged sidechains and solvent molecules interact with the phosphate moiety and aromatic sidechains pack adjacent to the isoprenoid chain. The backbone of the bound CaaX peptide adopts an extended conformation and the sidechains interact with both FPT and aHFP. The cysteine sulfur of the bound peptide coordinates to the active site zinc. Overall, peptide binding and recognition appear to be dominated by sidechain interactions. Comparison of the structures of the ternary complex and

unliganded FPT shows that major rearrangements of several active site side-chains occur upon substrate binding.

P06.04.063 THE THREE-DIMENSIONAL STRUCTURE OF R-PHYCOERYTHRIN FROM *Gracilaria chilensis* AT 2.2 Å RESOLUTION. M. C. Bunster B., J.. A. Martínez-Oyanedel, C. Contreras-Martel and J.C.Fontecilla-Camps. Laboratorio de Biofísica Molecular, Facultad de Ciencias Biológicas, Universidad de Concepción, Casilla 160-C Concepción, Chile , and Laboratoire de Cristallographie et Cristallogenese des Proteines, Institut de Biologie Structurale J. P. Ebel, CEA/CNRS, Grenoble, France.

The three dimensional structure at 2.2 Å resolution, of R-phycoerythrin from *Gracilaria chilensis* one of the components of phycobilisomes, has been solved by X-ray diffraction methods. This is the first crystallographic report produced by our group in Chile, with the collaboration of the group in Grenoble for the data adquisition.

The protein was crystallized by vapor diffusion using sitting drops insets, with HEPES buffer at pH 7.0 and ammonium sulfate as precipitant. Red crystals grew after three weeks; they were used for macroseeding under the same conditions. The crystal diffracted to 2.2 Å resolution using synchrotron radiation at beamline BM14 of the European Synchrotron Radiation Facility at Grenoble.

The data were collected under cryogenic conditions(100ºK)with a completness of 98.6%. The crystals are rhombohedral, space group R3, with unit cell parameters a = b= 187 Å , c = 59.1 Å, $\alpha = \beta = 90º$ y $\gamma = 120º$ .The structure of R-phycoerythrin from *Polysiphonia urceolata* were used for molecular replacement to obtain the phases. The non-crystallographic symmetries were used in the refinement of the model.

The electron density maps show a high predominance of helical regions in the α and β subunits, and the chromophores are clearly defined. At this moment we have refined to a R factor of 34% and a R_{free} of 35% .

We will present the complete structure of the $\alpha\beta$ heterodimer and a model for the functional unit.

This work was supported by Dirección de Investigación, Universidad de Concepción 973172-1 and the collaboration Program Chile-France ECOS -CONICYT PC96B02.

P06.04.064 ALLOSTERIC MECHANISM OF THE MOLECULAR CHAPERONIN GroEL. Jianpeng Ma[1], Zhaohui Xu[2], Paul B. Sigler[2], and Martin Karplus[1] [1]Department of Chemistry and Chemical Biology, Harvard University, 12 Oxford St., Cambridge, MA02138. [2]Department of Molecular Biophysics and Biochemistry, Howard Hughes Medical Institute, Yale University, New Haven. CT06510

The chaperonin GroEL/GroES assisted protein folding cycle appears to involve large allosterically coordinated domain movements. To supplement the data available from the structures of stable intermediates, normal mode and targeted molecular dynamics simulations have been used to study the internal motions of GroEL.

Normal mode analyses of individual subunits and a multisubunit construct demonstrate that the observed displacements of the domains (hinge bending, twisting) arise from the intrinsic flexibility of the subunits. Simulations of the transition from the "closed" (ligand-free) to the "open" (GroES-bound in one ring) crystal structure show the transients that occur and provide stereo-chemical insights into biochemical and mutagenesis studies of the allosteric behavior of the GroEL assembly.

P06.04.065 CRYSTALLOGRAPHIC STUDIES ON THE COMPLEX CHEY-CHEA124-257. P. Gouet, N. Chinardet, M. Welch, L. Mourey, V. Guillet and J.P. Samama, Groupe de Cristallographie Bologique, IPBS-CNRS, 205 route de Narbonne, 31077 Toulouse Cedex, France

The histidine kinase, CheA, and the response regulator, CheY, are members of the two-component systems, which mediate signal transduction in prokaryotes and a few eukaryotes. These two proteins are part of the chemotaxis pathway. CheY regulates the rotation of the flagella and therefore the motion of the bacteria.

The protein CheA from *E. coli*, 71 kDa in molecular weight, is made of several functional domains connected by flexible linkers. The second domain, residues 124-257, also termed P2, is responsible for the molecular recognition of CheY. This response regulator, 14 kDa in molecular weight, consists of a single domain containing an essential aspartate residue, Asp57, whose phosphorylation by CheA leads to the activation of the protein.

Structural information on histidine kinases is limited, and the structure of the CheY-P2 complex was the first report of a protein complex in the two-component systems [1]. We have recently solved the structure of this complex to 2.1 Å in a space group of higher symmetry, $P2_12_12_1$. Cell parameters are a=53.8 Å b=76.6 Å c=157.6 Å and the asymmetric unit contains 2 molecules of complex. Water molecules have been positioned, revealing a specific pattern in the active site of CheY. Further experiments showed, that this pattern can change upon phosphorylation.

1. M. Welch, N. Chinardet, L. Mourey, C. Birck & J.P. Samama (1998). Nature Struct. Biol., **5**, 25-28.

P06.04.066 X-RAY CRYSTAL STRUCTURE OF A DECAMERIC C-TYPE LECTIN FROM RATTLESNAKE VENOM. John R. Walker[1], Bhushan Nagar[1], N. Martin Young[2] and James M. Rini.[1] [1]Departments of Molecular & Medical Genetics & Microbiology and Biochemistry, University of Toronto, Toronto, Ontario, M5S 1A8, Canada, and [2]Institute for Biological Sciences, National Research Council, Ottawa, Ontario, K1A 0R6, Canada.

The C-type lectin domain is found in proteins mediating a number of biological recognition processes including immune surveillance, lymphocyte homing, and receptor mediated endocytosis. Like other carbohydrate binding proteins, the C-type lectins use multivalency to increase the affinity and selectivity for their oligosaccharide ligands. In many snake venoms, C-type lectins appear to assist in the disruption of hemostasis. Western diamondback rattlesnake (*Crotalus atrox*) venom, for example, contains an oligomeric galactose-binding C-type lectin (RSL) which is a potent platelet activator.

We have solved the structure of RSL in two different $C222_1$ crystal forms by a combination of heavy atom methods and molecular replacement. The first form is a thiodigalactoside co-crystal (a=110Å, b= 151Å, c=95Å, resolution=2.4Å), while the second form is a lactose co-crystal (a=63Å, b=179Å, c=138Å, resolution=2.2Å). In both cases, the lectin is found to be a decamer composed of two 5-fold symmetric pentamers related by a crystallographic 2-fold rotation axis. Each monomer of the decamer possesses the canonical C-type lectin fold. The two pentameric disks (each 32Å thick, 104Å in diameter) are held together by five C86-C86 disulfide crosslinks connecting monomers on opposing pentamers. A considerable cavity, lined by acidic residues, is formed in the interface between the disulfide linked pentamers. With the exception of that arising from the bridging disulfides, no surface area is buried between opposing pentamers. In contrast, approximately ~1200 $Å^2$ of surface area on each monomer is buried by protein-protein contacts within the

pentamer. The ten carbohydrate-binding sites located on the rim of the decamer suggest a role for multivalent interactions.

P06.04.067 CRYSTALLIZATION OF REACTION CENTER WITH LIGHT-HARVESTING PROTEINS 1 FROM RHODOPSEDOMONAS VIRIDIS. Takayuki Odahara, Kazuaki Harata Biomolecular Department, National Institute of Bioscience and Human-Technology, 1-1 Higashi, Tsukuba, Ibaraki, 305-8566 Japan

To fully understand the functions of proteins, it is essential to determine their tertiary structures. Integral membrane proteins, embedded in lipid bilayer of biomembranes in well organized manner, fulfill fundamental biological functions such as energy conversion, chemical sensing, and ion transport. Most of crystals of integral membrane proteins have been obtained by the empirical search of the crystallization condition based on a try and error method. In order to break through such a situation and to get a rational guideline for the crystallization, it is necessary to derive useful common features of the crystallization conditions previously succeeded. So far we have systematically determined solubility diagrams for several integral membrane proteins in different detergents, precipitants and temperatures. It was shown that the prediction of the solubility of amorphous precipitate, which provides useful information for the choice of crystallization conditions, is possible.

There are still open questions concerning the initial energy transfer from the light-harvesting protein 1 to reaction center in the first step of the photosynthetic reaction in purple bacteria. We applied our guideline to the crystallization of the complex of those integral membrane proteins and ten different crystallization conditions of the protein were obtained. We are characterizing those crystals by the X-ray diffraction.

P06.04.068 CRYSTALLOGRAPHIC STUDIES OF THE INTERMEDIATE FILAMENT PROTEIN VIMENTIN. S.V. Strelkov, P. Burkhard, P.M. Steinert[1], N. Geisler[2], H. Herrmann[3], and U. Aebi, M.E. Müller Institut, Biozentrum der Universität Basel, 4056 Basel, Switzerland,[1]NIH, Bethesda, [2]Max Planck Institute for Biophysical Chemistry, Göttingen, [3]German Cancer Research Center, Heidelberg.

We report on the progress with the structure determination of vimentin, the first intermediate filament (IF) protein [1,2] to be studied by X-ray crystallography. Until now, the IF proteins resisted a successful crystallisation because of (*i*) their intrinsic ability to self-assemble into filaments and also (*ii*) their rod-like shape with the length of about 500 Å. We overcome these obstacles by examining a series of overlapping vimentin fragments, with the ultimate goal of resolving the complete molecule. This information is crucial for establishing the process of the IF assembly.

The predominant central part of vimentin is predicted to be a double-stranded α-helical coiled coil. Our experience suggests that coiled coils up to about 100 Å in length can often be crystallised while longer ones have a tendency for nonspecific aggregation [3]. Z2B is a soluble fusion protein containing 31 residues of the GCN4 leucine zipper [4] followed by residues 385 to 412 of human vimentin. We have obtained crystals of Z2B and collected diffraction data to 1.9 Å resolution. Molecular replacement with the known structure of the GCN4 zipper yielded three solutions corresponding to the same noncrystallographic dimer but differing by 7-residue register shifts. The final model (crystallographic R=0.20, R_{free}=0.24) contains a continuous coiled coil starting at the N-terminus and ending with residue 405 of vimentin. A number of other soluble vimentin fragments, including those representing the central coiled coil region as well as the N- and C-terminal globular domains, is currently being subjected to crystallisation and preliminary X-ray analysis.

P06.04.069 STRUCTURE OF PHOSPHPLIPIDS IN A MEMBRANE PROTEIN COMPLEX, BOVINE HEART CYTOCHROME C OXIDASE. T.Mizushima*, M.Yao*, N.Inoue*, H.Aoyama*, E.Yamashita*, H.Yamaguchi*, T.Tsukihara*, R.Nakashima[#], K.Shinzawa-Itoh[#], R.Yaono[#], S.Yoshikawa[#], * Institute for Protein Research, Osaka University, 3-2 Yamada-oka, Suita 565-0871, Japan. [#] Department of Life Science, Himeji Institute of Technology, Kamigohri Akoh, Hyogo 678-1297, Japan.

Cytochrome *c* oxidase is a membrane protein complex, existing in the mitochondrial inner membrane. This enzyme is composed of two monomers, each containing thirteen different subunits. Purified cytochrome *c* oxidase usually contains several phospholipids. They are cardiolipin (CL), phosphatidylcholine (PC), phosphatidylethanolamine (PE), and phosphatidylglycerol (PG). Cardiolipins are essential for maximal activity of the enzyme complex and can not be replaced by other phospholipids without loosing the activity. However the binding sites and functions of the phospholipids are still unknown.

The crystal structure of bovine heart cytochrome c oxidase at 2.8Å resolution has located eight phospholipids in the enzyme molecule. Then X-ray analysis at the higher resolution of 2.3 Å elucidated 14 phospholipids, three CL, one PC, three PE and seven PG, were in the monomer. All phospholipids were found in the transmembrane region, five of them were at intermembrane side, and the other nine were at matrix side. One CL, two PE, and one PG were placed in the intermonomer space. Especially the CL played assistant role to make the dimeric structure. One PE and two PG were located in the large cleft of subunit III. This cleft seemed a pool of oxygen molecule. Dioxygen molecules could approach to the dioxygen reduction site from the pool in the subunit III which was likely to keep the hydrophobic dioxygen molecules. These phospholipids were bound to the protein by salt bridges or hydrogen bonds between the polar head groups and amino acid, and also by the hydrophobic interaction between the fatty acids and the hydrophobic amino acid residues in the transmembrane region. Each phospholipid joined protein subunits together to form the enzyme complex.

P06.04.070 STRUCTURAL EXAMINATION OF THE LAST METAL-ION COORDINATING RESIDUE IN A PARVALBUMIN EF-HAND SITE. M. Susan Cates [1], Emai L. Ho [2], Michael B. Berry [3], Qi Li [4], James D. Potter [5], George N.Phillips, Jr. [6], [1] Dept. of Biochemistry and Cell Biology, Rice University, Houston, TX, 77005-1892, [2] Dept. of Biochemistry and Cell Biology, Rice University, Houston, TX, 77005-1892, [3] Dept. of Biochemistry and Cell Biology, Rice University, Houston, TX, 77005-1892, [4] Dept. of Molecular & Cellular Pharmacology, University of Miami School of Medicine, Miami, FL, 33136, [5] Dept. of Molecular & Cellular Pharmacology, University of Miami School of Medicine, Miami, FL, 33136, [6] Dept. of Biochemistry and Cell Biology, Rice University, Houston, TX, 77005-1892

Parvalbumin mutants have been created to examine the effect of individual EF-hand domain residues on Ca2+-binding. The PVEF parent mutant contains a conservative F102W mutation, plus a D51A mutation which inactivates one of the protein's two Ca2+-binding sites at physiological levels of Ca2+. Structural comparison to the wild type EF site shows that the

D51A mutation does not effect Ca2+ coordination by the active EF site. Ca2+-binding parameters for the active site of PVEF also show wild type behavior.

The PVEF-E101D mutant has the PVEF mutations plus an E101D mutation in the functional EF-hand. Residue 101 is the last coordinating residue in the second EF-hand binding site. Crystal structures have been obtained of both PVEF-E101D bound to Ca2+ and PVEF-E101D bound to Mg2+. The conformation of the mutated EF-hand in Mg2+/PVEF-E101D is typical of a Mg2+/EF-hand, with the exception of some F helix rearrangement to accommodate the shorter ASP. The Ca2+/PVEF-E101D structure shows that the ASP residue is unable to bind Ca2+ in the bidentate mode adopted by the wild type GLU. The resulting 6-fold Ca2+ coordination in the mutant is usually characteristic of Mg2+. Moreover, PVEF-E101D shows only a 10-fold greater preference for Ca2+ over Mg2+, while wild type has a 10,000-fold preference for Ca2+-binding.

P06.04.071 CRYSTAL STRUCTURE OF 40KDA CALCIUM-BINDING PROTEIN (CBP40) SPECIFIC TO PLASMODIA OF P. POLYCEPHALUM. W. Iwasaki [1], H. Sasaki [2], A. Nakamura, K. Kohama [3], M. Tanokura [1], [1] Department of Applied Biological Chemistry, Graduate School of Agricultural and Life Sciences, University of Tokyo, Yayoi 1-1-1, Bunkyo-ku, Tokyo 113-8657, Japan, [2] Biotechnology Research Centre, University of Tokyo, Yayoi 1-1-1, Bunkyo-ku, Tokyo 113-8657, Japan, [3] Department of Pharmacology, Gunma University, School of Medicine, Maebashi, Gunma 371, Japan.

A calcium binding protein with the molecular mass of 40kDa (CBP40) was purified from the lower eukaryote Physarum polycephalum by Kohama et al. The cDNA of CBP40 was identical with cDNA named LAV1 which had been cloned from a plasmodial-specific mRNA of P. polycephalum by Pallotta et al. CBP40 consists of 355 amino acids and contains four EF-hand domains in its C-terminal half region. The function of CBP40 remains unknown. In order to know the function of CBP40, we determined the crystal structure at 3.0Å resolution. Recombinant CBP40 expressed in E.coli was purified and crystallized in the presence of EDTA. The crystals belonged to the trigonal space group $P322_1$ with a=b=64.39Å and c=207.22Å. The crystals diffracted X-rays to resolution of 3.0Å at room temperature and 2.7Å at 100K. The crystals of calcium-binding form were obtained by soaking into a CaCl2 solution, which gave diffraction data of similar quality. The structure was determined by multiple isomorphous replacement method using two heavy atom derivatives of Hg and Sm. The refined model at 3.0Å resolution has an R-value 22.6%. The final model at higher resolution (2.7Å) will be obtained by the molecular replacement method using the model of 3.0Å. The structure is very rich in a-helices and its topology shows the notable feature, which provides insights about function of CBP40 and evolution of the EF-hand family.

P06.04.072 STRUCTURE OF AN XRCC1 BRCT DOMAIN: A NEW PROTEIN PROTEIN INTERACTION MODULE. Xiaodong Zhang†, Solange Moréra†, Paul A. Bates^, Philip C. Whitehead§, Arnold I. Coffer§, Karl Hainbucher†, Rachel A. Nash‖, Michael J. E. Sternberg^,Tomas Lindahl‖ and Paul S. Freemont† Molecular Structure and Function, ^Biomolecular Modelling, §Protein Isolation and Cloning and ‖Mutagenesis Laboratories, Imperial Cancer Research Fund 44 Lincoln's Inn Fields London WC2A 3PX, UK ‖ICRF Clare Hall Laboratories South Mimms Herts EN6 3LD, UK

The BRCT domain (BRCA1 C-Terminus), first identified in the breast cancer suppressor protein BRCA1, is an evolutionarily conserved protein-protein interaction region of about 95 amino acids found in a large number of proteins involved in DNA repair, recombination, and cell cycle control. We report the first three-dimensional structure and fold of a BRCT domain determined by X-ray crystallography at 3.2Å resolution. The structure has been obtained from the C-terminal region of the human DNA repair protein XRCC1. It comprises a four-stranded parallel β–sheet surrounded by three α-helices, which form an autonomously folded domain. The compact XRCC1 structure explains the observed sequence homology between different BRCT motifs and provides a framework for modelling other BRCT domains. Furthermore, the established structure of an XRCC1 BRCT homodimer suggests potential protein-protein interaction sites for the complementary BRCT domain in DNA ligase III, since these two domains form a stable heterodimeric complex. Based on the XRCC1 BRCT structure, we have constructed a model for the C-terminal BRCT domain of BRCA1, which is frequently mutated in familial breast and ovarian cancer. The model allows insights into the effects of such mutations on the fold of the BRCT domain.

P06.04.073 THE ARCHITECTURE OF FLAVO-ENZYMES ON THE BASIS OF THE TERTIARY STRUCTURE OF YEAST LIPOAMIDE DEHYDROG-ENASE. T. Toyoda† and A. Takenaka, Faculty of Bioscience and Biotechnology, Tokyo Institute of Technology, Yokohama, Japan; † Present institution: Institute of Medical Science, University of Tokyo, Tokyo, Japan; and T. Sekiguchi, Faculty of Science and Engineering, Iwaki Meisei University, Fukushima, Japan.

Lipoamide dehydrogenase (E3), which is the common component in 2-oxo acid dehydrogenase complexes, is classified as a member of the pyridine nucleotide-disulfide oxidoreductase family. The x-ray structure of yeast E3 has been solved at 2.7Å resolution (R=20.2%, Rfree=26.2%) and compared with those of the other four proteins, trypanothione reductase, glutathione reductase, NADH peroxydase, and thioredoxin reductase, in the same family. E3 is a homo dimeric enzyme similar to the former three proteins, so that the subunits consist of four domains (FAD, NADH, central, and interface domains). The FAD and the NADH domains are composed of a similar topology of their secondary structures containing a Rossmann fold essential for the catalytic reactions. Although the amino acid sequence identities are rather lower among them, the central and the interface domains are also similar in the secondary structural topology. Differences occur only near the substrate binding pockets. In thioredoxin reductase, however, the latter two domains are missing. These facts suggest that proteins in the family are evolved from the common ancestor to catalyze the similar reaction, oxidation/reduction of a disulfide bond with electron transfer through NAD(P)H and FAD. The p64k protein in the family has an additional domain. Therefore it is noted at the present that there are at least three subclasses in the architectures of this family depending on the number of domains.

P06.04.074 VARIATIONS ON THE JELLY-ROLL THEME. I.J Clifton, L-C Hsueh, Z-H Zhang, C.J Schofield, Oxford Centre for Molecular Sciences, Dyson Perrins Laboratory, Oxford OX1 3QY, UK, and K. Harlos, Laboratory of Molecular Biophysics, Rex Richards Building, Oxford OX1 3QU, UK.

The crystal structures of several 2-oxoglutarate dependent oxygenases have now been determined. The structures of

isopenicillin *N* synthase [1] and deacetoxycephalosporin *C* synthase [2] have already been published. The new structures of two further representatives of this family, proline 3-hydroxylase (type II) and clavulanic acid synthase, are described and compared to those earlier structures.

All these non-haem iron-containing enzymes share a common architecture based on a central jelly-roll barrel. This eight-stranded β barrel with simple winding topology is found in many protein structures, however this family of proteins seems to use the jelly-roll barrel in an unusual way, as a housing for an iron atom. The iron is held on one interior surface of the barrel, like a pearl in an oyster. Ligands from the enclosing surfaces form the binding sites for the substrates. The range of structures we now have allow us to speculate about the biochemical repertoire of this simple and versatile jelly-roll-iron architecture. They also have implications for the evolution of the family of 2-oxoglutarate dependent oxygenases and allow detailed mechanisms to be proposed.

P06.04.075 STRUCTURE OF LEFT-HANDED β-HELICAL ACETYLTRANSFERASES. Naveen Chandra (1), Jaruwaree Snidwongse (2), Iain A. Murray (2) and Peter C. E. Moody (1), 1) Department of Biochemistry, University of Leicester, Leicester LE1 7RH, UK, 2) Department of Molecular Biology and Biotechnology, University of Sheffield S10 2TN UK

XAT (Xenobiotic Acetyltransferase) from Agrobacterium SAT (Serine Acetyl transferase from E.coli and Nodl from Rizobium leguminosarum are members of the recently discovered family of trimeric left-handed parallel β-helical CoA O-acetyl transferases. Although they share a common core and acetyl donor, there is a wide variety of acceptor substrates. We are studying the structures of these enzymes with the aim of discovering the way in which the common structural core can accommodate such a diversity of specificities.

We have refined the structure of apo-XAT to 1.5Å and the acetyl-CoA derivative to 2.0Å. We will describe these structures and the crystallographic evidence that SAT and Nodl also belong to this family will be shown. Progress in the determination of the structures of SAT and Nodl will be reported.

P06.04.076 THREE-DIMENSIONAL STRUCTURE OF 2-DEHYDRO-3-DEOXYGLUCARATE (DDG) ALDOLASE FROM ESCHERICHIA COLI. Tina Izard, Nic Blackwell & Ron A Cooper, Department of Biochemistry, University of Leicester, LE1 7RH, UK

2-dehydro-3-deoxyglucarate (DDG) aldolase (EC 4.1.2.20) catalyses the reversible aldol cleavage of 2-dehydro-3-deoxy galactarate or 2-dehydro-3-deoxy glucarate to pyruvate and tartronic semialdehyde. The aldol condensation is an important reaction in synthetic chemistry, although the more complicated the desired product, the less efficient the reaction due to poor control over stereochemistry. Aldolases carry out specific condensations with exquisite control on the stereochemistry. In addition, because aldolases can be regulated depending on the concentrations of reactants and products, these enzymes are attractive as catalysts for synthetic chemistry. Aldolases catalyse a variety of aldol condensation or cleavage reactions and are mechanistically divided into two classes. The class I aldolases use an active-site lysine residue in Schiff base formation with substrate whilst the class II enzymes require a metal cofactor. DDG aldolase belongs to class II enzymes. DDG aldolase from Escherichia coli has been overexpressed, purified and crystallised. The DDG aldolase crystals belong to the space group R32 with unit cell dimensions a = b = 125 , c = 175 Å, γ = 120°. Here we present the three-dimensional structure of DDG aldolase and some insights into its mechanism of reaction.

P06.04.078 STRUCTURE OF RABBIT HAEMOPEXIN AT 2.1Å. B.F.Anderson, Institute of Molecular Biosciences, Massey University, Palmerston North, New Zealand. H.M.Baker and E.N.Baker, Laboratory for Structural Biology, University of Auckland, Auckland, New Zealand. M.Paoli, Department of Biochemistry, University of Cambridge, Cambridge, England.

Haemopexin is a mamalian, serum glycoprotein that sequesters free haem with high affinity from the bloodstream and only releases it upon interaction with a specific receptor on the surface of liver cells where it is internalised(1,2). The molecule is thus a haem scavenger and so acts to protect the organism from free-haem oxidative damage as well as conserving and recycling this important prosthetic molecule. The deglycosylated protein has been solved at lower resolution and shown to contain two 4 bladed propellor domains(3). Native, fully glycosylated, rabbit haemopexin complexed with haem crystallises in spacegroup P4, a=b=139.39, c=51.13Å.The crystals diffract to 2.1Å and contain two molecules in the asymmetric unit. The structure was solved by molecular replacement using as a search model the N an C domains taken from the lower resolution deglycosylated structure solved previously(3). AmoRe gave no useable results in spacegroup P4 but four of the expected 8 domains were located in a low resolution data set processed as monoclinic. The remaining domains were positioned by modelling. L.S refinement gives current working and free Rfactors of 0.31 and 0.35 respectively for all P4, 30.0-2.1Å data. Each molecule comprises two structurally homologous, 4 bladed propellor domains with the haem bound, through histidine residues, between them. An unusual feature is that the haem is bound with the propionates partially buried while the opposing methyl and alkyl groups point toward the solvent.

P06.04.079 CRYSTALLOGRAPHIC STUDIES OF THE NADP-DEPENDENT β-KETO ACP REDUCTASE FROM *ESCHERICHIA COLI*. Martin Fisher,[1] Wayne Martindale,[2] Antoni R. Slabas,[2] David W. Rice[1] and John B. Rafferty[1]. [1]Krebs Institute for Biomolecular Research, Department of Molecular Biology and Biotechnology, The University of Sheffield, Sheffield, S10 2TN, UK, and [2]Lipid Molecular Biology Group, Department of Biological Sciences, The University of Durham, Durham, DH1 3LE, UK.

Fatty acid biosynthesis is a critical metabolic function which provides both cellular building materials and energy storage reserves. It is catalysed by a complex enzyme pathway, the fatty acid synthetase system (FAS). This can be classified into two types based upon whether the enzymes which catalyse the individual steps in the pathway reside as catalytic sub-domains on one or two multifunctional polypeptides (Type I) or are located on separate polypeptide chains (Type II). A Type II FAS is found in plants and many bacteria, including *E.coli*, where there are six successive steps in the elongation of the fatty acid chain. Each step involves carboxylation, transacylation, condensation, reduction, dehydration and a further reduction of the incoming substrate with the resultant incorporation of a two-carbon unit into the growing chain. The first reductive step is catalysed by an NAD(P)- dependent β-keto acyl carrier protein reductase (BKR)

which reduces the keto group of a β-keto acyl ACP substrate to its hydroxy product.

The *E.coli* BKR has been crystallized by the hanging-drop method of vapour diffusion using polyethylene glycol of average molecular weight 1450 Da. The crystal belongs to the hexagonal space group $P6_122$ with unit-cell dimensions of a=b=68 and c=359 Å. Crystal packing analysis confirms that the asymmetric unit contains a dimer, where each monomer has a molecular weight of 28kDa. Crystals were mounted in capillary tubes and a data set was collected by the rotation method with 2° rotations per frame at an X-ray wavelength of 0.872Å on station 9.6 at the Synchrotron Radiation Source (SRS), Daresbury Laboratory, using a large MAR image plate. The crystals have been shown to diffract to better than 2.5Å resolution. Molecular replacement studies, coupled with isomorphous replacement data from a cysteine mutant and a selenomethionine incorporated protein, have given us an interpretable 2.5 Å map showing the orientation of the protein within the unit cell and by using the least-squares molecular refinement program, TNT, a model of BKR has successfully been built and refined. The structure is reminiscent of a typical Rossmann fold and as predicted resembles that of enoyl ACP reductase, the enzyme which catalyses the other reductive step in the FAS cycle.

We have recently obtained a crystal which contains the NADPH cofactor within the nucleotide-binding site of BKR and data have been collected to 2.5Å resolution on station 9.6 at the SRS. Refinement of the data is currently in progress.

P06.04.080 SEQUENCE DEPENDENCE OF CONFORMATION AND SUPERMOLECULAR STRUCTURE IN COLLAGEN-LIKE PEPTIDES. Rachel Z. Kramer[1], Jordi Bella[1,2], Luigi Vitagliano[3], Manju Venugopal[4], Patricia Mayville[1], Barbara Brodsky[4] and Helen M. Berman[1]. [1]Department of Chemistry, Rutgers University, Piscataway NJ 08855, [2]Present address: Department of Biological Sciences, Purdue University, West Lafayette IN 47907, [3]Centro di Studio di Biocristallografia, CNR and Dipartimento di Chimica, Universita' di Napoli, 80134 Napoli Italy, [4]Department of Biochemistry, University of Medicine and Dentistry of New Jersey, Piscataway NJ 08855.

We have determined the structures of three homotrimeric collagen-like peptides. These studies demonstrate a strong synergy among sequence, hydration, and supermolecular structure and provide the first visualization of how the sequence of collagen defines local variations in triple-helical conformation. The crystal structure of $(PPG)_{10}$ [1] demonstrates that the involvement of hydroxyproline in an extended hydration network is critical for the lateral assembly and supermolecular structure of collagen. The structure of $(POG)_4EKG(POG)_5$ [2] displays an axial staggering among molecules, reminiscent of that observed in D-periodic collagen fibrils and demonstrates the sequence dependence of axial packing. $(POG)_3ITGARGLAGPOG(POG)_3$ was designed to model the region of human type III collagen C-terminal to the collagenase cleavage site. The structure of this peptide [3] displays variable triple-helical symmetry along the molecule, demonstrating the sequence dependence of molecular conformation.

P06.04.081 A TRIMER-OF-HAIRPINS AS A DOMINANT MOTIF IN VIRAL MEMBRANE-FUSION PROTEINS. V.N. Malashkevich and P.S. Kim, Whitehead Institute, Howard Hughes Medical Institute, Department of Biology, MIT, Nine Cambridge Center, Cambridge, MA 02142, USA

High-resolution crystal structures of cores of the transmembrane subunits (TM) from the envelope glycoproteins of human and simian immunodefficiency viruses (HIV-1 and SIV), Visna and Ebola viruses, reveal a trimer of α–helical hairpins as a common motif. Each polypeptide chain in the trimer folds into a helical-hairpin conformation, in which two antiparallel helices are connected by a loop region. The N-terminal helices from each monomer form a central, three-stranded coiled coil that is positioned to support the hydrophobic "fusion-peptide" region of the protein. C-terminal helices pack in an antiparallel manner into hydrophobic grooves on the surface of this coiled-coil core. The abundance and structural conservation of this trimer-of-hairpins motif within the families of retroviruses, filoviruses, paramyxoviruses, and orthomyxoviruses, lacking any sequence homology within their envelope glycoprotein domains, suggests that this motif is critical for the fusion between viral and host cell membranes. This structural motif presumably corresponds to the fusion-active state, distinct from the native (non-fusogenic) state. In each case the N-terminal region of the protein, which contains the fusion peptide, is brought close to the C-terminal region, which connects to the transmembrane helix of the protein. Thus, given that the fusion peptide inserts into the cell membrane and the transmembrane helix is anchored in the viral membrane, the likely role of the hairpin structure is to facilitate the apposition of the viral and cellular membranes. These structures may assist in the discovery of a new class of agents that prevent viral infection. Indeed, synthetic peptides corresponding to the C-terminal helices of the trimer-of-hairpin structures in HIV-1 or in paramyxoviruses are inhibitors of entry by those viruses.

P06.04.082 THE REFINED CRYSTAL STRUCTURE OF THE AUGMENTER OF LIVER REGENERATION. John P. Rose[1], Chia-Kuei Wu[1,2], Tamara A. Dailey[1], Harry A. Dailey[1], and Bi-Cheng Wang[1], Department of Biochemistry and Molecular Biology University of Georgia, Athens GA 30602, U.S.A. and [2]Department of Crystallography, University of Pittsburgh, Pittsburgh PA 15260 U.S.A

The extraordinary regenerative capacity of the mammalian liver known since mythological times has been the focus of study for more than a century. The structure of a cytosolic factor first described by MoJunkin and Breuhaus in 1931 now termed augmenter of liver regeneration (ALR) has been determined at 2.5 Å resolution. ALR is associated with increased hepatocyte replication in the liver of weanling rats and in the regenerating adult liver remnant after partial hepatectomy. This factor has recently been shown to significantly enhance the success rate of fetal pancreatic islet transplantation in rodents and may prove to be useful for other purposes.

Sequence analysis shows that ALR has a unique sequence but shares a 50% homology with the product of the dual-function gene ERV1 of *Saccharomyces cerevisiae*. The ALR sequence predicts an all-alpha structure with little beta sheet. An incomplete Zn-finger like binding motif is also suggested.

Biochemical studies show that ALR contains bound Zn and FAD. This is intriguing since the ALR sequence showed no recognizable dinucleotide-binding motif. Thus, ALR may exhibit a new mode of dinucleotide binding.

The crystal structure revealed that ALR is an all-alpha cone shaped four-helix bundle. The flavin ring of the bound FAD sits in the mouth of the cone while its adenosine tail lies in a grove between the N-terminal and C-terminal helices. Details of the structure and structure analysis will be presented.

Work supported by the Georgia Research Alliance and The University of Georgia.

P06.04.083 CRYSTALLOGRAPHIC STUDIES ON β-LACTOGLOBULIN L.Sawyer, S.-Y.Wu and G.Kontopidis, Structural Biochemistry Group, ICMB, The University of Edinburgh, Swann Building, Mayfield Road, Edinburgh EH9 3JR, UK and D.M.Pérez & P.Puyol, Food Technology, Veterinary Faculty, University of Zaragoza, 50013 Zaragoza, Spain.

The milk whey protein β-lactoglobulin (BLG) from ruminants is a dimer of M_r 36,000 with two polypeptide chains of 162 residues. There are 2 cystines and a cysteine. Genetic variants exist and the protein, which is an archetypal lipocalin, is present in many, but not all, mammalian species.

The behaviour of BLG has been shown to be important to the processing properties of milk and in particular the pH and temperature dependence of the aggregation that occurs above 60°C appears to involve a disulphide interchange mechanism. The effects of heat treatment are modified by the presence of ligands both attached to the free –SH group and also bound to an internal cavity. The structures of 3 crystal forms of the free protein and the protein with bound ligands have been determined both in Edinburgh and elsewhere. These structural results together with the latest ligand-binding data will be discussed in the light of the large amount of solution data that have accumulated over the past 60 years.

We are grateful to an EU Concerted Action (MADGELAS) and the BBSRC for financial support.

P06.04.084 PECTIN METHYLESTERASE IS A PARALLEL β-HELIX PROTEIN WITH TWO CATALYTIC ASPARTATES. John Jenkins[1], Drummond Smith[1], Kathryn Worboys[1], Olga Mayans[2] and Richard Pickersgill[1], [1]Institute of Food Research, Whiteknights Road, Reading RG6 6BZ, UK, [2] EMBL, Notkestrasse 85, D-22603, Hamburg, Germany

Pectin methylesterase is one of the four types of enzyme involved in degrading the homogalacturanon backbone of pectin together with pectate lyase, pectin lyase and polygalacturonase and has an important role in plant growth, fruit ripening and in microbial pathogenesis. The sequences of pectin methylesterases are not obviously homologous to any protein with a known 3-dimensional structure.

Pectin methylesterase from *Erwinia chrysanthemi* has been expressed, purified and crystallized from 2 M ammonium sulfate at pH 6.8 with two 342 amino acid molecules in the asymmetric unit of the $P2_1$ unit cell. Addition of 25% glycerol allows data to be collected at 100 K. Three heavy atom datasets were used for phasing with an overall figure of merit of 0.48. The phases were improved and extended to 2.4Å resolution using the program DM.

The averaged map revealed a right handed parallel β-helix architecture which suggested distant homology with the pectic lyases and polygalacturonase and allows the nomenclature of PB1, T1, PB2, T2, PB3 and T3 to be used. The active site (by homology and sequence conservation) lies on PB1 in a cleft formed by N-terminal T3 and C-terminal T1 loops. Two aspartates, D178 and D199, are on neighbouring coils of the parallel β-helix. They are surrounded by many aromatic residues suggesting an analogy to the active site of pectin lyase although none are conserved. The two aspartates suggest a similar mechanism to that of the aspartyl proteases. Thus pectin methylesterase shows striking examples of both convergent and divergent evolution. The current model has a free R value of 24.78% and a working R value of 20.19% with 402 water molecules.

P06.04.085 STRUCTURAL ANALYSIS OF ALLERGENS: CRYSTAL STRUCTURE OF HEV B 6.02 (HEVEIN) AT 1.5 Å RESOLUTION. A. Rodríguez-Romero, P. Llinas, A. Hernandez-Santoyo, Instituto de Química, Universidad Nacional Autónoma de México, Circuito Exterior, Ciudad Universitaria, Coyoacán 04510. Mexico, D:F.

Hypersensitivity reactions to natural rubber latex (NRL) proteins have been increasingly recognized during the past two decades. It is well documented that a high percentage of health care workers and patients who have undergone multiple operations are allergic to NRL and manufactured NRL products such as gloves, catheters, condoms, etc. Different studies have revealed various antigenic proteins with Mr from 5 to 200 KDa in latex preparations, and some of them have already been identified. Prohevein (Hev B 6.01) and hevein (Hev b 6.02) have been shown to be major IgE-binding allergens and in the former the principal epitopes have been located in its N-terminal hevein domain. Recently, substantial progress has been made in the purification and molecular characterization of several NRL allergens that has facilitated the assessment of their significance and given grounds for proper comparison of results obtained by different researchers. However, information on the tertiary structure of allergens is limited; just a few structures of airborne allergens and one contact allergen have been reported1. The knowledge of the structure of these proteins will make it simpler to identify and change surface epitopes, thus improving immunotherapy.

We report here the structure of Hev B 6.02 (hevein) at 1.5 Å resolution. The protein was crystallized from MPD in space group $P2_12_12$ with cell parameters a=31.81 Å, b=58.93 Å and c= 22.51 Å. Complete data set was collected at SSRL beamline 7-1 with an overall R-merge of 5.0 %. The structure was solved using molecular replacement with AmoRe (Navaza, 1994) and refined using CNS (Brunger, 1998). Details of the structure and a comparison with other allergens will be presented. Finally, we have found that hevein binds to neutrophiles.

This work was supported by DGAPA, UNAM grant IN-201997.

P06.04.086 X-RAY STRUCTURE ANALYSES OF MUTANT REACTION CENTRES AFFECTING PROTON TRANSFER AND QUINONE BINDING. A. Kuglstatter, G. Fritzsch, H. Michel [1], L. Baciou [2], [1] MPI fuer Biophysik, Abt. Molekulare Membranbiologie, 60528 Frankfurt/M, Germany, [2] Centre de Genetique Moleculaire, CNRS, 91198 Gif-sur-Yvette, France

The structures of three mutant reaction centres from the photosynthetic purple bacterium Rb. sphaeroides have been determined by X-ray crystallography to 2.6-2.8 Å resolution. The mutants have been constructed to interrupt a chain of tightly bound water molecules that is assumed to be involved in proton transfer from the cytoplasm to the secondary quinone (QB) [1,2]. The mutations Pro L209 -> Tyr and Pro L209 -> Phe do not disturb the chain. Instead, these residues take up a conformation in which three surrounding side chains are displaced. The position of QB is shifted compared to the wild-type protein. In the Pro L209 -> Glu mutant the introduced residue is located within the water chain and the binding site of QB is unchanged.

P06.04.087 NEUTRON PROTEIN CRYSTALLOGRAPHY REVEALS HYDROGEN BONDING AND BOUND WATER STRUCTURE Y. Minezaki, N. Niimura, Advanced Science Research Center, Japan Atomic Energy Research Institute, Tokai-mura, Ibaraki, 319-1195, JAPAN

X-ray protein crystallography is a powerful tool for structural biology and it has helped to shed light on many important processes in life. But many fundamental principles are still poorly understood because of the lack of structural information on hydrogen, which constitutes half of the atoms in protein molecules. In principle, it is very difficult to get information of hydrogen positions by X-rays. In contrast, neutron protein crystallography has a great potential for investigating the complete structure of a protein, including the positions of the hydrogen atoms. However, only a few experiments have been reported to date since it takes an enormous amount of experimetal time to collect data, eg. about several months. Recently we have shown that the whole data set of hen egg-white lysozyme could be collected in only 10 experimental days by using neutron imaging plates coupled with the neutron quasi-Laue method. All of the 960 hydrogen atoms in the lysozyme molecule and in 157 bound water molecules could be identified. We have proceeded further with this analysis and have focused on the hydrogen bonding patterns and the water structure in more detail.

We have investigated the nature of intramolecular backbone hydrogen bonds of "N-H…O" type, which play an important role in the stabilization of the secondary structure of proteins. The distance distribution of H bonds can be divided into two categories, one of which is assigned to the alpha-helix and beta-strand regions, and another of which is assigned to loop region.

We have found that other types of hydrogen bonds exist besides the normal single (X-H…Y) hydrogen bond. They are the bifurcated (double) and trifurcated (triple) hydrogen bonds. Since many acceptors and donors exist close each other in a globular protein, the possibility of forming bifurcated and trifurcated hydrogen bonds is higher than usual. Our statistical analysis supports this conclusion. Even in the alpha-helix and beta-sheet regions, many bifurcated hydrogen bonds were found. We have categorized these types of bonds into several groups.

Another unusual hydrogen bond we have found is the aromatic hydrogen bond, which involves an interaction between the pi-electron cloud of an aromatic ring and a hydrogen-bond donor. One water molecule was found associated with the indole pi-ring of Try62, while another one was found near that of Try123.

The authors are grateful to prof. R. Bau for critical discussion.

P06.04.088 SYNCHROTRON SAXS STUDY OF THE STRUCTURAL CHANGES CAUSED BY SOLVENTS IN POLY-URETHANE MEMBRANES. H.Grigoriew[1], A.Wolińska-Grabczyk[2], A.G.Chmielewski[1], J.Domagała[3] [1]Institute of Nuclear Chemistry and Technology, Dorodna 16. 03195 Warsaw, Pl, [2]Institute of Coal Chemistry PAS, Sowińskiego 5, 44102 Gliwice, Pl, [3]Institute of Physics PAS Al.Lotników 32/46, 02668 Warsaw, Pl

When poly-urethanes composed of hard and soft segments of various length were swelled by solvents, we found: i. for shorter soft segments - ordering of hard domains which size depends on the hard segment length, ii. for longer soft segments - no ordering but only more dispersed structure.

Segmented polyurethanes are regarded as multiblock copolymers of $(AB)_n$ type in which A and B are the hard- and the soft-segment repeat units. The polyurethanes studied are composed of poly(tetramethylene oxide)-based soft segments and hard segments composed of 2,4-tolylene diisocyanate (TDI) chain extended with 4,4-diphenylmetane diamine (PP). The structural variations of composition within the series studied come from the different molar masses of the soft-segments (2000 or 1000) and/or different length of the hard-segments (TDI PP or 3(TDI PP) sequences).

SAXS experiment was performed on A2 beamline at HASYLAB-DESY using time-resolved mode, with raising temperature from room to 70^{o}C and then cooling. The dry membranes and membranes saturated with benzene and with ethanol were measured. The following changes were obtained on SAXS curves for subsequent materials: i. TDI PP/1000 -an intense, broad maximum of 17nm, which decreases with raising of temperature, ii. 3(TDI PP)/1000 -position of the maximum is 22nm, iii. TDI PP/2000 -no maximum, R_g decreases from 15nm for dry to 9nm for swelled membrane.

The effects are similar for both solvents but more intense for benzene.

P06.04.089 DO WATER-PROTEIN HYDROGEN BONDS COMPENSATE FOR INTERACTIONS IN THE STREPTAVIDIN-BIOTIN COMPLEX? R.E. Stenkamp [1,2], S. Freitag [2,3], I. Le Trong [1,2], L.A. Klumb [3], V.Chu [3], D. Hyre [3], J.E. Penzotti [3], R. To [3], T.P. Lybrand [3] and P.S.Stayton [3]; [1] Dept. of Biological Structure, Univ. of Washington, Seattle, WA 98195, [2] Biomolecular Structure Center, Univ. of Washington, Seattle, WA 98195 [3] Dept. of Bioengineering, Univ. of Washington, Seattle, WA 98195

The hydrogen bonds between water and unliganded streptavidin differ significantly from those formed in the protein/biotin complex. Both the pattern and structure of the hydrogen bonds change when biotin binds to the protein. This might explain the large enthalpic contribution to the high free energy of binding. Comparison of several high resolution ligand-free crystal structures improves our model of the number and location of water molecules in the biotin binding site. Preliminary examination of the superposed structures show that water molecules do not simply replace the hydrogen-bond acceptor and donor atoms in the biotin complex. The polar ureido oxygen atom of biotin accepts three hydrogen-bonds in its interactions with streptavidin. A water molecule can accept two hydrogen- bonds and thus can not completely substitute for the ureido oxygen. Also, the covalent structure of biotin, particularly the ureido group, sterically restrains the locations of its hydrogen-bond donors and acceptors. Van der Waals contacts between individual water molecules preclude their occupation of the same positions as the ureido oxygen and nitrogen atoms. The superposed water molecules cluster near the positions of the ureido nitrogen atoms, but slightly displaced from them. This leads to a spatial difference in the hydrogen-bonds in the unliganded and liganded structures which can account for part of the binding free energy. A recent atomic resolution structure of one of the mutants shows that MPD from the crystallization solution binds loosely to the biotin binding site. The possible effect of this on our models for the unliganded structures will be discussed. This work is supported by NIH grant DK-49655.

P06.04.090 CRYSTAL STRUCTURE ANALYSIS OF CONGER EEL GALECTINS. T. Shirai, C. Mitsuyama, Y. Niwa, Y. Matsui, H. Hotta, T. Yamane, T. Ogawa and K. Muramoto, Department of Biotechnology and Biomaterial Chemistry, Graduate School of Engineering, Nagoya University, Nagoya 464-8603, Japan, and Department of Biological Resource Science, Graduate School of Agricultural Science, Tohoku University, Sendai 981-8555, Japan.

Congerins are members of galectin family, animal β-galactoside-binding S-type lectins, from conger eel (*Conger myriaster*). Congerin is a homodimer of 14 kDa subunit. Having one carbohydrate-binding site on one subunit, the dimer has two carbohydrate-binding sites that enable the dimer to cross link molecules or cells that have bl-galactoside-moieties. Congerins show the activity in aggregating murine bacteria implying a biological defense function of the protein. We have crystallized congerin I in ligand-free and lactose-liganded forms. The both crystals are isomorphic each other, and belong to orthorhombic space group $P2_12_12$. The asymmetric unit contains one monomer, two fold axis of the dimer overlaps to the crystallographic two fold axis. Full data sets to resolution of 1.5 A and 1.6 A for lactose-liganded and ligand-free form crystals, respectively, were collected using the synchrotrons X-ray source from Photon Factory, National Laboratory for High Energy Physics. The crystal structures were determined using molecular replacement method. Bovine galectin was used as a search model.

A comparison of the carbohydrate-binding sites in both forms shows that the structures around the sites are nearly identical. Exceptionally, a loop that conforms a part of the binding-site moves 0.5-0.9 A between the free and liganded forms. The lactose in the binding site forms eleven hydrogen-bonds directly with protein atoms. In the ligand-free form, nine of the eleven hydrogen-bonds are formed between water molecules and the protein atoms. The water molecules in the free-binding site occupy the space for oxygen atoms of lactose in liganded-form. This observation implies carbohydrate-binding of congerin is entropy-driven process.

P06.04.091 STRUCTURE DETERMINATION OF APOE3 IN THREE SPACEGROUPS BY MAD OR MOLECULAR REPLACEMENT TECHNIQUES. Michael Forstner [1], Brent Segelke [1], Bernhard Rupp [1] Yvonne Newhouse [2], Karl Weisgraber [2], [1] Biomolecular Crystallography Facility, Lawrence Livermore National Laboratory, Livermore, CA 94551, USA, [2] Gladstone Institute for Cardiovascular Disease, University of California San Francisco, San Francisco, CA 94141, USA

Apolipoprotein E (ApoE) plays a key role in cholesterol metabolism serving as a ligand for members of the low-density lipoprotein (LDL) receptor family. Genetic variants of ApoE are associated with both atherosclerosis and Alzheimer's disease, two of the most prominent causes of death in Western society. Our lab has pursued the structure determination of biologically relevant fragments of ApoE3 as well as complexes and the fragments of several isoforms or mutants, in order to probe the structural determinates of its biological and pharmacological function. Initial efforts to determine these structures by molecular replacement were surprisingly difficult suggesting either that there was considerable variability in the structure from crystal to crystal or that the initial model was not a suitable molecular replacement probe. To resolve these problems, the structure of the 22kD fragment of ApoE3 was determined anew, to high resolution, by multiple anomalous dispersion (MAD) techniques in each of two new crystal forms and by molecular replacement (MR) in yet a third crystal form. Given these three structures we are now able to examine the variability of the structure as well as the effects of crystal packing on local conformations within the molecule. This is a useful means of demonstrating the magnitude of errors or conformational variability, residue by residue, not otherwise demonstrable by x-ray crystallographic techniques. This is particularly useful in the study of ApoE as a considerable portion of the molecule is described by weak density in all crystal forms. We are also able to compare the benefit of several crystallographic techniques such as de novo MAD phasing versus MR, or "automated structure" determination with ARPP and their effect on the ultimate coordinate error or map quality.

P06.04.092 NON-PROLINE *CIS* PEPTIDE BONDS IN PROTEINS. R. Hilgenfeld, A. Jabs, and M.S. Weiss, Institute of Molecular Biotechnology, Department of Structural Biology & Crystallography, Beutenbergstr. 11, 07745 Jena, Germany.

In a non-redundant set of 571 proteins from the Brookhaven PDB, a total of 43 non-proline *cis* peptide bonds were identified. Average geometrical parameters of the well-defined *cis* peptide bonds in proteins determined at high resolution show that some parameters, most notably the bond angle at the amide bond nitrogen, deviate significantly from the corresponding one in the *trans* conformation. Since the same feature was observed in *cis* amide bonds in small molecule structures found in the Cambridge Structural Data Base, a new set of parameters for the refinement of protein structures containing non-Pro *cis* peptide bonds is proposed.

A striking preference was observed for main-chain dihedral angles of the residues involved in *cis* peptide bonds. All residues N-terminal and most residues C-terminal to a non-Pro *cis* peptide bond (except Gly) are located in the β-region of a φ/ψ plot. Also, all of the few C-terminal residues (except Gly) located in the α-region of the φ/ψ plot constitute the start of an α-helix in the respective structure.

In the majority of cases, an intimate side-chain/side-chain interaction was observed between then flanking residues, often involving aromatic side-chains. Interestingly, most of the cases found occur in functionally important regions such as close to the active site of proteins. It is intriguing that many of the proteins containing non-proline *cis* peptide bonds are carbohydrate-binding or processing proteins.

The occurrence of these unusual peptide bonds is significantly more frequent in structures determined at high resolution than in structures determined at medium and low resolution, suggesting that these bonds may be more abundant than previously thought. We developed an algorithm for the identification of possibly overlooked *cis* peptide bonds that exploits the deviations of geometrical parameters from ideality. A few likely candidates based on our algorithm have been identified and are discussed.

P06.04.094 THE STRUCTURE OF MISTLETOE LECTIN I. H.Niwa, R.A.Palmer. Department of Crystallography, Birkbeck College, Malet street, London, WC1E 7HX, UK.

The structure of mistletoe lectin I (MLI) at 3Å resolution is presented. Mistletoe lectins from *Viscum album* are type-II ribosome inactivating proteins (RIPs), comprising a toxic A-chain and a carbohydrate binding lectin B-chain, linked by a disulphide bond. Other members of this family include the plant toxins ricin and abrin whose structures are known, and modeccin. Mistletoe lectin is of interest as a component of mistletoe extract used in an alternative medicine for cancer treatment in northern Europe. Three isolectins MLI, MLII and MLIII occur in the mistletoe plant. Although they share a similar primary structure, they differ in carbohydrate affinity and cytotoxic effects on target cells. In addition, while MLII and MLIII are monomers, MLI, the most abundant of the three, forms non-covalent bound dimers.

The structure of MLI was solved using hexagonal crystals [1] by molecular replacement using ricin as a search model and the possible dimer structure was proposed [2]. The structure has been refined to 3Å. Although MLI has structural homology with ricin and abrin, there are significant differences in some loop regions. The lectin-parts of RIPs form β-trefoil folding. MLI exists as an $[AB]_2$ dimer with internal crystallographic two-fold symmetry. Domain 1 of the B-chains are non-covalently associated by the interaction of a hairpin triplet from each molecule, forming a double trefoil structure. The disulphide bond of domain 1 of MLB at Cys20-Cys39 of the B-chain (α) is not conserved, an evolutionary mutation with respect to ricin having replaced Cys39 with serine. This mutation appears to allow the (α)

hairpin the flexibility required to take up its place at the dimer interface, and also suggests a rationale for why ricin does not form dimers.

P06.04.095 CRYSTAL STRUCTURE OF THE CELLULAR HYDROGEN PEROXIDE REGULATORS. H.-J. Choi, D.-H. Shin [1], S. W. Kang, S. G. Rhee [2], S.-E. Ryu [1], [1] Center for Cellular Switch Prottein Structure, Korea Research Institute of Bioscience and Biotechnology, Taejon 305-600, South Korea, [2] Lab of Cell Signaling, NHLBI, NIH, Maryland 20892, USA

Hydrogen peroxide (H_2O_2) has been recognized recently as an intracellular messenger that is involved in the growth factor signaling, transcription regulation and apoptosis. A family of novel peroxidases, named peroxiredoxins (Prx), regulate the intracellular concentration of H_2O_2 by reducing it in the presence of an appropriate electron donor. They regulate the activity of NF-¥êB, enhance natural killer cytotoxicity and protect cells from apoptosis. To understand the structural mechanism of the Prx enzymes, we determined the crystal structure of hORF6, a human 1-Cys Prx. The crystal structure of hORF6, which is the first to be determined among members of the Prx family, reveals a dimer of a protein containing two discrete domains where the N-terminal domain has a thioredoxin fold and the C-terminal domain is used in an arm exchange for dimerization. The active site cysteine (Cys 47), which exists as cysteine-sulfenic acid in the crystal, is located at the bottom of a relatively narrow pocket. The positively charged environment surrounding Cys 47 accounts for the peroxidase activity of the enzyme, which contains no redox cofactors. Since Cys-SOH in the ROS target proteins must be stable for a certain period of time to exert its signaling effect, the Cys-SOH stabilizing environment of the hORF6 active site pocket can be a model for the redox center of the ROS target proteins.

P06.04.096 CRYSTAL STRUCTURE OF HUMAN NUCLEOSIDE DIPHOSPHATE KINASE A. Kyeongsik Min, Sun Young Kim*, Kong-Joo Lee*, and Se Won Suh, Department of Chemistry, College of Natural Sciences, Seoul National University, Seoul 151-742, Korea, *College of Pharmacy, Ewha Womans University, Seoul 120-750, Korea.

Nucleoside diphosphate (NDP) kinases provide precursors for DNA and RNA synthesis and are involved in a variety of cellular functions. In human, several NDP kinases play important roles in proliferation, tumour metastasis, and transcriptional regulation. Human NDP kinase A, product of the *nm23-H1* gene, is a metastasis suppressor, while human NDP kinase B, product of the *nm23-H2*, is a transcription factor of the *c-myc* oncogene in addition to their enzymatic activity. NDP kinase A is a hexameric enzyme consisting of identical 17.1 kDa subunits. Although the two proteins are closely related in sequence (88% identity), they serve different cellular functions.

Crystal structure of human NDP kinase A has been solved by molecular replacement using human NDP kinase B (1) as a starting model. The model has been refined to a crystallographic R-factor of 20.7 % using 6.0–2.2 Å data. The root mean square deviations from ideal stereochemistry are 0.009 Å for bond lengths and 0.99° for bond angles.

Human NDP kinase A hexamer has D3 symmetry and can be viewed as a dimer of trimers. The six subunits are nearly identical in their structures and they fold into a compact α/β domain of 132 residues followed by a 17 residue extension at the C-terminus. The tertiary and quaternary structures are highly similar to those of other NDP kinases whose structures have been reported (2,3). A comparison of the two human NDP kinase structures provides insight into their functional differences.

P07.04.001 STRUCTURE OF PHOSPHOLIPASE A_2 FROM *DABOIA RUSSELLI PULCHELLA* AT 2.5Å RESOLUTION. Vikas Chandra, Punit Kaur and T.P.Singh, Department of Biophysics, All India Institute of Medical Sciences, New Delhi 110 029, India.

Phospholipase A_2 enzymes hydrolyze phospholipids at the sn-2 position of the glycerol backbone. The Russell's viper was classified into two classes. The class 1 contains *Viper russelli russelli, Viper russelli siamensis* and *Viper russelli formosensis* whereas class 2 has *Daboia russelli pulchella*. The sequence identity between the PLA_2's from these two classes is 47%. One of the typical differences between the sequences of the two classes is that the sequence of the class 1 contains Asn at the N-terminus, while class 2 has Ser. The novel PLA_2 from *Daboia russelli pulchella* has been crystallized in the space group $C222_1$ with unit cell dimensions a=77.01, b=92.29, c=76.90Å and contains two molecules in the asymmetric unit. The intensity data were collected to 2.5Å resolution with a completeness of 99%. The structure was solved by molecular replacement using the structure of PLA_2 from *Crotalus atrox* as a model. It has been refined to an R-factor of 0.21. The structure has revealed an entirely new form of interactions between the two molecules of the homodimer, an interesting intermix of hydrogen bonds and hydrophobic interactions. These are significantly different than those found in other homodimers and even in heterodimers involving phospholipase A_2 .

P07.04.002 STRUCTURAL CHARACTERIZATION OF THREE ARCHAEL ADENYLATE KINASES OF VARYING THERMOSTABILITY. A. R. Turner, T. Fulmer, J. Konisky, G. N. Phillips, Jr., Department of Biochemistry and Cell Biology, Rice University, Houston, TX.

We are studying the structural differences between three highly related adenylate kinases (ADKs) from three members of the *Methanococcus* genus of the Archae: the mesophile *M. voltae*, the thermophile *M. thermolithotrophicus*, and the hyperthermophile *M. jannaschii*. We have performed analytical ultracentrifugation experiments with *M. thermolithotrophicus* ADK and observed a predicted molecular weight of 100 kDa, suggesting a hexamer. Consistent with these results, dynamic light scattering (DLS) experiments predict the molecular weight to be 110 kDa. DLS data for the remaining ADKs predict similar molecular weights. Additionally, we have identified conditions under which each of these enzymes crystallize. *M. voltae* native data was collected for cubic crystals (0.2 x 0.5 mm) to 2.5 Å at BIOCARS beamline at the Advanced Photon Source. This data indexed to space group I23 with unit cell dimensions a=b=c=200.5 Å. Molecular replacement methods are currently underway using the recently solved 2.6 Å structure of the trimeric archael adenylate kinase from *Sulfolobus acidocaldarius* [1].

P07.04.003 STRUCTURAL STUDIES ON ACROSIN, A SERINE PROTEASE FOUND IN MAMMALIAN SPERMATOZOA. Rebecca Tranter[1], Roy Jones[2] and Leo Brady[1]. [1]University of Bristol, U.K. and [2]Babraham Institute, Cambridge, U.K.

Acrosin is a trypsin-like serine protease found in all mammalian spermatozoa where it plays a major role in fertilization. The protein is formed by autoactivation events at both the N and C termini of its inactive zymogen precursor, proacrosin, to yield the active heterodimer. Acrosin is thought to have two major roles in fertilization, firstly in forming specific binding interactions with receptor molecules on the surface of the ovum and secondly, in using its proteolytic activity to help sperm penetrate the extracellular matrix of the ovum. It has previously been shown that inhibition of proacrosin prevents fertilization from occurring, and this leads to interest in the protein as a target for novel contraceptive drugs. Suramin is a compound which competes with molecules on the ovum surface for binding to proacrosin and inhibits fertilization. The drug is highly toxic to humans, but has potential as a lead compound for the design of low toxicity contraceptive agents. We aim to crystallize acrosin and determine its structure by X-ray crystallography followed by structures of the protein complexed to suramin. It is envisaged that this information will aid the design of mimetics of suramin which have a lower toxicity while retaining the inhibitory effects of the drug.

P07.04.004 CRYSTALLOGRAPHIC STUDIES OF A BROAD SPECIFICITY DEHYDROGENASE. B.Dhaliwal, M.Banfield, R.L.Brady and J.J Holbrook. Department of Biochemistry, University of Bristol, Bristol BS8 1TD U.K.

2-hydroxyacid dehydrogenases are the group of enzymes that catalyse the reversible reduction of NAD^+ by 2-hydroxyacids to yield NADH and 2- keto acids in a stereospecific manner. D-hydroxyisocaproate dehydrogenase (D-HicDH) is a member of the D-2- hydroxyacid dehydrogenase family. It was discovered when a genomic library from *Lactobacillus delbrueckii* subsp. *bulgaricus* was used to complement an *E.coli* strain lacking lactate dehydrogenase and pyruvate formate lyase grown in anaerobic conditions. It is a broad specificity D-hydroxyacid dehydrogenase of commercial importance. In order to assign functions to specific amino acid residues mutants had been constructed ; most of these had reduced catalytic efficiency when compared to the wild type enzyme. Surprisingly however, a H205Q mutant was shown to have increased k_{cat} , K_M and K_i values. These properties make H205Q D-HicDH a potentially effective catalyst for use in the pharmaceutical industry where chirally pure 2-hydroxyacid derivatives are needed in the production of antihypertensives. The structure - function relationships of the wild type and H205Q mutant D-HicDH are being investigated using x-ray crystallography.

P07.04.005 CRYSTAL STRUCTURE OF Thi1, A PROTEIN INVOLVED IN DNA REPAIR AND THIAMINE BIOSYNTHESIS. P.H.C. Godoi and G. Oliva, Instituto de Química e Instituto Física de São Carlos, Universidade de São Paulo, 13560-970, CP369, São Carlos-SP, Brazil; D.D. Luche and C.F.M. Menck, Instituto de Ciências Biomédicas, Universidade de São Paulo, 05508-900, São Paulo, Brazil.

It is widely known that many diseases such as cancer, abnormal ageing processes and other genetically inherited diseases are related to DNA damage in the cell. In this project we intend to solve the structure of a recently identified protein, possibly related to DNA repair in *A. thaliana* [1].

The thi1 deleted gene, lacking the bases coding for a transit peptide into chloroplasts, was subcloned into a pET-28 plasmid vector after a 6xHis tag. This procedure allowed large-scale expression and purification of the recombinant protein on an immobilized metal chelate affinity column.

Plate crystals were obtained in two different conditions at 277K, in 800mM $(NH_4)_2SO_4$, 100mM Bicine pH8.8, and in 20% PEG6k, 100mM Bicine pH9.0. The best crystals grew after 14 days in ammonium sulfate, with maximum size of 1.5 x 1.5 x 0.05mm however attempts made in order to improve its crystal size and habit did not lead to any significant change.

Diffraction experiments intended to characterise these crystals were performed at the Brazilian Synchrotron Laboratory (LNLS) but because of its size and specially its habit, such crystals could not be mounted into capillary tubes and systematically cracked during the process. Collecting data by cryocrystallography seemed to be the best alternative but at that time the beam line has not provided cryo-cooling facilities.

In spite of it, small glass spatulas [2] have recently been used at cryogenic temperatures, since crystals hardly could be transferred to cryoloops. New trials are still in progress.

Machado, C.R. *et al.* (1996) Thi1, a thiamine biosynthetic gene in *Arabidopsis thaliana*, complements bacterial defects in DNA repair. Plant Mol. Biol. 31, 585-593
Håkon Hope, personal communication.

P07.04.006 CRYSTAL STRUCTURE OF THE COMPLEX OF CONCANAVA-LIN A AND TRIPEPTIDE YPY. Zhen Zhang, Minxie Qian, Qichen Huang and Youqi Tang, Department of Chemistry, Peking University, Beijing 100871, P. R. China; and Keyi Wang, Dafu Cui and Moyi Li, Shanghai Institute of Biochemistry, Academia Scinica, Shanghai 200031, P. R. China

Concanavalin A(ConA) is the best known plant lectin, with a specific saccharide-binding site, which has been determined by crystallographic method, and a hydrophobic binding site, which is known by indirect proof but keeps mystery in crystallography. The crystals of the complex of ConA with tripeptide YPY was acquired by soaking the crystals of ConA with two kinds of the solution of YPY, separately. The data with 2.4Å resolution was collected and the structure of the complex was refined by X-PLOR and TURBO-FRODO program to crystallographic R-factor value of 0.175 and 0.186 and free-R-factor value of 0.237 and 0.266. The space group was I222 and the asymmetric unit contains one molecule. The tripeptide binds at a site which is different from the saccharide-binding site. This site lies in the surface of ConA and was surrounded by three symmetry related molecules. It departs from Mn and Ca with the distance ca.15Å. YPY forms four or five H-bonds with ConA, depending on the solution condition, and a intramolecular H-bond. In addition, There are many hydrophobic residues near this site and the hydrophobic side chain of YPY can interact with them, which benefit the stable of YPY greatly. The site for YPY departs from saccharide site with a distance 13Å. These two binding sites neighbored each other through the residue 14N(H-Bond with saccharide) and 15T(H-bond with YPY). This relation between them may be used to explain why the binding of ConA with phage bearing hexapeptide including YPY motif can be inhibited by MeαMan[1].

P07.04.007 CRYSTALLOGRAPHIC STUDY OF DNA POLYMERASE FROM HYPERTHERMOPHILIC ARCHAEON *PYROCOCCUS KODAKARAENSIS*. H. Hashimoto†, S. Takeuchi†, T. Matsumoto†, T. Inoue†, Y. Kai†, T. Yuasa§, M. Nishioka§, S. Fujiwara§, M. Takagi§, T. Imanaka‡ Dept. of †Materials Chemistry and §Biotechnology, Osaka University, Suita, Osaka 565-0871, JAPAN ‡Dept. of Synthetic Bioligical Chemistry, Kyoto University, Yoshidahonmachi, Sakyo-ku, Kyoto 606-8501, JAPAN.

DNA polymerases are a group of enzymes that use single-stranded DNA as a template for the synthesis of the complementary DNA strand. These enzymes play an essential role in nucleic acid metabolism, including the process of DNA replication, repair and recombination. DNA polymerases can be classified into four major groups: family A, family B, family C and family X. In this study, we report crystallization and preliminary X-ray diffraction analysis of family B DNA polymerase from hyperthermophilic archaeon *Pyrococcus kodakaraensis* KOD1 (KOD DNA polymerase). KOD DNA polymerase is an enzyme that is of very considerable biological, technological, and economic importance. It is widely used in carrying out polymerase chain reaction (PCR) experiments.

KOD DNA polymerase was crystallized by the hanging-drop vapor diffusion method. All the X-ray diffraction measurements were carried out with $\lambda = 1.00$ Å synchrotron X-ray in KEK-PF, Japan. The diffraction pattern of the crystal extends to 3.0 Å resolution and a full set of diffraction data from native crystal was successfully collected at 290 K. The crystal belongs to the space group $P2_12_12_1$ and unit-cell dimensions were a =112.8, b = 115.4 and c = 75.4 Å. The presence of one molecule per asymmetric unit gives a crystal volume per protein mass (V_m) of 2.74 $Å^3Da^{-1}$ and a solvent content of 54.8% by volume. A heavy-atom derivative search is now in progress.

P07.04.008 ANALYSIS OF LIGAND BINDING TO OPPA PROTEIN BY TITRATION CALORIMETRY AND X-RAY CRYSTALLOGRAPHY. L.M.Wright, T.G.Davies, J.Woodford, J.R.Tame and R.E.Hubbard, Structural Biology Laboratory, Department of Chemistry, University of York, York, YO1 5DD, U.K.

We have examined ligand binding to the periplasmic oligopeptide binding protein OppA using isothermal calorimetry and X-ray crystallography. OppA is in several ways an ideal system for study by calorimetry since it is a highly soluble, non-aggregating protein which will bind to a variety of peptides with a fixed stoichiometry of 1:1. The affinity of peptide ligands for OppA falls within the experimental window of the technique, roughly 10^{-4}M to 10^{-8}M. The enthalpy and affinity of binding may therefore be measured and compared to the X-ray crystal structures of the protein-peptide complexes. These show that the binding pocket remains essentially constant regardless of the peptide sequence bound and all peptides are bound in the same way. From these results we hope to build a scoring function, breaking down the free energy contributions of individual groups to the overall observed free energy of binding. The structure of OppA complexed to 35 different peptides of the type Lys-X-Lys (where X is any amino acid, natural or not) show that internal water molecules play a significant role in ligand binding. The structure of the apo protein has also been determined by X-ray crystallography. Together these structures show a clear clustering of equivalent water molecules within the ligand binding site. Comparison of the structures of the different complexes and the thermodynamics of binding allow us to attempt to determine the key interactions driving binding. The use of non-natural amino acids allows us to vary the ligand very slightly and generate series of related peptides. These show that the enthalpy and entropy changes on binding vary considerably even for minor changes to the peptide and the complex. The protein exploits entropy-enthalpy compensation to accommodate a variety of chemical groups within the binding site.

P07.04.009 SRP PROTEIN TRANSLOCATION PATHWAY. T. Gariani[1],T. Samuelsson[2] & E. Sauer-Eriksson[1] ([1]UCMP, University of Umeå, [2]Department of Medical Biochemistry, Göteborg University).

Every cell must communicate with its surrounding. This is done by the help of secreted proteins. This translocation process can be achieved through two means: Signal Recognition Particle (SRP) dependent or SRP independent pathway. Translocation using the SRP dependent pathway is dependent on two control events, exerted at the SRP mediated targeting stage, and during the insertion/translocation step of the nascent protein into a proteinaceous channel on the membrane. Although most of the translocation process in bacteria is done in a SRP independent manner, the SRP subunits 4,5S RNA, Ffh and their receptor FtsY are essential for viability[(1, 2)] and their depletion results in defective protein secretion of proteins important for cell physiology (e.g FtsE/X) [(2)]. GTP is required for the functioning of FtsY[(3)]. The GTP was found to influence the protease sensitivity of FtsY indicative of a conformational change. This feature is likely to modulate the FtsY interaction with SRP. As a consequence, the SRP-mediated translocation of secretory proteins in E.Coli may be affected by the conformational state of FtsY. A mycoplasma homolog (47 kDa) to the α unit of the mammalian and E.Coli SRP receptor (FtsY) has been identified. This Mm-FtsY has a weak intrinsic GTPase activity (Kd = 3.5 μM) however a noticeable increase of this activity is recorded when the MmFtsY is combined with the N/G domain of MmFfh [(4)]. Expression and purification tests on various constructs of the MmFTSY have been conducted. Crystals of a truncated MmFTSY construct have been obtained. Data collection yielded a data set to 2.0 Å resolution and indexing showed a $P2_12_12$ space group. Expression, purification and diffraction of a Seleno-methionine derivative were as well performed in order to be able to determine the protein structure.

P07.04.010 CRYSTALLOGRAPHIC STUDIES OF HUMAN SORBITOL DEHYDROGENASE. O. El-Kabbani, R. P.-T. Chung, L.G. Sparrow, T. Iwata and D.A. Carper, Department of Medicinal Chemistry, Monash University, Parkville, Vic 3052, Australia, CSIRO, Division of Molecular Science, Parkville, Vic 3052, Australia and National Eye Institute, NIH, Bethesda, MD 20892, U.S.A.

Sorbitol dehydrogenase catalyzes the conversion of sorbitol to fructose with NAD^+ as coenzyme. Sorbitol dehydrogenase (the second enzyme) and aldose reductase (the first enzyme) comprise the polyol pathway of glucose metabolism. This pathway is believed to be involved in the development of diabetic complications. Sorbitol dehydrogenase is homologous to the long chain alcohol dehydrogenases (around 350 residues). While the tertiary structure of sorbitol dehydrogenase is yet to be determined, a model for sheep sorbitol dehydrogenase was constructed using the high resolution structure of horse alcohol dehydrogenase[1]. With only 25% overall residue identity between the two enzymes, modeling studies indicate extensive structural differences between the predicted model and the tertiary structure of sorbitol dehydrogenase, particularly in the active site region[2]. Kinetic studies of sorbitol dehydrogenase indicate that

conformational changes occur at some stage in the course of the sorbitol dehydrogenase reaction[1]. Additionally, conformational changes are of great importance in the functioning of the structurally related alcohol dehydrogenase[1]. Hence, important structural details are expected from the crystal structure determination of sorbitol dehydrogenase holoenzyme, which will be used to elucidate its catalytic mechanism. Crystals of human sorbitol dehydrogenase holoenzyme were grown from buffered ammonium sulfate solution at pH 8.5 using the hanging drop vapor diffusion method. Progress in the structure determination of human sorbitol dehydrogenase/NAD^+ complex will be presented.

P07.04.011 STRUCTURAL STUDIES ON THE A1 DOMAIN OF VON WILLEBRAND FACTOR AND A GAIN-OF-FUNCTION MUTANT. Kottayil I. Varughese, Reha Celikel And Zaverio Ruggeri. Department of Molecular and Experimental Medicine, The Scripps Research Institute, La Jolla, CA 92037.

Bleeding from damaged blood vessel is stopped by platelet adhesion and thrombus formation at the site of injury. Platelet adhesion starts when the subendothelial matrix is exposed to the blood stream and this process requires the binding of the platelet glycoprotein Ib-IX-V receptor complex to the A1 domain of von Willebrand Factor(vWF). As a part of our efforts to gain definitive information on the mechanism and regulation of this key process in hemostasis and thrombosis, we have solved the three dimensional structure of A1 domain in complex with a function blocking antibody two years ago. An intriguing pathophysiological property of the A1 domain results from the occurrence of 'gain-of-function' mutants, responsible for type IIB von Willebrand disease that enhance plasma vWF binding to GP Ibα interfering with platelet adhesion to immobilized vWF. The mechanism responsible for this effect is unknown. We have hypothesized that out of a total of 10 such mutations, three mutations alter the conformation of the A1 domain giving rise to this altered property. We have determined the crystal structure of one such mutant, I546V and interestingly there are significant conformational changes at the proposed GP-Ibα binding site. The structure of this mutant was also solved as a complex with the function blocking antibody NMC-4. The data were collected at the Stanford Synchrotron Radiation Laboratory at 90°K to a resolution of 2.0 Å.

P07.04.012 THE STRUCTURE OF A FATTY ACID CONDENSING ENZYME IN COMPLEX WITH DIFFERENT SUBSTRATES Johan Gotthardt Olsen[*], Anders Kadziola[*], Mads Siggaard-Andersen[f], Penny von Wettstein-Knowles[f], and Sine Larsen[*], [*]Centre for Crystallographic Studies, University of Copenhagen, Universitetsparken 5, 2100 Copenhagen Ø, Denmark [f]Institute of Molecular Biology, Department of Protein Chemistry, University of Copenhagen, Øster Farimagsgade 2A, 1353 Copenhagen K, Denmark

β-Ketoacyl-[Acyl Carrier Protein] I (KAS I) from *Escherichia coli* catalyses the two carbon unit elongation of fatty acids in a three step process: 1) Transfer of a fatty acyl residue from a fatty acyl-acyl carrier protein thioester (acyl-ACP) to an active site cysteine, 2) recognition of malonyl-ACP and decarboxylation of malonyl to give an acetyl-ACP carbanion, 3) carbanion attack on the carboxyl carbon of the enzyme bound fatty acid. The cysteine Sγ then acts as a leaving group and the product of the reaction is β-ketoacyl-ACP.

The crystal structure of KAS I has been determined to 2.3 Å resolution by molecular replacement using the crystal structure of KAS II [1] as a search model (38% amino acid sequence identity). Recently, diffraction data were collected from crystals of an active Cys163→Ser mutant which was demonstrated to bind the fatty acid substrate more tightly than the wild type. At the MAX Lab synchrotron in Sweden, we succeeded in getting diffraction data extending to between 2.0 and 1.85 Å resolution on several fatty acyl-enzyme thioesters. These data enable us to define a substrate binding pocket which reveals clues to substrate specificity characteritics which distinguish the KAS'es and also to suggest a model for the three step enzymatic Claisen condensation catalysed by condensing enzymes from the fatty acid biosynthetic pathways.

P07.04.013 YERSINIA ADHESIN YADA. H. Nummelin, A. Goldman [1]. Y. El Tahir, P. Ollikka, M. Skurnik [2]. [1] Department of Biochemistry and Food Technology, University of Turku, FIN-20014 Turku, Finland and Turku Centre for Biotechnology, University of Turku and Åbo Akademi University, P.O. Box 123, FIN-20521 Turku, Finland, [2] Department of Medical Biochemistry, University of Turku, FIN-20014 Turku, Finland

YadA is trimeric fibrillar outer membrane protein encoded by the Yersinia virulence plasmid [1]. YadA is largely responsible for the adhesion of Y. enterocolitica and Y. pseudotuberculosis to the intestinal tissues in vitro, through binding to the collagen, laminin and fibrinonectin in the extra cellular matrix on the surface of the host cells [1]. The structure of the binding site for collagen in most collagen-binding proteins is still unknown, because only one crystal structure in known so far [2]. We have produced and purified YadA to crystallize it and to determine its crystal structure and binding site to collagen. For the production of YadA, 78 amino acid carboxy-terminal deletion mutant of yadA of Y. enterocolitica, which encodes for monomeric protein without a membrane anchor, was constructed, cloned into pQE30 and transformed into E. coli M15. The N-terminal His-tagged protein was collected from cytoplasm by sonication and centrifugation and purified from supernatant using metal chelating affinity column and imidazole gradient. After dialysis of imidazole the protein is concentrated in dialysis bag against polyethylene glycol to 16 mg/ml. 20 mM Na-phosphate buffer, pH 7.5, 300 mM NaCl and 5 % glycerol has been used for crystallization. Initial crystal screenings have yielded small crystals.

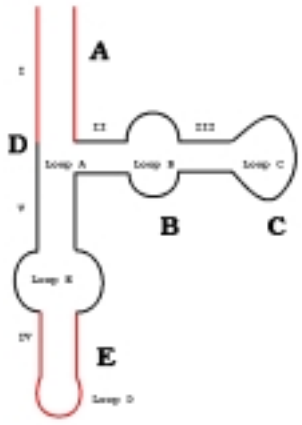
P07.04.015 UNUSUAL STRUCTURAL FEATURES IN DOMAIN A AND E OF THE RIBOSOMAL 5S RNA FROM THE BACTERIUM THERMUS FLAVUS. M. Perbandt, S. Lorenz, M. Vallazza and V.A. Erdmann, Freie Universität Berlin, Inst. für Biochemie, Thielallee 63, 14195 Berlin, Germany and Ch. Betzel, Universität Hamburg, Inst für Phys. Chemie, UKE, c/o DESY, Notkestr.85, 22603 Hamburg, Germany

The ribosomal 5S RNA is approximately 120 nucleotides long and is an integral part of the large ribosomal subunit. Several parts of the 5S rRNA interact specifically with several ribosomal proteins [1-3]. Nevertheless its precise role in protein synthesis remains unclear. It is clear that reconstituted 50S ribosomal subunits, lacking the 5S rRNA, are inactive in proteinbiosynthesis. Structural studies will support a more detailed understanding of the 5S rRNA function. Our extensive attempts to crystallise ribosomal 5S RNA have led to crystals, which diffract to about 7.5Å. For the investigation of some special features like GU basepairs and hairpin-loops in the ribosomal 5S RNA from Thermus flavus we have divided the 5S rRNA into five domains (A to E) and have solved three crystal structures: Helix I of domain A has been determined at 2.4Å. Helix V of domain E without the terminal hairpin-loop has been determined at 1.6Å and Helix V of domain E including the terminal hairpin-loop has been determined at 3.0Å. Furthermore it was possible to observe a general mode of intermolecular interaction, which occur only in RNA structures and it was possible to demonstrate the structural importance of water molecules for the stability of RNA-molecules.



P07.04.016 SEQUENCE SPECIFIC EFFECTS IN Z - DNA. N. Gautham, C. Sadasivan, P. Karthe, P Satheesh Kumar, Department of Crystallography and Biophysics, University of Madras, Guindy Campus, Chennai 600 025, India and S. Krishnaswamy School of Biotechnology, Madurai-Kamaraj University, Madurai 625 012, India

Single crystal X-ray analyses of oligonucleotides have shown that the uniform right-handed A and B type double-helical structures of DNA proposed by Watson and Crick are modulated by a sequence-dependent microheterogeneity. We have investigated the occurrence of similar sequence effects in the structure of the left-handed Z helix, which was first seen in crystals of the hexamer $d(CGCGCG)_2$ [1]. We have grown crystals of the following sequences and have obtained their structures: $d(CCCGGG)_2$, d(TGCGCG).d(CGCGCA), d(CACGCG).d(CGCGTG) and d(CGTGCG).d(CGCACG). All four hexamers crystallise as hexagonal close-packed columns of Z-DNA duplexes. However, subtle differences in the packing interactions lead to different unit cells – the first and third are orthorhombic $P2_12_12_1$, and the second and the last are monoclinic C2 and $P2_1$ respectively. Refinement of the structures lead to the following conclusions. a) The regular model of Z-DNA with a strict dinucleotide repeat, which is based on the structure of $d(CGCGCG)_2$ [2], can exist even in the presence of A.T base pairs, but for stability requires a minimum of four continuous C.G base-pairs in alternation. b) Left-handed DNA can exist even in the absence of long stretches of alternating pyrimidine-purine sequences. c) Left-handed DNA helices, like the right-handed duplexes, show polymorphism and sequence-dependent microheterogeneity.

P07.04.017 CRYSTALLIZATION AND PRELIMINARY X-RAY STUDIES OF SHORT SINGLE-STRANDED DNA FRAGMENT, D(GCGAAGC). J. Vévodová and J. Marek, Laboratory of Biomolecular Structure and Dynamics, Masaryk University Brno, Czech Republic

Studied oligonucleotide having a sequence d(GCGAAGC) has been described as an extraordinary stable hairpin structure in solution [1]. Melting point of the structure consisting of the two hydrogen bonding G-C base pairs and of the GAA loop is as high as 76.5°C, the highly stacked structure shows strong resistance against nucleases contained in *E. coli* extracts as well [1].

Crystallization trials were conducted using the Hampton Nucleic Acid Mini Screen [2]. The diffracting crystals were obtained at 4°C by the hanging drop vapor-diffusion technique from 10% MPD, 20 mM Cobalt Hexamine,12 mM NaCl, 80 mM KCl in 40 mM Sodium Cacodylate-HCl pH 5.5 solution with 35% v/v MPD as the dehydratant.

The crystals diffracting at BL711 station in MAXII synchrotron in Lund to resolution below 2 Å (at 100 K) belong to tetragonal space group $P4_32_12$ (or $P4_12_12$) with unit cell parameters a=48.28, c=63.36 Å. Structure determination is curently in progress.

The work was supported by grant No VS96095 of the Dept. of Education of the Czech Republic and by travelling grant (JM) of Svenska Institutet.

P07.04.018 ATOMIC RESOLUTION STRUCTURE OF d(GCGAATTCG). M. Soler[1], L. Malinina[1,2] and J.A. Subirana[1]. [1]Departament d'Enginyeria Química, Universitat Politècnica de Catalunya, Diagonal 647, E-08028 Barcelona, Spain. [2]Engelhardt Institute of Molecular Biology RAS, Vavilova 32, 117984 Moscow, Russia.

We present here the highest resolution B-DNA duplex obtained so far, a nonamer at 0.89Å resolution. Our results confirm the observation of Van Meervelt et al [*(1995) Nature 374, 742-744)*] that the crystal contains (CG)*G triplets as a fragment of a triple helix. The atomic resolution data set has allowed us to determine the structure of the nonamer and associated molecules and ions in great detail. We have found four fully hydrated Magnesium ions located in the major groove interacting with nucleic acid bases. The spine of hydration appears to be partially occupied by Sodium ions, with a fully hydrated Magnesium ion at one end. We have modelled some disordered phosphate groups with two possible conformations. Besides, it provides a view of a partially ordered peptide chain located on the major groove. The previous nonamer structure was determined to around 2.05Å with 2,800 unique reflections. Our structure was determined in the same space group ($P2_12_12_1$) with over 32,500 reflections.

P07.04.019 A NOVEL STRUCTURAL FORM OF A Co(II)-DNA COMPLEX. Shaunivan L. Labiuk, Lata Prasad, J. Wilson Quail, Louis T. J. Delbaere and Jeremy S. Lee. Departments of Biochemistry and Chemistry, University of Saskatchewan, 107 Wiggins Road, Saskatoon, Saskatchewan, S7N 5E5, Canada.

Zn^{2+}, Ni^{2+} and Co^{2+} (but not Mg^{2+} or Ca^{2+}) ions bind to duplex DNA at pHs above 8 and cause a conformational change which does not bind ethidium bromide. This structure has been named M-DNA ('metal'-deoxyribonucleic acid) It has been proposed that M-DNA might contain *intercalated* metal ions. So

far, the actual site of metal ion binding has remained enigmatic. A pH titration experiment showed that during M-DNA formation, protons were released. Thus it has been proposed that the metal ions in M-DNA coordinate with the imino protons of thymine and guanine bases in duplex DNA, causing a release of the corresponding protons. This conclusion, however, is speculative and it is important that a crystal structure be obtained. For this reason, a synthetic hexanucleotide was chosen and crystallization experiments were performed under conditions which promote the formation of M-DNA.

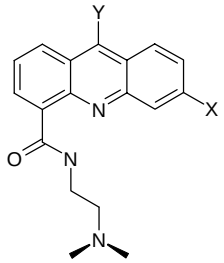
Crystals of a cobalt complex with DNA were grown at 21° C via the hanging drop equilibration technique. The hanging drops contained 0.8 mM of the synthetic self-complimentary hexanucleotide d(GGCGCC), 50 mM Tris-HCl buffer (pH 8.1) and 10 mM $CoCl_2$. The reservoir solution contained 25 % to 30 % 2-methyl-2,4-pentanediol (MPD), 50 mM Tris-HCl buffer and 10 mM $CoCl_2$.

Diffraction data were collected at the Photon Factory in Tsukuba, Japan to a maximum resolution of 2.7 Å. The tetragonal unit cell dimensions were a = b = 69.72 Å, c = 54.35 Å and $\alpha = \beta = \gamma = 90.0°$. The space group was found to be $P4_22_12$. The structural analysis is currently in progress.

This research is funded by the Medical Research Council of Canada.

P07.04.020 d(CGTACG)$_2$ WITH THE BOUND DRUGS 9-AMINO-DACA AND 9-AMINO-6BROMO-DACA AT 1.6Å AND 1.3 Å RESPECTIVELY. J.H.Thorpe, A.K.Todd, W.A.Denny, A.Adams and C.J.Cardin, Chemistry Department, University of Reading, Whiteknights, Reading, RG6 6AD, U.K. Biochemistry Department, University of Sydney, Sydney 2006, Australia, and 'Faculty of Medicine and Health Science' University of Auckland, N.Z.

DACA is an anti-tumour agent currently undergoing clinical trials in the UK, which is known to inhibit both topoisomerases I and II.



Derivatives

1 : DACA X = H, Y = H
2 : 9NH$_2$ X = H, Y = NH$_2$
3 : 6Br, 9NH$_2$ X = Br, Y = NH$_2$

The structural analyses carried out here are of the 9-amino derivatives to resolutions of 1.3 Å for the 6-bromo and 1.6 Å for the native drugs using the DNA duplex sequence d(CG(5-BrU)ACG)$_2$ and d(CGTACG)$_2$ respectively. We have shown that the 4-carboxamide side chain is located in the major groove with the precise H-bonding pattern differing for each drug examined. The 9-amino group has been shown to be the only part of the drug to extend in to the minor groove forming a rather interesting inter duplex H-bonding interaction. The existence of a spacer molecule has also been shown binding between each stacking helix exhibiting changes in the 4-carboxamide orientations of each derivative which appears to be dependent upon the pK$_a$ of the bound drug. A complete analysis of the water structure has also been achieved showing some interesting interactions, both with the DNA and the bound drug molecule.

P07.04.021 MOLECULAR DYNAMICS OF UNUSUAL NUCLEIC ACID STRUCTURES: i-DNA, G-DNA, AND ZIPPER-LIKE STRUCTURES. Jiří Šponer, J. Heyrovský Institute of Physical Chemistry, Academy of Sciences of the Czech Republic, Dolejškova 3, 182 23 Prague 8, Czech Republic, Naďa Špačková, Institute of Biophysics, Academy of Sciences of the Czech Republic, Královopolska 135, 612 65 Brno, Czech Republic and Imre Berger, Institute for Molecular Biology and Biophysics, ETH-Hönggerberg, CH-8093 Zurich, Switzerland.

We have carried out a set of nanosecond-scale molecular dynamics simulations of various unusual nucleic acid structures: four-stranded i-DNA molecules, four-stranded parallel and anti-parallel G-DNA molecules, and zipper-like duplex structures. Total length of all simulations exceeded 60 ns and the study thus belongs to the most extensive MD projects carried out on nucleic acids so far. Starting structures have been taken from high-resolution oligonucleotide crystal data and NMR studies. The calculations provided a new insight into the role of base stacking interactions in these molecules. Also the behaviour of loop regions of G-DNA molecules and the influence of cations on their stabilisation has been characterised. In most cases an excellent agreement has been found between theoretical and experimental structures. All simulations were carried out using the AMBER95 force field and the particle mesh Ewald method for long-range interactions. The simulations were supplemented with high-level ab initio calculations to estimate the accuracy of the force field and to evaluate electronic effects not included in the pair-additive force field.

P07.04.022 THE INCREDIBLE SHRINKING CRYSTAL: FORMATION OF A THREE-DIMENSIONAL DNA POLYMER, AND IMPLICATIONS FOR DNA CONDENSATION. George R. Clark and Christopher J. Squire, Chemistry Department, University of Auckland, Auckland, New Zealand, Roger F. Martin, Peter MacCallum Cancer Research Institute, Melbourne, Australia and Jonathan White, Chemistry Department, University of Melbourne, Melbourne, Australia.

During an investigation of the stereochemical basis for single-strand cleavage of DNA by iodinated Hoechst derivatives, we determined the crystal structure of the complex between the minor groove binding ligand *meta*-iodo *para*-methoxy Hoechst 33258 and the DNA dodecamer d(CGCGAATTCGCG)$_2$. It was subsequently discovered, by a series of serendipitous events, that controlled dehydration caused the crystals to shrink to approximately 75% of their initial volume, become remarkably stable, and show a dramatic improvement in the resolution of the X-ray diffraction data (from 2.4 to 1.6 Å). Crystal structures have been determined for the "normal" (solvent content 40%) and "fully shrunken" (solvent content 20%) crystals, and for a number of intermediate "partially shrunken" states. The Hoechst ligand is located in two binding sites, with opposite orientations, in the minor groove of the "normal" structure, but detaches from the DNA and re-locates into just one site in a single orientation as the crystal shrinks. The "fully shrunken" crystal exists as an infinite polymeric network, in which the dodecamer duplexes are crosslinked by coordinate bonds through magnesium cations. We have deduced a mechanism for the structural and conformational changes that occur as the crystal dehydrates and the network polymer forms. The Mg-DNA network contains 2DNA-Mg and 3DNA-Mg bridges, which provide a model for *in vivo* Mg-facilitated DNA-DNA tertiary interactions such as self-association, condensation, supercoiling and genome packaging,

and for Mg-activation of enzymes involved in nucleic acid biochemistry.

P07.04.023 STRUCTURE OF A DOUBLE-STRANDED DNA CONTAINING A CISPLATIN INTERSTRAND CROSS-LINK: CONFORMATION AND HYDRATION. Ch. Zelwer, F. Coste, L. Serre, M. Leng and J.M. Malinge, Centre de Biophysique Moléculaire, C.N.R.S., rue Charles Sadron, 45071 Orléans Cedex 2, FR, and W. Shepard, Laboratoire pour l'Utilisation du Rayonnement Electromagnétique, Université de Paris 11, 91405 Orsay Cedex, FR, and M. Roth, Institut de Biologie Structurale, 41 rue des Martyrs, 38027 Grenoble Cedex, FR.

We solved at 1.6 Å resolution the crystal structure at 100K of a double-stranded DNA decamer containing a single cisplatin interstrand cross-link, *using the anomalous scattering (MAD) of platinum as a unique source of phase information.* Cisplatin is a powerful antitumor drug whose target is cellular DNA. In the reaction between DNA and cisplatin, covalent intrastrand and interstrand cross-links are formed. Two structures of a double-stranded decamer with an interstrand cross-link (ICL) combining NMR with different conformational data from electrophoretic experiments, have been published recently[1,2]. In both models the double-helix is bent and unwound but with significantly different angle values. The crystallographic model exhibits significant differences with both solution structures, for the overall distortion parameters and the local structure of the adduct as well. The platinum coordination is plane and nearly square. The platinum residue is embedded into a cage of 9 water molecules linked to the cross-linked guanines, to the two ammine groups, and, to the phosphodiester backbone through other water molecules. This water molecule organisation is discussed in relation to the chemical stability of the interstrand cross-link, the formation of the interstrand adduct and its recognition by repair enzymes. 92 water molecules were identified after refinement based on Fobs (R= 17%) and 174 after use of the MAD phases obtained from SHARP in a REFMAC refinement based on Maximum Likelihood optimisation (R= 15%).

P07.04.024 PEPTIDE NUCLEIC ACID (PNA). -X-RAY STRUCTURAL STUDIES. H. B. Rasmussen, Biochemistry, Health Care Discovery, Novo Nordisk A/S, DK-2880 Bagsvaerd, Denmark and J.S. Kastrup, Dept. of Medicinal Chemistry, Royal Danish School of Pharmacy, DK-2100 Copenhagen, Denmark

PNA (Peptide Nucleic Acid) is an oligonucleotide analogue in which the entire backbone has been replaced by a backbone composed of N(2-aminethyl)glycine units [1]. PNA hybridises with both DNA and RNA and possess many of the properties desired of an antisense/antigene drug candidate, including stability towards nucleases, proteases, peptidases and human serum.

X-ray structural determination at 1.7 Å resolution of a PNA-PNA duplex [2] verified that a double helical structure can occur without the presence of either DNA or RNA. Furthermore the structure revealed a unique helix (P-form) among known Watson-Crick base paired helices.

	Twist	Rise	Base tilt	Displacement	Bases per turn
PNA P-form	19.8	3.2Å	1.0	8.3 Å	18
DNA B-form	36.0	3.4Å	0.0	-0.1 Å	10

In order to elucidate the dependence of the helical form on the bases and the backbone, we have crystallised and solved the structure of different analogues with modifications in either base or backbone. Furthermore to provide information on the inducement of helical handedness by chiral amoino acids, we have solved the structure of a complex where a chiral center have been introduced. Latest we have crystallised a PNA dodecamer (2.7Å resolution) a non complementary PNA decamer (2.2Å resolution).

Egholm, M. Buchardt, O. Christensen, L., Behrens, C., Freier, S. M., Driver, D.A., Berg, R.H., Kim, S.K., Norden, B. & Nielsen, P.E. (1993) Nature 365, 565.

P07.04.025 STRUCTURE AND RECOGNITION OF TANDEM G.A BASE PAIRS ASSOCIATED WITH HUMAN CENTROMERE SEQUENCE. Y.-G. Gao, H. Robinson, A. H.-J. Wang, University of Illinois at U/C, Urbana, IL 61801 USA and R. Sanishvili, A. Joachimiak, Argonne National Lab, Argonne IL 60439 USA

G.A mismatched base pairs are frequently found in nucleic acids. Centromere DNA sequences contain unusual repeating motifs, e.g., (GAATG)n.(CATTC)n found in human chromosome. The purine-rich strand of this repeating pentamer sequence forms duplex and hairpin structures with unusual stability. The high stability of those structures is contributed by the "sheared" G.A base pairs and such base pairs present a novel recognition surface for ligands and proteins. We have solved the crystal structure, by the multiple wavelength anomalous (MAD) method, of a DNA decamer in which the centromere core sequence motif GAATG is embedded. Three crystal forms were refined to near-atomic resolution. The structures reveal the detailed conformation of tandem G.A base pairs and their unique hydrogen bonding surface has interesting interactions with bases, cobalt(III) hexaammine, hydrated magnesium ion and water molecules. The results are relevant in the understanding of the structure associated with human centromere sequence in particular and G.A base pairs in nucleic acids in general.

Supported by NSF (MCB 98-0829) and NIH (GM 41612)

P07.04.027 CRYSTALLOGRAPHIC STUDIES ON DNA DAMAGE AND MUTATION. T. Chatake[1], A. Ono[2], Y. Ueno[3], A. Matsuda[3] and A. Takénaka[1] [1]Faculty of Bioscience and Biotechnology, Tokyo Institute of Technology, Nagatsuda, Midori-ku, Yokohama 226-8501, Japan, [2]Graduate School of Science, Tokyo Metropolitan University, Hachioji, Tokyo, 192-0364, Japan, and [3]Graduate School of Pharmaceutical Sciences, Hokkaido University, Nishi 6, Kita 12, Kita-ku, Sapporo 060-0812, Japan

DNA replication in biological systems always requires the highest accuracy. Some mutagens cause several mutations including cancer, which may be ascribed to the mis-matching in the Watson-Crick base pairing. Extensive studies showed that oxyamine such as hydroxyamine and methoxyamine attacks amino groups of DNA bases. When an adenosine residue on the template DNA is methoxylated, not only thymidine but also cytidine residues are incorporated into the opposite strand of newly synthesiz-ing DNA. In order to elucidate the reason why DNA polymerase allows such a transition between pyrimidines, two DNA dodecamers with the nucleotide sequence of d(CGCGXATYCGCG), where X is commonly deoxy-N^6-methoxyadenosine and Y is deoxythymidine or deoxycytidine, have been synthesized and their crystal structures determined.

Both the two dodecamers have no significant conformational changes from the original B-form dodecamer (Shui *et al*., *Biochem*. 37, 8341-8355, 1998). The adenosine residues form a typical Watson-Crick type base pair with the

thymidine residues even methoxylated. On the other hand, the electron density map clearly indicates that the methoxyadenosine residue forms a pair with the cytidine residue through the two hydrogen bonds, N6(ade)...N4(cyt) and N1(ade)...N3(cyt). This paring is identical to the canonical Watson-Crick base pairing. For these hydrogen bonds, methoxyadenosine should take an imino form through tautomerization allowed by methoxylation. The imino form has donor-acceptor sites for hydrogen bonding similar to those of guanine base. Therefore, it is concluded that methoxylation makes adenosine possible to mimic guanosine and so cytidine residue is mis-incorporated by DNA polymerase into the opposite strand.

P07.04.028 ULTRA HIGH RESOLUTION DNA STRUCTURES. H. Robinson, Y.-G. Gao, A. H.-J. Wang, University of Illinois at U/C, Urbana, IL 61801 USA and R. Sanishvili, A. Joachimiak, Argonne National Lab, Argonne IL 60439 USA

Recent advances in X-ray crystallography have allowed the study of a variety of DNA structures at resolution beyond 1.0 Å. We have examined structures in several different types of conformations, e.g., B-DNA, A-DNA, Z-DNA, DNA with unusual base pairing and DNA/drug complexes. From these studies we are able to provide improved parameterization for structures that must be examined at lower resolution. This improved characterization of DNA structures is especially useful in handling disordered segments of the DNA backbone. At low resolution, disordered segments often are incompletely resolved and thus are modeled as a single model intermediate between two more stable conformations. With these improved characterizations of structures at ultra high resolution, the low resolution disordered regions of DNA structures can be recognized and modeled more effectively. Examples of several ultra high resolution DNA structures will be presented.

Supported by NSF (MCB 98-08298) and NIH (GM41612)

P07.04.029 STRUCTURE OF A PSORALEN CROSS-LINKED DNA DUPLEX P. Shing Ho, Brandt Eichman, Blaine Mooers [1], Marie Alberti, John Hearst [2], [1] Department of Biochemistry and Biophysics, Oregon State University, Corvallis, OR 97331, USA, [2] Lawrence Berkeley Lab, 1 Cyclotron Road, Berkeley, CA 94720, USA

Psoralen is class of photochemotheraputic agents that cross-link the two-strands of a DNA double-helix. The structure of a psoralen-DNA adduct was first determined in solution by NMR (1). The highly bent conformation of the DNA observed in this structure, however, was not consistent with gel mobility studies which showed that the DNA remains unbent in the adduct (2, 3). We have crystallized the psoralen adduct of the self-complementary sequence d(CGCGTACGCG), where the two thymine bases of the duplex are covalently cross-linked by the drug. The crystals diffract to 2.2 Å resolution, and are in the monoclinic space group C2, with unit cell parameters of a = 70.2 Å, b = 23.4 Å, c = 37.1 Å, and beta = 112.2°. The DNA in the crystal is linear B-DNA, consistent with the solution studies (2, 3), with an average helical rise of 3.36 Å. The central T-A base pairs are unwound by 32° by the intercalated drug. This structure, therefore, shows the details of the distortions induced by the intercalation and covalent cross-link formed with the drug, as well as the solvent rearrangements resulting from these distortions.

P07.04.031 A METJ VARIANT INTERACTS WITH NON-PALINDROMIC DNA SEQUENCES. H.C. Dawkes and S.E.V. Phillips, School of Biochemistry and Molecular Biology, University of Leeds, Leeds LS2 9JT,UK, and S. Elworthy and P. G. Stockley, School of Biology, University of Leeds, Leeds, LS2 9JT, UK .

MetJ is the methionine repressor responsible for the methionine biosynthesis in *Escherichia coli*. In the presence of its co-repressor S-adenosyl methionine (SAM), MetJ dimers bind to arrays of palindromic 8-base pair DNA consensus sequences of the type AGACGTCT, termed the met box [1]

Specific recognition of two base pairs in the DNA operator occurs via hydrogen bonds from Lys23 and Thr25 of MetJ to base edges in the major groove. A long side chain is thought to be required at position 23 and a short side chain required at position 25 [2]. Substitutions were made at these positions producing the variant K23S/T25R. SELEX experiments revealed a reduced affinity for the palindromic met box, instead displaying a preference for non-palindromic sequences.

Previous crystallographic studies of wild-type MetJ reveals the dimer binds to the met box contacting equivalent phosphate residues at two distinct sites in the palindromic DNA sequence. Since K23S/T25R recognises a non-palindromic sequence, its interaction with DNA should be unique and unsymmetrical.

MetJ K23S/T25R crystals diffract to 2.8Å and co-crystallisation with non-palindromic DNA sequences should reveal details of both protein dimer-dimer interactions and protein-DNA interactions.

P07.04.032 THE STRUCTURE OF AHRC, THE ARGININE REPRESSOR/ACTIVATOR PROTEIN FROM BACILLUS SUBTILIS. Caitríona Dennis, Mark Parsons and Simon Phillips, School of Biochemistry and Molecular Biology, University of Leeds, Leeds, U.K., and Nicholas Glykos, IMBB, PO BOX 1527, 71110 Heraklion, Crete, Greece.

The structure of AhrC, the site-specific DNA-binding protein from *B. Subtilis* which controls the concentration of the amino acid arginine, has been solved to 2.7 Å using combined phases from molecular replacement and a heavy atom derivative. AhrC functions in response to elevated concentration of L-arginine. It both represses the transcription of arginine biosynthetic genes and activates transcription of arginine catabolic genes. Unusually for a DNA-binding protein, AhrC is a hexamer and is proposed to interact with one, two or three DNA recognition sequences within the control regions of arginine biosynthetic and catabolic genes.

Crystals of AhrC are orthorhombic and contain 1 hexamer in the asymmetric unit. The hexamer is made of 6 monomers containing 2 domains - an oligomerisation domain and a DNA-binding domain. A molecular replacement solution was obtained using the hexameric core structure (oligomerisation domains) from ArgR, a homologous protein from *E.coli* as a trial model. Phase information from a Niobium Cluster derivative was used to help find the DNA-binding domains.

Refinement of this structure is currently underway, 6 fold averaging and the maximum likelihood option of CNS is being incorporated. The structure looks symmetrical only within the core domains. The DNA-binding domains adopts slightly different orientations around this core hexamer with little interactions between their corresponding oligomerisation domain and with other DNA-binding domains.

P07.04.033 1.0Å AND ENZYME-DNA COMPLEX STRUCTURES OF ENDONUCLEASE IV REVEAL SPECIFICITY FOR DAMAGE RECOGNITION AND CATALYSIS. D.J. Hosfield, Y. Guan, and J.A. Tainer, Dept. of Molecular Biology and the Skaggs Institute for Chemical Biology, The Scripps Research Institute, La Jolla, CA 92037, USA, and B.J. Haas, and R.P. Cunningham, Dept. of Biological Sciences, Center for Biochemistry and Biophysics, State University of New York-Albany, Albany, NY 12222, USA.

The long term viability and propagation of all living cells depend upon a number of ubiquitous DNA repair pathways. A major DNA damage intermediate in these pathways, resulting from oxidative, enzymatic, and spontaneous processes, is an abasic site, which can be detected and processed by Endonuclease IV (Endo IV). This evolutionarily conserved, Zn-dependent metallo-endonuclease specifically recognizes abasic sites and catalyzes the first step of their release from duplex DNA.

The structure of *Escherichia coli* Endo IV was determined using MAD techniques with data collected from four wavelengths near the Zn absorption edge, and refined against high resolution data that extends to 1.0Å resolution. Anisotropic B-factor refinement, using the program Shelx-97, gave a final model with excellent stereochemistry and R=12.6% (R_{free}=15.0%). This structure provides accurate measures of bond lengths and bond angles, and provides, to the best of our knowledge, the highest resolution description of a tri-nuclear Zn cluster yet obtained by X-ray crystallography. The mechanism of abasic site binding and chemical catalysis was elucidated by analysis of both a wild-type and site directed mutant complex of Endo IV bound to duplex DNA containing a centrally located abasic site analogue. In the mutant structure the scissile P-O3' bond remains intact while in the wild-type complex this bond is broken. These two structures characterize substrate and product complexes and in combination with the 1.0Å enzyme structure resolve key issues and provide a detailed mechanism regarding the chemical events and subtle structural changes underlying DNA damage recognition and chemical catalysis.

P07.04.034 CRYSTALLISATION AND PRELIMINARY X-RAY CRYSTALLOGRAPHIC ANALYSIS OF BACTERIOPHAGE T7 ENDONUCLEASE I: A HOLLIDAY JUNCTION RESOLVING ENZYME. J.M. Hadden, M.A. Convery and S.E.V. Phillips, Department of Biochemistry and Molecular Biology, University of Leeds, Leeds, LS2 9JT, UK. N. Ito, Biomolecular Engineering Research Institute (BERI), 6-2-3 Furuedai, Suita, Osaka 565, JAPAN. A. Declais and D.M.J. Lilley, CRC Nucleic Acid Structure Group, Department of Biochemistry, University of Dundee, DD1 4HN, UK.

Genetic recombination is a fundamental process in the evolution of all living organisms. This process results in the exchange of sequences between DNA segments and plays a fundamental role in the production of new genetic variants. The four-way DNA (Holliday) junction is an important intermediate in the recombination process.

Bacteriophage T7 encodes a 149 amino acid residue protein, endonuclease I, which has been shown to bind and cleave four-way DNA junctions *in vitro*. A number of mutants of T7 endonuclease I have been isolated that bind, but do not cleave DNA junctions. These mutants are particularly useful for studying the binding process.

We have crystallised one such mutant both unbound and in complex with a synthetic Holliday junction.

Crystals of the isolated protein belong to the space group $P2_12_12$ and have cell dimensions of a=123.2Å, b=134.8Å and c=61.2Å. These crystals were found to diffract beyond 2Å at the ESRF. Our best quality data set has been processed to 2.8Å and has the following statistics; R_{merge} 4.5%, 99.4% complete with a multiplicity of 3.8 and I/σI of 6.4. Crystals of the protein in complex with DNA belong to the space group $P4_22_12$ and have cell dimensions of a=77.3Å, b=77.3Å, c=151.3Å. A data set has been processed to 3.5Å and has the following statistics; R_{merge} 10.5%, 98.2% complete with a multiplicity of 5.6 and I/σI of 1.8.

We are currently in the process of screening for heavy atom derivatives for both crystal types. We have also introduced several methionine residues into the protein and are in the process of substituting these with selinomethionine.

P07.04.035 TYPE II RESTRICTION ENDO-NUCLEASES: STRUCTURE, FUNCTION AND ENGINEERING OF NOVEL PROPERTIES. A.K. Roidis and M. Kokkinidis, University of Crete, Dept. of Biology, PO Box 2208, GR-71409 Heraklion, Crete, Greece and Institute of Molecular Biology and Biotechnology (IMBB), PO Box 1527, GR-71110, Heraklion, Crete, Greece.

Type II restriction endonucleases provide a rich source of information about protein-DNA interactions. They have gained an enormous importance in Molecular Biology due to their applications in recombinant DNA technologies, genome mapping, manipulation of chromosomes and health care. Recent crystallographic studies have revealed novel DNA-binding motifs and new modes of DNA recognition. To understand the precise mechanisms underlying sequence specific DNA recognition we have initiated crystallographic studies of wild type and mutated restriction endonucleases *Eag*I and *Pvu*II [1] in the apoenzyme form and as complexes with DNA. The aim of these studies is to develop novel specificities by protein engineering and to examine systematically the roles of individual residues and bases involved in specific and non-specific binding.

P07.04.036 STRUCTURAL DATA OF THE TRANSCRIPTION COFACTOR PC4. Sjors H.W. Scheres, Jeroen Brandsen, Jean M.H. van den Elsen, Jan Kroon, Piet Gros; Dept. of Crystal and Structural Chemistry, Bijvoet Center for Biomolecular Research, Utrecht University; Padualaan 8, 3584 CH Utrecht, The Netherlands

PC4 (human positive cofactor 4) is a transcription cofactor that can both coactivate and repress activator dependent class II gene transcription. The structure of the C-terminal domain (residues 63-127) has been solved by X-ray diffraction in our lab [1]. This structure shows a new structural motif reminiscent of the single stranded (ss)DNA-binding motif in human replication protein A. The orientation of the binding grooves on the dimer suggests that two ssDNA strands running in opposite directions can be bound to the protein. This agrees with the biochemical findings that heteroduplex DNA can be bound to the protein with high affinity. This binding mode is most likely involved in the repressing mode of PC4 [2].

For its role as coactivator the N-terminal domain plays a more prominent role. Recent biochemical studies have shown that in the absence of transcription factor IIH (TFIIH) the activator function of PC4 is lost and transcription is strongly repressed by PC4 [3]. In the same study it has been shown that PC4 can be phosphorylated by TFIIH and TFIID. Most likely, phosphorylation is to take place on the serine-rich N-terminal domain of PC4. To understand more of the coactivator function new crystals were grown of PC4. Up till now however the structure of this construct could not be solved because of twinning in the crystals.

Here we present structural data of PC4 in the context of its combined role of both coactivator and repressor and the twinning of the new crystals is discussed.

P07.04.037 THE STRUCTURE OF THE OCTAMERIC RUVA-HOLLIDAY JUNCTION COMPLEX. S.M. Roe, M. Oram, A. Keeley, I. Tsaneva and L.H. Pearl, Dept. of Biochemistry and Molecular Biology, University College London, Gower Street, London WC1E 6BT, UK, and T. Barlow and T. Brown, Dept. of Chemistry, University of Southampton, Highfield, Southampton, SO17 1BJ, UK.

Holliday junctions, created by exchange of strands between homologous DNA molecules, occur as intermediates in homologous recombination and double strand DNA break repair. The main pathway for processing the junctions in bacteria involves the RuvABC proteins.

RuvA binds specifically to the Holliday junction and isomerises the DNA from a stacked-X structure to a square-planar structure. RuvB is a DNA-dependant ATPase. It forms hexameric rings around the DNA and provides the motor of branch migration, but has no specificity for Holliday junctions without RuvA. RuvA and RuvB have been shown to form a complex which promotes ATP-dependant branch migration. RuvC is a junction-specific endonuclease, which resolves the junction to reform separate duplex DNA molecules.

Previous crystallographic studies of *E. coli* RuvA have shown the creation of a square-planar tetrameric complex, and have suggested a model for the interaction with DNA. We have determined the structure of *M. leprae* RuvA complexed with a synthetic Holliday junction, to 3.0Å. This clearly shows the RuvA to be an octameric shell with four tunnels through which the DNA can slide. The octamer is stabilised by the presence of a conserved tetramer-tetramer interface and we believe it to be the probable in vivo structure for the branch migration complex.

Although the Holliday junction itself suffers from statistical disorder, we are able to define key residues involved in DNA binding and suggest a mechanism for strand separation by RuvA. Labelling of the DNA is being carried out to determine the extent of the disorder.

P07.04.038 STRUCTURE-FUNCTION STUDIES ON RESIDUES OF PURR INVOLVED IN COREPRESSOR BINDING AND ALLOSTERISM. Joy L. Huffman and Richard G. Brennan, Department of Biochemistry, Oregon Health Sciences University, Portland, OR, U.S.A.

The crystal structures of corepressor-bound and free *E. coli* Purine Repressor (PurR) have implicated several residues in corepressor binding and specificity and intramolecular signal transduction (allosterism). Residue W147 is key for the allosteric response, but in most members of the LacI/GalR family, position 147 is an arginine. Three substitutions at residue 147 have been characterized *in vivo* and *in vitro*. PurR (W147F) displays a decreased affinity for both operator and corepressor. PurR (W147A) and (W147R), on the other hand, act as super repressors *in vivo*. Each of the mutant PurR holo complexes has crystallized isomorphously to wild-type. Interestingly, only the W147F apo complex has crystallized but is isomorphous to wild-type. Structures of these mutants have been solved beyond 2.7 Å using molecular substitution. Since the corepressor binding site is over 40 Å from the DNA binding domain, structural studies on these mutants should further our understanding of the allosteric regulation of DNA binding proteins.

Additional mutations have been made within the corepressor binding pocket to augment our thermodynamic and structural understanding of ligand specificity. Under study are residues R190, which is the corepressor identity determinant of the *E. coli* PurR, and T192 which contacts the N7 and C8 atoms of the corepressor. The effects of a smaller basic residue at position 190, which is observed in the *H. influenza* PurR, and the loss of a hydrogen bond and van der Waals contact on corepressor binding and affinity will be discussed and their structures presented.

P07.04.039 THE STRUCTURAL BASIS OF DUAL-FUNCTION TRANSCRIPTIONAL CONTROL IN THE LYSR FAMILY PROTEIN, CYSB. K.H.G. Verschueren, C. Addy, G.N. Murshudov, E.J. Dodson, A.J. Wilkinson. Structural Biology Laboratory, University of York, York YO1 5DD, UK.

The LysR-type transcriptional regulators (LTTRs) form a large family of bacterial gene activator proteins which control the expression of genes associated with a multitude of highly diverse cellular processes. They act either as tetramers or dimers of identical polypeptides, 270-330 amino acid residues in length and share stretches of sequence similarity over ~270 residues of which the strongest conservation lies in their N-terminal DNA binding domain.

We are investigating the mechanism of transcriptional regulation by CysB, an LTTR involved in cysteine biosynthesis in Gram-negative bacteria. The proteins involved in the process are highly regulated and this regulation is dependent on the activity of CysB, a tetrameric protein of identical 36 kDa subunits (324 residues). Like most LysR family proteins, CysB has a dual regulatory function, acting as transcriptional activator at one or several *loci* whilst negatively regulating transcription of its own gene. The interactions of CysB with *cys* promoters have been shown to be extremely complex.

The 1.8Å crystal structure of a dimeric chymotryptic fragment of CysB from *Klebsiella aerogenes*, residues 88-324, containing the cofactor-binding domain has been elucidated using a combination of MIR techniques and multi-crystal averaging. The core of the structure consists of two α/β domains connected by a short two-stranded hinge region. A deep cavity formed between the two domains represents the inducer binding site and is occupied by a sulphate anion. The inducer binding domain of the monomer closely resembles those of the IPTG and hypoxanthine binding domains of *lac* repressor and PurR respectively. However the subunit organisation of the two molecules in the CysB(88-324) dimer is quite different to that in *lac* repressor and PurR. Whereas in the latter the two-fold axis of symmetry relating monomers in the dimer is parallel to the long axis of the cofactor binding domain, in CysB(88-324) it is perpendicular to this axis. This is expected to position the N-terminal DNA binding domains at opposite ends of the molecule perhaps accounting for the unusually large DNA footprints produced by CysB. Recently we have obtained well-diffracting crystals of the intact CysB(1-324). We hope to present the structure of the full-length CysB at the meeting.

P07.04.040 THE STRUCTURE OF PLASMID-ENCODED TRANSCRIPTIONAL REPRESSOR CopG, UNLIGANDED AND BOUND TO ITS OPERATOR. M. Coll, F.X. Gomis-Rüth, M. Solà, A. Párraga, A. Guasch, Institut de Biologia Molecular de Barcelona, CSIC, Jordi Girona 18, 08034 Barcelona, Spain, P. Acebo, M. Espinosa, G. del Solar, Centro de Investigaciones Biológicas, CSIC, Velázquez, 144, 28006 Madrid, Spain, R. Eritja, EMBL, Meyerhofstraße 1, 69117 Heidelberg, Germany and A. González, EMBL, c/o DESY, Notkestraße 85, 22603 Hamburg, Germany.

The structure of the transcriptional repressor CopG has been solved unliganded and bound to its target operator DNA. The protein, encoded by the promiscuous streptococcal plasmid pMV158, is involved in the control of plasmid copy number. The structure of this repressor, which is the shortest reported to date and the first isolated from a plasmid, has a homodimeric ribbon-

helix-helix arrangement. CopG cooperatively associates, completely protecting several turns on one face of the double helix in both directions from a 13-bp pseudosymmetric primary DNA recognition element. In the complex structure, one protein tetramer binds at one face of a 19-bp oligonucleotide containing the operator, with two β-ribbons inserted into the major groove. The DNA is bent 60^{o} by compression of both major and minor grooves. The protein dimer displays topological similarity with Arc and MetJ repressors. Nevertheless, the functional tetramer has a unique structure with the two vicinal recognition ribbon elements at a short distance, thus inducing strong DNA bend. Further structural resemblance is found with helix-turn-helix regions of unrelated DNA-binding proteins. In contrast to these, however, in CopG the bihelical region has a role in oligomerization instead of DNA recognition.

P07.04.041 CRYSTAL STRUCTURE OF A HUMAN TFIIB-TBP-DNA COMPLEX AT 2.65 A RESOLUTION F.T.F. Tsai [1], and P.B. Sigler [1,2], [1] Department of Molecular Biophysics and Biochemistry, [2] Howard Hughes Medical Institute

The TATA-box binding protein (TBP) and transcription factor IIB (TFIIB) belong to a set of general transcription factors (GTFs) that is a key component of the RNA Polymerase II pre-initiation complex. The latter assembles on a promoter and is required for the transcription of all protein encoding genes in eukaryotes and archaea. The crystal structure of several GTF-DNA complexes, including that of a eukaryotic and archaeal TBP-TFIIB-DNA complex, respectively, have been solved. However, despite of the overall structural similarities, the two structures differ with respect to the relative orientation of the TBP bound to the promoter. It is believed that the determinant for this polarity may lie in the sequence immediately upstream of the TATA-box, the so-called IIB recognition element (BRE), which was absent in both previously solved crystal structures.

Here we present the crystal structure of a human ternary TFIIBc-TBPc-DNA complex at 2.65 A resolution, containing one version of the selection-optimised BRE. The crystals belong to the monoclinic space group, P21, with unit cell dimensions: a=118.5 A, b=122.3 A, c=140.2 A, and beta=113.1 degrees. The structure was determined essentially by molecular replacement and revealed the presence of five ternary complexes per asymmetric unit, which together have a molecular weight of nearly 300 kDa. The five ternary complexes were found to stack head-to-tail and were held in helical register by the G:C base pairs of the 5' overhang. We are currently refining this structure using simulated annealing and improper NCS.

P07.04.042 CRYSTAL STRUCTURES OF THE 64M-2 ANTIBODY FAB FRAGMENT AND ITS COMPLEXES WITH DNA (6-4) PHOTOPRODUCTS. H. Yokoyama, R. Mizutani, and Y. Satow, Graduate School of Pharmaceutical Sciences, University of Tokyo, Tokyo 113-0033, Japan, Y. Komatsu and E. Ohtsuka, Graduate School of Pharmaceutical Sciences, Hokkaido University, Sapporo 060-0812, Japan, O. Nikaido, Faculty of Pharmaceutical Sciences, Kanazawa University, Kanazawa 920-0934, Japan.

The 64M-2 murine antibody recognizes ultraviolet-induced (6-4) DNA photoproducts. In order to elucidate the structure of the (6-4) photoproducts as well as recognition mechanisms by the antibody, we determined the crystal structures of the 64M-2 Fab fragment and of its complexes with the (6-4) photoproducts of dT(6-4)T (d2mer) and dTT(6-4)TT (d4mer) by the molecular replacement method.

The native Fab structure was refined to an *R* factor 0.163, the d2mer complexed one to 0.199, and the d4mer complexed one to 0.209. In these complexes obtained at 2.4 Å resolution, the side-chains of Trp 33H, His 35H, Arg 95H, and Tyr 100iH interact with the bases of the T(6-4)T moiety through hydrogen bonds and van der Waals contacts. One of the planes of the bases is nearly perpendicular to the other. This is ascribable to the conformational restraints on the covalent (6-4) bond from the base moiety. The 5'- and 3'-side bases are in the *anti* and *high-anti* conformation relative to each deoxyribose ring, respectively. The torsion angles ζ and α for the phosphodiester bonds, O3'-P and P-O5' of the T(6-4)T moiety, are in the *gauche*$^{-}$ and *gauche*$^{-}$ range, respectively. The torsion angle γ about C5'-C4' bond is in the *gauche*$^{+}$ range. Tyr 32L, Leu 93L, and Ser 58H are situated near the sugar-phosphate backbone of the T(6-4)T moiety. In the d4mer complex, 5'- and 3'-side phosphate groups adjacent to the T(6-4)T moiety form hydrogen bonds with the side-chains of Asn 28L and Ser 58H, respectively. The thymine base at the 5'-terminal is in interaction with Tyr 32L, Lys 50L, and Tyr 100iH, whereas the thymine base at the 3'-terminal is not in contacts with the Fab.

P07.04.043 THE BIPARTITE DNA BINDING DOMAIN OF C. ELEGANS TC3 TRANSPOSASE BOUND TO TRANSPOSON DNA. Titia K. Sixma, Gertie van Pouderoyen, René F. Ketting*, George Verlaan*, Ronald H.A. Plasterk*, Divisions of Molecular Carcinogenesis and *Molecular Biology, Netherlands Cancer Institute, Plesmanlaan 121,1066 CX Amsterdam, Sixma@nki.nl.

Transposons are regions of DNA that 'jump' in the genome. They encode specific proteins to make this possible. In the Tc1/mariner class of transposons this is accomplished by a single transposase protein, which excises the transposon DNA and inserts it elsewhere. To understand the recognition of the Tc3 transposase for the transposon DNA we are studying crystal structures of the binding domains of C. elegans Tc3A complexed to the recognition region of the DNA.

The bipartite DNA binding domain of Tc3A has been crystallized in complex with the recognition region on the Tc3 transposon. Crystals were successfully designed to retain the packing found with the N-terminal protein domain and a smaller oligomer [1], by extension with precisely one half turn of DNA. The N-terminal domain structure [1] was used to solve the structure of the bipartite domain to 2.6 Å using molecular replacement.

The second DNA binding domain binds in the major groove. The linker extends through the minor groove. It is not yet clear whether the second domain in the second molecule in the asymmetric unit also binds DNA. Further refinement and a heavy atom derivative search are in progress.

[1] van Pouderoyen, G., Ketting, R., Perrakis, A., Plasterk, R., Sixma, T.K., EMBO J. 16 (1997) 6044-6054.

P07.04.044 CRYSTAL STRUCTURE OF A SYNAPTIC CRE RECOMBINASE - *LOX*P COMPLEX. D. Suck, J.E.W. Meyer, F. Buchholz, H. Dreher, F. Stewart, EMBL, Meyerhofstr.1, D-69117 Heidelberg, Germany.

The structure of a synaptic Cre recombinase - DNA complex has been determined at 3.2Å resolution from orthorhombic crystals containing four Cre monomers bound to two synapsed wild-type *lox*P sites in the asymmetric unit. The structure suggests that a Cre-induced kink in the spacer region initiates first-strand cleavage during site-specific recombination.

The 38.5 kD Cre protein from phage P1 belongs to the λ integrase family of site-specific recombinases which proceed through the formation of a Holliday junction and a covalent phosphotyrosine protein-DNA intermediate. Cre recognizes a 34bp target site ("*lox*P site") consisting of two 13bp repeats separated by an non-symmetric 8bp spacer.

Data were collected under cryo conditions at the BW7B beamline at the EMBL outstation in Hamburg and the structure was solved by molecular replacement (AMoRe) using the coordinates of a complex containing Cre bound to a symmetrized *lox*-site formed from a 16mer and 19mer oligonucleotide [1]. Applying tight geometric and B-factor restraints, and adding independent phase information from an EMTS derivative (SHARP), the Cre-*lox*P structure was refined to an R-factor of 21.8% (R_{free} = 27.0%) using the program Refmac.

The tetrameric Cre-*lox*P complex shows local 2-fold symmetry with an arrangement of subunits closely resembling that seen in the structure solved by van Duyne and coworkers [1]. There are however slight, but significant changes in quaternary structure involving rigid body movements of domains and furthermore, while two of the subunits are closely similar in structure to the Cre-*lox*A [1] complex, the other two show distinct differences, particularly around the active site and the linker region between N- and C-terminal domains.

A striking feature of the synaptic Cre-*lox*P structure is a kink in the spacer region of the DNA adjacent to the first strand cleavage site associated with a 45 degree major groove-directed roll and complete unstacking of bases at this step. This finding may provide an explanation for the observed order of strand exchange in Cre-induced recombination.

P07.04.045 CRYSTAL STRUCTURE OF IRF-2 COMPLEXED WITH DNA CONTAINING A TANDEM REPEAT OF CORE SEQUENCES. T.Shimizu, Y.Fujii, M.Kusumoto, T.Hakoshima [1], Y.Kyogoku[2], T.Taniguchi[3], [1] Department of Molecular Biology, Nara Institute of Science and Technology, Takayama Ikoma Nara, Japan. [2] Institute for Protein Research, Osaka University, Yamadaoka Suita Osaka, Japan. [3] Department of Immunology, Graduate School of Medicine, University of Tokyo, Hongo Bunkyoku Tokyo, Japan

The family of interferon regulatory factor(IRF) transcription factors is important in the regulation of interferons(IFNs) in response to infection by virus and in the regulation of interferon-inducible genes. IRF-2 was originally identified as a competitor of IRF-1, a transcriptional activator of the interferon system. In addition, IRF-2 and IRF-1 are also involved in several regulatory processes and immune systems.

The family shows extensive homology among their DNA-binding domains in the N-terminal regions. IRF members are believed to bind to similar DNA sequences with tandem repeats of GAAA with mostly two inserted bases.

The crystal structure of IRF-1 bound to DNA at 3Å resolution(1) gave a structural view of the binding to a single GAAA core. However, the structural basis for the diverse binding properties of the IRF family members is largely uncharacterized.

Here, we have crystallized(2) and determined the crystal structure of a DNA binding domain of IRF-2 complexed with DNA whose sequence is designed to form a tandem repeat of the core sequence. The current model was refined to R-factor/Rfree 20.4% and 24.3%, respectively. The structure at higher resolution(2.2Å) established the detailed framework of DNA recognition, especially water-mediated interactions. Moreover, we found that AANNGAAA is the sequence physically recognized by IRF-2. The facts well explain the diverse binding properties of the IRF family members, which bind to both single and tandemly-repeated sequences. Our analysis also reveals DNA structural deformations, indicating a cooperative binding of IRFs to tandem repeats of the core sequence.

P07.04.046 STRUCTURAL ANALYSIS OF NUCLEIC ACID COMPLEXES WITH A CATALYTIC FRAGMENT OF REVERSE TRANSCRIPTASE. Shabir Najmudin, Dunming Sun, Marie Cote, and Millie Georgiadis, Waksman Institute, Dept. of Chem., Rutgers University, Piscataway, NJ

Reverse transcriptase is an essential retroviral enzyme that makes a double-stranded DNA copy from the single-stranded RNA genome of the retrovirus using RNA- and DNA-directed DNA polymerase activities and an RNaseH activity. We have determined high resolution structures of Moloney murine leukemia virus reverse transcriptase (MMLV RT) complexed with nucleic acid in three distinct crystal lattices. The catalytic fragment is comprised of the fingers and palm domains of RT and retains polymerase activity. Although retroviral RTs all perform similar functions, the architectures of the enzymes are quite different. MMLV RT is monomeric as isolated but has been proposed to form homodimers in the presence of nucleic acid, based on gel retardation results. HIV-1 RT and ASV RT, representing the other two observed architectures, are both heterodimeric with the second smaller subunit resulting from proteolytic processing of the larger subunit. Based on our crystallographic analysis, we have analyzed dimer formation and assessed its functional significance in MMLV RT.

Two crystal forms (Forms I and II) are monoclinic and include two catalytic fragment molecules and a single symmetric 8/8-mer DNA molecule in the asymmetric unit. The third crystal form is orthorhombic and has one catalytic fragment molecule and one DNA molecule (6/10-mer) in the asymmetric unit. The protein-DNA interactions are similar in each crystal. But, the crystal packing and protein-protein interactions differ significantly. In Form I crystals, the two molecules in the asymmetric unit have few protein-protein interactions. More significant protein interactions are found between two dimers in the crystal. In Form II crystals, the two molecules in the asymmetric unit form a homodimer. Interactions involve 16 residues from the A molecule and 15 residues from the B molecule burying 1,500 $Å^2$ of surface area. In a preliminary analysis of crystal packing interactions in the third crystal form, we have found significant and interesting differences.

P07.04.047 RESTRICTION ENDONUCLEASES BGL II VS. BAM HI: WHAT A DIFFERENCE A BASE MAKES. Christine M. Lukacs [1], Rebecca Kucera, Ira Schildkraut [2], Aneel K. Aggarwal [1], 1. Mount Sinai School of Medicine, Department of Physiology and Biophysics/Structural Biology, New York, NY, 2. New England Biolabs, Inc., Beverly, MA.

Extensive high-resolution crystallographic studies in our laboratories have delineated the atomic contacts made between the restriction endonuclease Bam HI and its target DNA site, and have shown its mechanism of action. [1-3] However, there is nothing obviously remarkable about these contacts, as compared to other DNA binding proteins, to rationalize the incredible specificity of restriction endonucleases for their target sites. In order to help further our understanding of this phenomenon, we have undertaken the structure determination of Bgl II, a restriction endonuclease of similar size to Bam HI, also functionally dimeric, whose symmetric recognition sequence differs from that of Bam HI by only one base pair – A|GATCT vs. G|GATCC – yet has a completely unrelated primary sequence. Bgl II complexed with a symmetric DNA 16-mer forms crystals in space group $P2_12_12_1$ which diffract beyond 2.0 Å resolution. Selenomethionine substituted protein and brominated oligonucleotide have provided good crystals for use in MAD experiments. Details of the

structure determination and a structural analysis of the complex will be presented.

P07.04.048 THE RUNT DOMAIN, A NOVEL DNA BINDING FOLD S. Bäckström, S.H. Huang [1], M. Wolf-Watz [2], U.H. Sauer [1], [1] Umeå Centre for Molecular Pathogenesis, Umeå University, S-901 87 Umeå, Sweden, [2] Dept. of Biotechnology, Royal Institute of Technology, Novum, S-141 57 Huddinge

The acute myeloid leukemia related protein AML1 or its hetero-dimerization partner CBFb are the most common cause for acute human leukemias. The evolutionary conserved Runt Homology Domain (RUNT domain) comprises the N-terminal 190 residues of AML1 which harbours both the DNA binding and hetero-dimerization activities. Recently is was shown, that dephosphorylation of AML1 by the Ca2+/Calmodulin dependent phosphatase Calcineurin (CN) activates AML1 by improving both its binding to CFBb and DNA [1].

The Runt domain might represent a new class of DNA binding protein folds as there is no sequence similarity to any structurally described DNA binding fold. Preliminary studies by NMR and secondary structure predictions suggests that the runt domain comprises six b-strands, two a-helices and a nucleotide binding motif [2].

We have collected synchrotron data to 1.7 Å resolution and will present structure of the RUNT domain in the presence of its cognate DNA.

P07.04.049 LOW SALT CRYSTAL STRUCTURES OF T7 RNA POLYMERASE AND ITS TRANSCRIPTION BUBBLE. C.-J. Chen[1,2], F. Schubot[1], Z.-J. Liu[1], J. P. Rose[1], and B.-C. Wang[1], [1]Department of Biochemistry and Molecular Biology, University of Georgia, Athens, GA 30602, U.S.A. [2]Department of Crystallography, University of Pittsburgh, Pittsburgh, PA 15260, U.S.A.

The flow of genetic information from DNA to protein is a two-step process, with RNA as an intermediate. DNA-dependent RNA polymerase is the key enzyme responsible for the biosynthesis of RNA, a process known as transcription. This process, which decodes the genetic information from DNA, with RNA as an intermediate, is one of the most significant events in a biological system.

Bacteriophage T7 RNA polymerase, a single peptide chain polymerase with a molecular weight of about 99kDa, was previously crystallized under high-salt conditions[1], however, these crystals were not suitable for the formation of DNA-RNA and RNAP complexes as the presence of salts reduces the binding affinity of DNA to RNAP. A search for low salt crystallization conditions has yielded a new low-salt crystal form of T7 RNA polymerase in a space group P3121, which also lead us to produce the crystals of T7 RNAP-DNA-RNA bubble complex in the same space group with the larger unit cell. The Electron density maps clearly show density of the appropriate dimensions of the DNA-RNA bubble duplex complexed with T7 RNAP. We report here the three-dimensional structure of T7 RNAP at 2.7 Å resolution and T7 RNAP DNA-RNA bubble complex at 4.0 Å resolution.

1. Sousa, R., Chung, Y.-J., Rose, J. P. and Wang, B.-C. (1993) The crystal Structure of Bacteriophage T7 RNA Polymerase at 3.3 Å resolution. Nature, 364, 593.

P07.04.050 PRELIMINARY CRYSTALLOGRAPHIC STUDIES OF THE YEAST MITOCHONDRIAL TRANSCRIPTION FACTOR, MTF1P. F. D. Schubot, C.-J. Chen, J.P. Rose, and B.-C. Wang, Department of Biochemistry and Molecular Biology, University of Georgia, Athens, Ga 30602, U.S.A.

Transcription in the mitochondria of Saccharomyces cerevisiae is carried out by a two subunit RNA polymerase[1]. The core enzyme, RPO41p, is a 153 kDa protein that shows strong homology with bacteriophage RNA polymerases. However, while these phage RNA polymerases do not require a co-factor for promoter recognition and initiation of transcription, RPO41p only recognizes its promoter in the presence of the s-like factor MTF1p (43kDa). The current model suggest that MTF1p, similar to s-factors such as s70 in E.coli., after association with the core enzyme binds to the promoter and targets the core enzyme to the initiation site[2].

Single crystals have been obtained for the mitochondrial transcription factor MTF1p. In low-temperature X-ray crystallographic studies these crystals diffracted beyond 3.0 Å. The protein crystallized in the monoclinic space group C2. The cell constants are a= 90.0 Å; b= 44.5 Å; c= 98.8 Å; There is one molecule in the asymmetric unit. The Rmerge is 5.5%.

P07.04.051 CRYSTAL STRUCTURE OF MOLECULAR CHAPERONE HSP40. Bingdong SHA, Department of Cell Biology, Univ. of Alabama at Birmingham, Birmingham, AL 35294-0005, USA

Heat-shock protein 70(Hsp70), one of the major molecular chaperones, has been shown to play a central role in many cellular processes. Heat-shock protein 40(Hsp40) works as a co-chaperone for Hsp70. Hsp40, bound by substrate, can interact directly with Hsp70 to stimulate the ATPase activity of Hsp70. Hsp40 can also bind to unfolded polypeptide and prevent them from aggregation *in vitro* as an independent molecular chaperone.Hsp40/Hsp70 system is highly involved in many cellular functions such as protein biosynthesis and degradation, protein trafficking, steroid signal transduction. *S. cerevisiae* Hsp40 Sis1 C-terminal peptide-binding domain has been determined by X-ray crystallography.

P07.04.052 THE THREE-DIMENSIONAL STRUCTURE OF THE RNA-BINDING DOMAIN OF RIBOSOMAL PROTEIN L2. Isao Tanaka, Atsushi Nakagawa, Masae Taniguchi and Harumi Hosaka. Division of Biological Sciences, Graduate School of Science, Hokkaido University, Sapporo 060-0810, Japan. Takashi Nakashima, and Makoto Kimura. Laboratory of Biochemistry, Faculty of Agriculture, Kyushu University, Fukuoka 812-8512, Japan

In all living cells, protein synthesis is carried out in cellular organelles called ribosomes. These large ribonucleoprotein complexes are generally organized in two subunits of unequal size. In prokaryotic *Escherichia coli* ribosomes, the large (50S) subunit consists of 34 proteins and 5S

and 23S rRNAs, while the small (30S) subunit is a complex of 21 proteins and 16S rRNA. Ribosomal protein L2 is the largest protein component in the ribosome. It is located at or near the peptidyl transferase center and has been a prime candidate for the peptidyl transferase activity. It binds directly to 23S rRNA and plays a crucial role in its assembly. The three dimensional structure of the RNA-binding domain of L2 from *Bacillus stearothermophilus* has been determined at 2.3Å resolution by X-ray crystallography using the Se-Met MAD method. The RNA-binding domain of L2 consists of two recurring motifs of about 70 residues each. The N-terminal half domain (pos. 60 - 130) is homologous to the OB-fold and the C-terminal half (pos. 131 - 201) is homologous to the SH3-like barrel. Both structure motifs are often found in RNA- or DNA-binding proteins, and their RNA-binding sites have been predicted to be regions constructed by the loops protruding outward from the barrel axis. The residues Arg86 and Arg155, which have been identified by mutation experiments to be involved in the 23S rRNA binding, are located on the protruding loops at the gate of the interface region between the two domains. *Bst*L2-RBD appears to bind the target RNA on the cleft formed by the N- and C-terminal domains, which probably confers on protein L2 a specific recognition for the target RNA. The molecular architecture suggests how this important protein has evolved from the ancient nucleic acid binding proteins to create a 23S rRNA-binding domain in the very remote past.

P07.04.053 CRYSTALLIZATION OF rRNA APTAMER BINDING WITH THE RIBOSOMAL PROTEIN S8. N. Davydova and A. Liljas, Molecular Biophysics, Lund University, POB 124, S-221 00 Lund, Sweden, H. Moine, B. Ehresmann and Ch. Ehresmann, UPR 9002, Institute for Molecular and Cellular Biology, 67084 Strasbourg, France, and Maria Garber, Institute of Protein Research, 142292 Pushchino, Moscow Region, Russia.

Ribosomal protein S8 plays a key role in 30S ribosomal subunit assembly through interaction with 16S rRNA. Its binding site consists of two base paired helical regions that flank a phylogenetically conserved core element containing 9-13 nucleotides. Recently the solution structure of S8 binding rRNA fragment from *Escherichia coli* has been defined using NMR spectroscopy (1), and the crystal structures of S8 protein from *Bacillus stearothermophilus* (2) and *Thermus thermophilus* (3) have been determined. Some conclusions about the importance of different RNA residues for S8-RNA binding were presented in these publications. However there are still many questions which could be solved by crystal structure of the RNA fragment itself and in complex with the protein.

In Selex experiments S8 binding RNA aptamers from *T. thermophilus* with different changes in core region were obtained (4). After search for crystallization conditions for RNA aptamers, one of them was crystallized in the present work. The attempts to crystallize wild type rRNA fragment were unsuccessful.

The native data set was collected at beamline BL711 at MAXII synchrotron in Lund. Crystals diffract to 2.9 Å resolution. The space group of observed crystals was found to be P1, with cell dimensions a=30.17 Å, b=45.65 Å, c=100.82 Å, α=93.47°, β=95.04°, γ=102.71° and four molecules in the asymmetric unit. These values correspond to V_m (volume of asymmetric unit/molecular weight) of 2.39 Å^3/Da, which is in the range usually found for RNA crystals. Heavy atom derivatives search is in progress.

P07.04.054 TOWARDS A NEW CRYSTAL FORM OF BACTERIOPHAGE MS2 COAT PROTEIN. W.T. Horn, M.A. Convery, N.J. Stonehouse, P.G. Stockley and S.E.V. Phillips, Faculty of Biological Sciences, University of Leeds, Leeds, LS2 9JT, UK.

MS2 is a T=3 icosahedral bacteriophage with a single stranded RNA genome that infects *E. coli. In vivo* an RNA stem loop binds to a phage protein coat dimer, acting both to initiate phage self assembly and to inhibit viral replicase gene translation. Structures of the MS2 phage particle and both wild type[1] and aptamer[2] stem loops bound to MS2 capsids have been determined.

It has been demonstrated that the MS2 coat protein can be used as a supramolecular scaffold to anchor small RNA motifs covalently bound to the stem loop sequences, thus allowing their structural determination. Using this system it is no longer necessary to search for individual crystallisation conditions for each RNA.

In vivo, RNA is stabilised by interactions with metal ions and therefore their presence is important to ensure the RNA structure determined is of biological relevance. However, current crystallisation conditions for MS2 utilise a sodium phosphate buffer which leads to precipitate formation on addition of metal ions.

One possible solution is to carry out MS2 crystallisation under different conditions. Trials are currently being undertaken and several of the crystal types obtained are being characterised.

P07.04.055 STRUCTURE AND FUNCTION STUDIES OF POLY(A) POLYMERASE FROM S. CEREVISIAE. N.C. Picken[1], W. Keller[2], J. Jäger[1]. [1]School of Biochemistry and Molecular Biology, University of Leeds, Leeds, UK, LS2 9JT. [2]Dept. Cell Biology, Biozentrum, University of Basel, Basel Switzerland.

Poly(A) polymerase (PAP) is involved in the maturation of pre-mRNAs. Poly(A) tails are found on essentially all mRNAs and have a variety of different functions such as control of mRNA turnover and translation efficiency. In order to gain an understanding of this enzyme it is desirable to determine its crystal structure.

Yeast PAP has been chosen for structural studies. This has a shorter amino acid sequence and is assumed to be a more compact enzyme and therefore more suitable for crystallisation experiments. With 58% overall sequence homology to its mammalian counterparts the structure of Yeast PAP could also provide information about these enzymes.

Light scattering experiments have been carried out using PAP from *S. cerevisiae* and *S. pombe*. Both His-tagged and untagged samples were used and the results showed that PAP is monomeric and is monodisperse and would therefore appear suitable for crystallisation experiments.

Previous crystallisation experiments have resulted in initial conditions which gave rise to small rod shape crystals. However these diffracted poorly, to around 8Å under cryo-conditions, and further crystallisation experiments are being carried out to produce better diffracting crystals.

P07.04.056 3D STRUCTURE OF THE TATA-BOX BINDING PROTEIN FROM A THERMOPHILI-CARCHAEBACTERIUM, *SULFOLOBUS ACIDOCALDARIUS*. Hideaki Koike[1], Norio Kudo[1,2], Yoshie Kawashima[1], Masaru Tateno[1], Kazuhiko Yamasaki[1] and Masashi Suzuki[1,2] ([1]AIST-NIBHT CREST Centre of Structural Biology, [2]Graduate School of Human and Environmental Sciences, University of Tokyo)

The 3D structure of the TATA-box binding protein (TBP) from a thermophilic archaebacterium, *Sulfolobus acidocaldarius*, has been determined in the resolution of 2.7Å with the R-factor being 26.6%. Crystals of the TBP were obtained by the vapour diffusion method using sulfate salts as precipitants. The crystal was identified to be of the orthorhombic space group, P21212, and thus is different from any other reported crsytals of TBPs. Two independent molecules were identified positioning in the asymmetric unit of 64.0x81.2x88.1 Å. A 3D model was constructed by replacing amino acid side-chains in the crystal structure of TBP of another species (1PCZ), and modified by energy minimization. In order to produce best agreement with the crystallographic data, the inter-domainal connection in the model was changed systematically while keeping the domainal structures intact, and then the co-ordinates of each atom in the domains were changed. The process was repeated until the best R-factor and freeR values were recorded. In the final structure the overall combination of the secondary structures was found essentially kept the same, but differences in position and conformation were observed in the residues in distal region from the centre of the molecules and loops connecting the region and the central β-strand. On the basis of the determined TBP structure and known TBP structures of other species, and of the amino acid sequences of TBPs of archabacterial species that possess different optimal growth temperature values, the domainal thermostability and the inter-domainal thermal flexibility are being studied. The TBP of a hypr-thermophilic archaebacterium, *Pyrococcus* sp. OT3 (Opt. T., close to 100°C) is, in general, more stable than TBPs of two thermophilic archaebacterial species, *Sulfolobus acidocaldarius* (Opt. T., 75°C), and *Thermoplasma volcanium* (Opt. T., 60°C). The TBP from *Thermoplasma* showed higher thermal stability upon decreasing the KCl concentration, while the other two TBPs, in contrast, upon increasing the KCl concentration. Specific amino acid residues and more global factors that determine the thermostability and its salt dependence are being investigated. An amino acid position that is possibly important for the thermal flexibility has been identified on the inter-domainal surface, which is occupied by a large aromatic residue, Phe, in the TBP from *Pyrococcus*, and a small residue, Ala, in that from *Thermoplasma* and *Sulfolobus*, while the smallest residue, Gly, in those of the eukaryotic origin.

P07.04.057 CRYSTALLOGRAPHIC STUDIES OF HISTONE-LIKE SUBUNITS OF TFIID. S. Werten, C. Romier, C. Birck, O.Poch, M. Ruff, G. Mengus, A.C. Lavigne, I. Davison, D. Moras IGBMC, Illkirch, France.

Transcription initiation in eukaryotes by RNA polymerase II requires the assembly of a macromolecular complex at the core promoter of a gene. The multi-subunit factor TFIID plays a key role in the formation of this complex, as it recognizes the core promoter DNA and is the interaction target for many transcriptional activators. TFIID is composed of the TATA-binding protein (TBP) and a number of TBP-associated factors (TAFIIs). Recently, some of the TAFIIs have also been found in other macromolecular complexes (hTFTC, ySAGA and hPCAF) that are involved in transcription. Three of the TAFIIs - hTAFII80, hTAFII31 and hTAFII20 - display strong similarity, both in sequence and structure, to histones H4, H3 and H2B, respectively. Consequently, TFIID has been proposed to contain a nucleosome-like core, consisting of two H2A/H2B-like homodimers of hTAFII20 and a H3/H4-like heterotetramer of hTAFII80 and hTAFII31. A similar core structure could exist in hTFTC, ySAGA and hPCAF. However, this model does not address the role of the additional TAFIIs that are found in TFIID. We have therefore started the structural study of other subcomplexes within TFIID. This work has recently led to the determination of the structure of the complex formed by hTAFII18 and hTAFII28. Although the full-length proteins were used for crystallization, crystals contained truncated polypeptides due to proteolysis within the crystallization droplet. The crystals belong to space group $P2_12_12_1$ with a=45.4, b=48.4 and c=77.6 Å. The structure was solved by using exclusively anomalous data from crystals soaked with pCMBS that showed a decrease of 7 Å in the c-axis compared to the native crystals. The mercury-bound structure was refined at a resolution of 2.6 Å and was then used to solve the native structure by molecular replacement. This latter structure was refined at 3 Å and showed no real difference with the mercury-bound one. Unexpectedly, the two proteins were found to interact through histone folds, which cannot be classified within the four canonical families (H2A/B, H3, H4). Sequence analysis revealed that the protein SPT3, found in the TFTC, SAGA and PCAF complexes, contains at its N- and C-termini two histone fold motifs which are strongly homologous to the histone fold motifs of hTAFII18 and hTAFII28, respectively. Since both hTAFII18 and hTAFII28 are absent from TFTC, SAGA and PCAF, SPT3 may be the structural equivalent in these complexes of the two TAFIIs in TFIID.

P07.04.058 MACROMOLECULAR CRYSTALS : A QUESTION OF INTERACTION POTENTIALS. F. Bonneté, A. Le Verge, S. Finet and A. Tardieu, LMCP, CNRS - Universités Paris VI et Paris VII, 4 Place Jussieu, 75252 Paris Cedex 05, France; L. Belloni, SCM, DRECAM, CE Saclay, 91191 Gif sur Yvette Cedex, France.

Biological macromolecules in solution interact with each other through medium range (from a few Å to a few nm) interaction potentials. These potentials control the macromolecular distribution in solution, the macromolecular phase diagram and the crystallization process. We have shown previously that Small Angle X-ray Scattering (SAXS) is a convenient tool to characterize the resulting potential, either attractive or repulsive, and to follow the changes induced by the crystallizing agents (1). The approach, applied to lysozyme crystallization, demonstrated that protein interactions are involved and not agregation, and that particle are in the attractive regime (2). In the present study, simulation methods derived from statistical mechanics were coupled to SAXS to find out the best fit potentials able to account for the experimental lysozyme SAXS data.

The currently used models in the colloidal field are derived from the DLVO (Derjaguin, Landau, Verwey, Overbek) potential where three types of interactions play a major role : hard sphere, electrostatic, van der Waals. In a series of X-ray experiments, the best fit parameters to determine from the shape of the scattering curves are the hard core diameter and the depth and range for both the repulsive and the attractive contribution to the resulting potential. The attractive potential at the isoelectric point was found to be short range (i.e. between zero and 6 Å) as already found for gamma-crystallins (3), and equivalent to an adhesive sphere potential. Decreasing the pH at low ionic strength introduces a repulsive coulombic component which can be screened by salt. To account for the anion specificity on lysozyme crystallization, following the reverse order of the Hofmeister series, some modifications of these potentials are, however, required.

The whole of the data demonstrate that the colloidal approach may be applied with success to lysozyme crystallization.

P07.04.059 A NEW CRYSTAL STRUCTURE FOR THE DNA SEQUENCE d(CGCGAATTCGCG). GN Parkinson, EM Johansson and S Neidle, The CRC Biomolecular Structure Unit, The Institute of Cancer Research, Sutton, Surrey SM2 5NG, UK

The DNA sequence d(CGCGAATTCGCG) has been the subject of intensive study following on from its original crystallographic analysis by Dickerson and Drew. In particular, the features of sequence-dependent structure and minor-groove hydration first described in the original structure have been taken as the paradigm for DNA flexibility and hydration. However there continues to be controversy surrounding the role played by crystal packing forces in producing these effects.

We have solved the crystal structure of d(CGCGAATTCGCG) in the hitherto unreported space group $P3_212$, with cell dimensions a = b = 26.39 Å and c = 98.78 Å. Crystals were obtained in the presence of Ba^{2+}, and diffraction data has been collected to 1.8 Å on beam line 9.5 at the Daresbury Synchrotron source. The structure has been solved by molecular replacement, using a decamer as the search fragment, and refined by X-PLOR. Uniquely for a native DNA dodecamer, the duplex formed has crystallographic 2-fold symmetry, and the asymmetric unit is a single strand of d(CGCGAATTCGCG). The sequence-dependent and hydration features of this structure will be presented in detail.

P07.04.060 FIRST HIGH RESOLUTION STRUCTURE OF AN RNA FRAGMENT FROM MAMMALIAN SRP RNA. Klemens Wild, Oliver Weichenrieder & Stephen Cusack: EMBL Grenoble Outstation, France.

The mammalian Signal Recognition Particle (SRP) is an 11S cytoplasmic ribonucleoprotein complex consisting of the SRP RNA (300 nt) and six proteins. SRP mediates the cotranslational targeting of secretory proteins to the translocation apparatus in the endoplasmatic reticulum membrane.

We have crystallized and solved the structure at 2.0 Å resolution of an RNA fragment comprising 29 nt of helix 6 of mammalian SRP, the principal binding site of SRP19. The structure was solved by the MAD method using the anomalous signal from Br-U which was incorporated into the RNA via an *in vitro* transcription. Clean RNA 3' ends were generated by ribozyme technology. Due to the intolerance of the ribozyme active site for Br-U, the maximum occupancy of Br-U in the molecule had to limited to 50%.

Instead of forming a monomeric hairpin structure with a GGAG tetraloop, in the crystal the RNA forms 28-mer duplexes with distorted A-RNA geometry and the overhanging base being flipped out. Duplex formation is a general problem in the crystallization of RNA hairpins. Aligning parallel to the crystallographic 3-fold axis, the duplexes give rise to infinite helices thus forcing the previously formed hairpin to open up. Despite the dimerization, 24 out of the 28 base pairs represent the presumed native structure with only the tetraloop forming an artificial 5'-GGAG-3'/3'-GGAG-5' purin bulge containing an internal GA tandem mismatch. The irregularities of the native part of the structure include a 5'-AC-3'/3'-CA-5' tandem mismatch with protonated and non-protonated adenine bases and GU wobble base pairs. Moreover, the crystal packing creates a 5'-GU-3'/3'-GU-5' tandem wobble base pair forming a cross strand purin stack. The high resolution allows a detailed analysis of the model including magnesium and water moelcules. The native structure containing the SRP RNA specific GNAR tetraloop is modeled using the well-known GNRA hairpin fold.

P07.04.061 CRYSTAL STRUCTURE OF A COMPLEX BETWEEN THE SEQUENCE d(CGCGAATTCGCG) AND A NOVEL MINOR-GROOVE DRUG. EM Johansson, GN Parkinson, J Mann[1] and S Neidle, The CRC Biomolecular Structure Unit, The Institute of Cancer Research, Sutton, Surrey SM2 5NG, UK and [1]Dept of Chemistry, University of Reading, Berkshire RG6 6AH, UK

The crystal structures of over 25 complexes between minor groove drugs and DNA oligonucleotide sequences have now been solved in this laboratory. We have recently embarked on the design of novel minor-groove ligands, exploiting this knowledge-base, with special reference to the roles played by hydrogen-bonding and van der Waals forces in defining sequence-specificity. One such series is based on a head-to-head arrangement for two bis-benzimidazole rings (Neidle et al, Chem. Comm, 1999, in press).

We now report the crystal-structure analysis of a complex between the sequence d(CGCGAATTCGCG) and a symmetric head-to-head bis-benzimidazole with substituent propyl-dimethylamino side-chains. The structure crystallises in the space group $P2_12_12_1$, with cell dimensions a = 25.145, b = 39.924 and c = 65.648 Å. Intensity data were collected on a flash-frozen crystal at 100 K to a resolution of 2.0 Å. The structure is isomorphous with other dodecamer complexes; it has been refined by XPLOR and SHELX-97. The current R and R_{free} values are 0.20 and 0.28 respectively, with > 100 water molecules and a hydrated magnesium ion having been located.

The drug is symmetrically bound in the minor groove, with the benzimidazole groups hydrogen bonding to A:T base pairs. The side-chains are not hydrogen-bonded, but are held more loosely in the wider G:C minor groove regions.

P07.04.062 STRUCTURE OF MUTANT TEF1W OF THE SRC SH2 DOMAIN COMPLEXED WITH PHOSPHOTYROSINE CONTAINING PEPTIDES. Joseph Nachman, Matthew Kimber, Annie Cunningham, and Emil Pai, Ontario Cancer Institute and Department of Biochemistry, University of Toronto, Toronto, Ontario M5S 1A8, Canada; Gerald Gish and Antony Pawson, Samuel Lunenfenld Research Institute, Mount Sinai Hospital, Toronto, Ontario M5G 1X5, Canada.

A common device through which receptor tyrosine kinases access their intracellular targets involves receptor autophosphorylation at Tyr sites, which consequently bind the Src homology 2 (SH2) domains of cytoplasmic signaling proteins. The affinities with which SH2 domains bind to phosphorylated peptide motifs generally depends on the sequence of amino acids immediately C-terminal to the phosphotyrosine. It has previously been shown that changing a single amino acid at the EF1 position of the Src SH2 domain from Thr to Trp converts its binding specificity to resemble that of the Grb2 SH2 domain, and that this mutant Src SH2 domain functions *in vivo* during *C. elegans* development in place of the Grb2 (SEM-5) SH2 domain. We have solved the X-ray crystal structure of the mutant TEF1W Src SH2 domain in complex with phosphopeptides (pYEEI and pYVNV) that normally bind preferentially to Src or Grb2 domains, respectively. The presence of Trp at the EF1 position blocks the normal path of pYEEI peptide bound to the mutant Src SH2 domain, but readily accommodates a pYVNV peptide. The conformations of the pYVNV peptide bound to the mutant Src SH2 domain and the Grb2 SH2 domain are virtually identical. Our results strikingly illustrate how SH2 domains distinguish between different phosphorylated sites, and suggest a mechanism through which simple substitutions could allow for rapid evolution of SH2

domain specificity, and thus for increased complexity in pTyr signaling.

P08.04.001 SERINE PROTEASES INTERACTIONS WITH ECOTIN: A GENERAL SERINE PROTEASE INHIBITOR FROM E. COLI. Stephanie Wang [1], Sarah Gillmor [2], Charles Craik [3], Robert Fletterick [4], [1,3] Department of Pharmaceutical Chemistry, [2] Program in Biophysics, [3,4] Department of Biochemistry and Biophysics, University of California at San Francisco, CA 94143, U.S.A.

Protease activities are found to be associated with various biological processes. Many small or macromolecular inhibitor have found in nature. Understanding the interactions between proteases and their macromolecular inhibitors provides many insights for elucidating the mechanism of protease actions as well as for designing new inhibitors which may be of therapeutic significance. Ecotin, a macromolecular inhibitor discovered from E. Coli. periplasm, has the unusual property of inhibiting a variety of serine proteases regardless of their substrate specificity. Crystal structures of complexes of ecotin-rat trypsin and ecotin-crab collagenase revealed novel tetrameric complexes formation. Each complex contains two ecotin and two protease molecules. Each ecotin molecule contacts two protease molecules at two different binding sites. How does ecotin interact with its cognate proteases at the different binding sites? Can we engineer ecotin to alter its inhibitory profile against various cognate proteases or to create novel inhibitory activities against non-cognate proteases?

To elucidate the details of interactions between ecotin and its cognate serine proteases, we are solving the structures of complexes between rat trypsin and ecotin variants with different mutations at the protease binding sites. Structures of complexes between rat trypsin and four different ecotin variants have been determined by X-ray crystallography. Diffraction data have been collected for a fifth complex. The structure is currently being solved. Crystallisation experiments are being carried for several other complexes between rat trypsin and ecotin mutants. Extensive comparison studies of the structures of these complexes will help us to understand the interactions between ecotin and rat trypsin, one of its cognate serine proteases.

Wild type ecotin fails to inhibit thrombin, a serine protease which shares high sequence and structural homology with rat trypsin. However, a single mutation in ecotin turns it into a moderate inhibitor against thrombin. We are investigating possible structural changes which allow this drastic change of inhibitory profile by determining the crystal structure of the complex between thrombin and the ecotin mutant. Initial studies have resulted in crystals which diffracted to 3Å. Crystallisation conditions are being optimized for better quality crystals which will give higher resolution data.

The interactions between ecotin and different serine proteases provide knowledge for understanding basic protein-protein interactions. Such knowledge we gain here will also serve as basis for designing novel inhibitors against targets such as viral proteases.

P08.04.002 THE LOSS OF HYDROPHOBIC CORE PACKING INTERACTIONS IS STRONGLY CORRELATED TO THE LOSS OF PROTEIN STABILITY. M. Vlassi, NCSR "Demokritos, Ag. Paraskevi, GR-15130 Athens, Greece, G. Cesareni, Dipartimento Di Biologia, Tor Vergata, Il Universita degli Studi di Roma, Rome, Italy and M. Kokkinidis, Department of Biology, University of Crete, & Institute of Molecular Biology and Biotechnology, GR-71110 Heraklion, Crete, Greece.

Globular proteins are characterized by well-packed hydrophobic cores which play important roles in protein folding and stability. The small homodimeric ROP protein follows the 4-α-helical bundle structural motif and its folding and stability are largely determined by a regular pattern of hydrophobic core interactions [1]. In order to examine structural and thermodynamic responses to core mutations in proteins, the crystal structures of two large-to-small (Leu→Val/Ala) substitutions of the core residue Leu41 of the ROP protein have been determined.

Both substitutions are destabilizing [2] and lead to formation of cavities. The main responses to mutations are the collapse of the central part of the alpha-helix containing the site of mutation, shifts of internal water molecules, and in L41A, the trapping of a water molecule in the cavity created by the mutation. These effects counteract the increase in cavity size, so that the actual cavities are much smaller than what would be expected in the absence of the above effects.

A new parameter (Δn_h) is introduced as a measure of the number of Van der Waals contacts lost. For ROP, barnase and T4 lysozyme mutants there is a good correlation between Δn_h and the free energy of unfolding $\Delta\Delta G$ relative to wild-type protein. The Δn_h turns out to be more suitable for analysing structural and energetic responses to mutation than other parameters, such as cavity volumes and packing densities.

P08.04.003 STRUCTURAL STUDIES OF UBIQUINONE BINDING SITES IN BACTERIAL PHOTOSYNTHETIC REACTION CENTRES. P.K. Fyfe*, J.P. Ridge and M.R. Jones* Department of Molecular Biology and Biotechnology, Krebbs Institute, Firth Court, University of Sheffield, Western Bank, Sheffield, S10 2UH. U.K. and K.E. McAuley-Hecht, R.J. Cogdell Department of Biochemistry and N.W. Isaacs, Department of Chemistry, University of Glasgow, University Avenue, Glasgow, G12 8QQ. U.K. *Current Address: Department of Biochemistry, School of Medical Sciences, University of Bristol, University Walk, Bristol, BS8 1TD. U.K.

Several crystal structures of the bacterial photosynthetic reaction centre from *Rhodopseudomonas viridis* and *Rhodobacter sphaeroides* are now available [1,2]. The availability of these structures has greatly enhanced our understanding of how these integral membrane pigment:protein complexes function, and has allowed the rational design of site-directed mutants to probe structure/function relationships within the complex. X-ray crystallography is now also being applied to the mutant complexes themselves, with several crystal models revealing hitherto unexpected structural arrangements. This presentation will discuss the results of studies of several complexes bearing mutations in one of the two ubiquinone binding sites, and in particular a 2.1Å model of a Q_A minus mutant complex (AM260W) which showed very high occupancy of the Q_B binding site. There has recently been much debate in the field as to the position assumed by the Q_B cofactor in the native complex, with early crystal models showing only very poor occupancy of this site. More recently two groups have made use of reconstitution with quinones and/or chemical analogues to attempt to overcome this problem [1,2]. The AM260W crystal structure gives the first well resolved model of the site in a complex which has not been chemically treated to obtain the high occupancy.

P08.04.004 SPECIFIC BINDING OF CARDIOLIPIN TO AN INTEGRAL MEMBRANE PROTEIN. K.E. McAuley, K. McKendrick, R.J. Cogdell, Department of Biochemistry and N.W. Isaacs, Department of Chemistry, University of Glasgow, Glasgow G12 8QQ, UK and P.K. Fyfe*, J.P Ridge and M.R. Jones*, Department of Molecular Biology and Biotechnology, Krebbs Institute, Firth Court, University of Sheffield, Western Bank, Sheffield, S10 2UH. U.K.

*Current Address: Department of Biochemistry, School of Medical Sciences, University of Bristol, University Walk, Bristol, BS8 1TD

Cardiolipins are an important class of anionic phospholipid. Cardiolipin has been shown to have a regulatory role in the activity of a number of integral membrane proteins [1-3] e.g. cytochrome *c* oxidase which has an absolute requirement for cardiolipin for function [4]. Despite the fact that extensive study has been made of the role of anionic lipids in biomembrane function, relatively little is known about the molecular details of the interactions between these lipids and the proteins to which they bind. Recently, we determined the structure of a mutant photosynthetic reaction centre with a bound cardiolipin molecule. The lipid binds to the surface of the protein, with interactions between the phosphate headgroup of the lipid and arginine/histidine residues of the protein. There are also extensive van der Waals interactions between the acyl chains of the lipid and grooves on the protein surface. Based on the analysis of this structure, several mutant complexes have been made to study the effect of cardiolipin on the function of this membrane protein.

P08.04.005 CRYSTAL STRUCTURE OF THE MUTANT F99S/M153T/V163A OF THE GREEN FLUORESCENT PROTEIN. R.Battistutta, A. Negro and G. Zanotti, Dipartimento di Chimica Organica, Centro Studi sui Biopolimeri and Dipartimento di Chimica Biologica, Università degli Studi di Padova, 35131 Padova, Italy.

The Green Fluorescent Protein from the jellyfish *Aequorea victoria* is a single domain protein of 238 aminoacids, that converts blue radiation into green light. GFP is characterized by the presence of a chromophore that originates from a post-translational autocatalitic cyclization of the tripeptide segment -S65-Y66-G67-, with successive dehydrogenation of the α-β bond of the tyrosine. In the mature protein the chromophore exhibits two characteristic absorption bands, at 395 nm and at 475 nm, and emits green light with an emission maximum around 508 nm. Due to its intrinsic fluorescence properties, GFP is widely used as fluorescent probe in several biotechnological applications. In the last three years, structures of wild-type GFP and of several mutants have been solved. By DNA shuffling techniques, the mutant F99S/M153T/V163A (GFP-sta) was found to be around 42-fold more fluorescent *in vivo* than the wt-GFP [1]. GFP-sta was crystallised in the tetragonal space group $P2_12_12_1$, and the structure was solved with the molecular replacement method. While the topology and the overall structure of the GFP-sta is similar to the other Green Fluorescent Proteins, nevertheless same interesting and peculiar features are present in our mutant. The two dimers in the asymmetric unit are not identical, particularly as far as the environment of the chromophore is concerned. In two chains the conformation of the side chain of Thr203 allows an hydrogen bond between the OH of this residue and that of the chromophore in absence of any water molecule. On the ground of the results presented here, we propose that the increase in the cell content of mature fluorescent protein is due to a more efficient folding process *in vivo* of the GFP-sta mutant.

P08.04.006 STUDY ON CARBOXYL-TERMINAL MODIFIED THERMOSTABLE 3-ISOPROPYLMALATE DEHYDROGENASE STRUCTURE. Z. Nurachman, S. Akanuma,[1] T. Oshima,[2] and N. Tanaka; Dept. Life Sci., TITech., Yokohama 226, Japan; [1]) RIKEN, Wako 351, Japan; [2]) Dept. Molec. Biol., Tokyo Univ. of Pharm. and Life Sci., Hachioji 192, Japan.

To understand the role of amino acid sequences at carboxyl terminus in maintaining thermostability, mutant structure of 3-Isopropylmalate dehydrogenase (IPMDH) of *Thermus thermophilus* has been solved. Advanced study on the improvement of thermostability for IPMDH was performed by creating mutants such as tandem sequence duplication mutants at C-terminus region , named HD177, HD708, and HD711 (Fig. 1.) (1). The α-helix at C-terminus of HD177 and HD708 is short. However, it is conserved in HD711. The thermostability of the mutants is lower than that of A172L. However, the protein is more thermostable, more elongated. The molecular model evidence shows that the side chains of A342 and F343 position of HD711 are located on unfavorable ionic region and the side chain of E341 is situated on adverse hydrophobic pocket. These interactions loose a tightness of structures at C-terminal region and reduce its thermostability. In addition, the hydrophobic extended sequences at C-terminus, which is exposed to solvent region, contribute weakening the structure. These phenomena imply that the interactions stabilizing the α-helix at C-terminus might have important role in regulation of thermophilic property. The function of these interactions has analogy with screw function in scissors. If they tighten or loosen, it could regulate the enzyme thermostability up or down without changing a significant catalytic constant.

P08.04.007 RELATIONSHIPS BETWEEN STRUCTURE AND STABILITY IN MUTANT HUMAN LYSOZYMES. Yuriko Yamagata, Graduate School of Pharmaceutical Sciences, Osaka University, Suita 565-0871, Japan and Jun Funahashi, Kazufumi Takano and Katsuhide Yutani, Institute for Protein Research, Osaka University, Suita 565-0871, Japan

Today we are in the era of structural genomics. When almost all protein folds are known, information about protein stabilization mechanisms will be useful for fold assignment and comparative protein structure modeling. To elucidate correlative relationships between structural change and thermodynamic stability in proteins, we have constructed about 100 mutant human lysozymes and determined their thermodynamic parameters of denaturation and crystal structures using differential scanning calorimetry and X-ray crystallography, respectively. Analyzing data base of stability/structure for mutant human lysozymes, we

have found that changes in stability due to amino acid substitutions are interpreted as the sum of changes in overall hydrophobic effect, side-chain conformational entropy, hydrogen bonds, the number of buried water molecules, cavity volume, secondary structure propensity and other effects (1, 2 and Funahashi et al. and Takano et al., submitted). The magnitudes of the contribution of these factors to protein stability have been estimated as the function of structural parameters using data of about 55 mutants with negligible other effects. For example, the change of hydrophobic effect is evaluated as the sum of 0.178ΔΔASA(non-polar) and –0.013ΔΔASA(polar), where ΔΔASA(non-polar) and ΔΔASA(polar) represent the difference in ΔASA of non-polar and polar atoms of all residues in a protein, respectively, upon denaturation between the wild-type and mutant proteins. These relationships between structure and stability can be used as monitors for the validity of fold assignment and comparative protein structure modeling.

P08.04.008 STABILITY OF A JELLYROLL FOLD: CRYSTAL STRUCTURE OF THE *BACILLUS* HYBRID ENZYME GLUXYN-1. J. Aÿ [(1)], F. Götz [(2)], R. Borriss [(2)] and U. Heinemann [(3)], (1) Institut für Biochemie der Charité, Humboldt-Universität, Monbijoustr.2, 10117 Berlin, Germany. (2) Institut für Biologie, Humboldt-Universität, Chausseestr.117, 10115 Berlin, Germany. (3) Forschungsgruppe Kristallographie, Max-Delbrück-Centrum für Molekulare Medizin, Robert-Rössle-Str.10, 13122 Berlin, Germany

Protein folding is a very interesting feature to understand more about the biological role of proteins in a cell. Former crystal structures of circularly permuted 1,3-1,4-β-glucanases [1,2] showed, that the jellyroll fold is a highly stable structure motif. As a consequence of our work about the stability of the jellyroll fold we designed the bifunctional *Bacillus* hybrid enzyme GluXyn-1. To construct GluXyn-1 two jellyroll proteins, the 1,3-1,4-β-glucanase of *Bacillus macerans* and the 1,4-β-xylanase of *B. subtilis* were joined by insertion of the entire domain XYN into the cpMAC-59, the circularly permuted variant of the wtGLU. The insertion protein generated by protein engineering folds into a stable protein and shows a comparable activity to the parental proteins [3]. The crystal structure of the two domain protein was determined at 2.1 Å resolution and refined to a R = 17.7 % and R(free) = 22.4 %. The structure is comparable to the crystal structure of the parental enzymes. The jellyroll fold of both domains survive and tolerate the insertion of an autonomous folding domain. There is a significant hinge bending between the domains. Both active sites are independent to each other, thus explaining the observed enzymatic activity. The results show that the protein folding for a jellyroll protein depends on long ranging intramolecular contacts in the sequence. Additionally there is a new way to build stable end-to-end fusion proteins.

P08.04.009 STRUCTURAL STUDIES OF A PHOTOSYNTHETIC REACTION CENTRE HYDROGEN BONDING MUTANT. K.A. McKendrick, K.E. McAuley-Hecht, R.J. Cogdell, Department of Biochemistry and N.W. Isaacs, Department of Chemistry, University of Glasgow, University Avenue, Glasgow, G12 8QQ UK and P.K. Fyfe*, D. Spiedel and M.R. Jones* Department of Molecular Biology and Biotechnology, Krebbs Institute, Firth Court, University of Sheffield, Western Bank, Sheffield, S10 2UH UK *Current address: Department of Biochemistry, School of Medical Sciences, University of Bristol, University Walk, Bristol, BS8 1TD.

Structural and functional studies on site-directed mutants of the photosynthetic reaction centre (RC) from *Rhodobacter sphaeroides* have been important in increasing our understanding of how this integral membrane protein-cofactor complex functions. This presentation will discuss one of several complexes in which the hydrogen bonding state of the primary donor (P) a bacteriochlorophyll dimer, has been altered. In the wild-type complex P has one hydrogen bond [1,2]. The mutant HL168F was designed to break this H-bond and spectroscopic evidence indicates that this is the case[3]. The FT-Raman spectrum of wild type RC contains a band at 1620cm^{-1}, assigned to this H-bond. This is completely absent in the mutant. The optical spectrum of the mutant is similar to that of the wild type complex with the exception that the P* (reduced P) absorption band is blue-shifted [1,2]. This has previously been suggested to be due to out of plane rotation of the P_L C2-acetyl . Diffraction data on this mutant was collected to 2.6 Å and is currently under refinement. The results of the crystallographic study will be discussed in this presentation.

P08.04.010 BURIED CHARGE IN PROTEINS: HYDROPHOBIC MUTATIONS IN MUCONATE LACTONIZING ENZYME. T. Kajander, L. Lehtio, S. Helin, and A. Goldman [1], D.M. Cohen and P.C. Kahn [2], U. Schell [3], [1]Centre for Biotechnology, University of Turku and Abo Akademi University, Turku, Finland, [2]Department of Biochemistry and Microbiology, University of Rutgers, New Brunswick, USA, [3] Institute for Microbiology, University of Stuttgart, Stuttgart, Germany

It is a well known fact that the hydrophobic effect is the main stabilising force in protein folding. On the other hand the per centage of charged accessible surface buried in proteins increases as the size of the protein increases. Therefore buried charge for enzymes may be a way to destabilise the structure as the size of the hydrophobic core increases. This can be necessary to i ntroduce strain or flexibility required for e.g. catalytic activity. Also, charged residues can have specific structural roles, sometimes even on the expense of stability, in any case providing a partial explanation for the marginal stability of proteins, regardless of their size [1]. We have further studied the effect of hydrophobic mutations on such buried charges in muconate lacto nizing enzyme (MLE) [2], which has a particularly hydrophilic hydrophobic core [2]. We have established unfolding conditions for MLE (an octamer of multidomain monomers of 40 kDa) with a single thermal transition in 0.4 M GndHCl and measured unfolding as a func tion of temperature by fluorescence emission at a maximum of 337 nm with a Tm of 50 C for the wild type. For one of the varia nts, D178N Tm=54 C. The structure of D178N variant at 2.5 A shows that the main cause for increase in Tm is the removal of charge, as the isosteric asparagine replaces D178 without any distortion of the protein.

P08.04.011 HARVESTING NATURES DIVERSITY TO IMPROVE PROTEIN STABILITY. A. Shaw, A.G. Day, C. Mitchinson, Bott R. Genencor International Inc 925 Page Mill Rd. Palo Alto CA94304 USA.

Currently, industrial scale starch liquefaction is constrained to operating at pH6.0 and above, with resulting economic disadvantages. More economically advantageous low pH liquefaction is prevented because the enzyme used in the process, Bacillus licheniformis a-amylase (BLA) becomes unstable at lower pH, at the high temperature used. The aim of this study was to engineer a BLA variant that can be used at low pH and high temperature. The results have led to the development of a very simple, yet rational method for identifying stabilizing variants, based on natures existing diversity. The implications of these results are that there is sufficient sequence diversity in nature to realize protein engineering goals. The key is to understand how to harness this diversity for success. As the biological information explosion continues, utilizing natures diversity will play a increasingly prominent role in development of rational protein engineering methods.

P08.04.012 STRUCTURE-BASED ASSIGNMENT OF BIOCHEMICAL FUNCTION OF A HYPOTHETICAL PROTEIN: A TEST CASE OF STRUCTURAL GENOMICS. Thomas I. Zarembinski[*‡], Li-Wei Hung[*‡], Hans-Joachim Mueller-Dieckmann[*‡], Kyeong-Kyu Kim[*‡], Hisao Yokota[*], Rosalind Kim[*], and Sung-Hou Kim[*‡]. [*]Physical Biosciences Division of Lawrence Berkeley National Laboratory, [‡]Department of Chemistry, University of California, Berkeley, CA 94720

As a test of structure-based functional assignment of proteins of unknown function, we report the crystal structure of one such protein, MJ0577, from a hyperthermophile, *Methanococcus jannaschii*, at 1.7-Å resolution. The structure contains a bound ATP, suggesting MJ0577 is either an ATPase or an ATP-mediated molecular switch which we confirm by biochemical experiments. Furthermore, the structure reveals different ATP binding motifs that are shared among many homologous hypothetical proteins in this family. This result indicates that structure-based assignment of molecular function is a viable approach for the large-scale biochemical assignment of proteins and for discovering new motifs, a basic premise of structural genomics.

P08.04.013 PROTEOMICS AND THE SHOTGUN APPROACH TO STRUCTURE. Thomas S. Peat, Janet Newman, Geoff Waldo & Thomas C. Terwilliger Los Alamos National Laboratory, NM, USA

Sequence information from the human genome, as well as other genomes, is entering public databases at an astonishing rate. The sequences of at least 20 microbes have been completed and the entire sequences of two eukaryotes are now known (S. cerevisiae and C. elegans). Many more microbial genomes are being sequenced and the entire human genome should be known within the next three years. This genetic information codes for a wide variety of proteins and RNA, many of which were previously unknown. This large number of novel molecules needs to be examined biochemically and structurally. The initial results of a Pilot Investigation into Genomic Structures (PIGS) is reported here. 42 open reading frames (ORFs) were chosen from the recently sequenced hyperthermophile Pyrobaculum aerophilum for PCR amplification from genomic DNA. 36 of these expressed protein when put into an expression vector and 20 of these were soluble at least to some level. Six of these proteins expressed well and were highly soluble. These six were purified and set up in crystallization screens and of these, two crystallized. Both structures are presented as well as the details of this pilot investigation.

P09.04.001 CRYSTALLIZATION OF HIV-1 PROTEASE IN THE COMPLEX WITH PEPTIDOMIMETIC INHIBITORS. H. Jerabkova, J. Hasek, Institute of Macromolecular Chemistry AS CR, Heyrovskeho nam. 2, 162 06 Praha 6, CR, J. Brynda, Institute of Molecular Genetics AS CR, Flemingovo nam. 2, 166 37 Praha 6, CR, M. Hradilek, Institute of Organic Chemistry and Biochemistry AS CR, Flemingovo nam. 2, 166 37 Praha 6, CR

Inhibitors of HIV-1 protease are promising therapeutic agents studied in the treatment of AIDS. Determining of precise interactions between inhibitors and protease by crystallographic techniques can be helpful in explaining the basis of effective inhibition and lead to design of new drugs [1]. Most tight-binding inhibitors of HIV-1 protease are believed to contain isosteric hydroxyl group that forms a hydrogen bond with the active-site aspartates. However the inhibitor without isosteric hydroxyl group showed in our tests stronger inhibition than most of the structures with hydroxyl group [2].

Complexes of HIV-1 protease with inhibitors of hydroxyethylamine type - Boc-Phe[$CH(OH)CH_2NH$]Phe-Gln-Phe-NH_2 (K_i = 14 nM) and ethylamine type Boc-Phe[CH_2CH_2NH]Phe-Glu-Phe-NH_2 (K_i = 0.05 nM) have been subjected to the crystallization screening. Ammonium sulphate, ammonium phosphate, PEG-4000 and NaCl were used as precipitants at pH 4-5. Best results were obtained by vapour diffusion technique at 6-8 °C.

P09.04.002 *IN-SITU* STUDY OF DEHYDRATION-INDUCED RELAXATION AND DISORDER IN PROTEIN CRYSTALS. I. Dobrianov, C. Kimmer, C. L. Caylor, S. G. Lemay, K. D. Finkelstein, and R. E. Thorne, Cornell University, Ithaca, NY 14850 USA.

Controlled crystal dehydration provides a simple model for the effects of post-growth crystal treatments such as heavy atom compound binding, ligand binding, and cryoprotectant soaks. These treatments all involve molecular diffusion through the crystal, can cause changes in lattice constant, molecular hydration and conformation, and these in turn can cause lattice strains, cracking, mosaic broadening and changes in diffraction resolution. Dehydration studies using lysozyme show that the unit cell shrinks and that the molecules shift, rotate, and undergo small conformational changes as water loss increases. Below 90% r.h., the diffraction resolution degrades dramatically.

We have used X-ray topographs, mosaic and θ-2θ scans, and diffraction patterns collected *in situ* during dehydration of tetragonal lysozyme crystals to study how lattice constants, lattice strains, defects, and diffraction resolution evolve in time. X-ray images reveal characteristic patterns of disorder that are suggestive of a crystal drying out. For dehydrations to 83-87% r.h., the image contrast completes its evolution in 2-3 hours, and lattice constants reach steady-state values in a comparable time. However, the time for degradation of the diffraction resolution varies from an hour to several days much longer than the time for equilibration of the crystal water content with the largest variations occurring for relative humidities above 86%. This suggests that lysozyme molecules can remain in an ordered metastable configuration for extended periods before undergoing the motions and conformation changes that degrade the diffraction resolution. Consequently, for more general post-growth treatments, the development of methods for maintaining the lattice in a metastable configuration may allow high-quality data to be obtained when a given treatment introduces substantial equilibrium disorder.

We have used X-ray topography and other diffraction measurements to characterize the response of tetragonal lysozyme crystals to dehydration. Topographs show characteristic patterns of disorder including cracks and dislocations that are suggestive of a crystal drying out.

P09.04.003 THE CRYSTALLIZATION AND CRYSTAL STRUCTURE OF A BOWMAN-BIRK INHIBITOR FROM VIGNA UNGUICULATA. K. N. Rao, C. G. Suresh [1], R. Lewis [2], [1] Division of Biochemical Sciences, National Chemical Laboratory, Pune-411008, India, [2] Department of Chemistry, University of York, York YO1 5DD, U.K.

The seeds of leguminous plants are a good source of protein inhibitors of proteases. The occurrence of several iso-inhibitors in these plants makes the purification and characterisation of a single inhibitor difficult. Bowman-Birk type inhibitors (BBI's) are low molecular weight proteins and the presence of several disulphide bridges in them imparts a compact structure to the protein. The Vigna unguiculata seeds contained many double-headed (trypsin / chymotrypsin) Bowman-Birk type iso-inhibitors. We have isolated and purified a single iso-inhibitor from these seeds.

The inhibitor crystals were obtained using hanging drop vapour diffusion method at pH 4.0 and 30% saturated ammonium sulphate from a 50 mg / ml protein solution. The crystals were in monoclinic space group P21 with cell dimensions a = 32.4, b = 61.8, c = 32.9 Angstroms, beta = 114.5 degrees. The X-ray data were collected under cryo (120 K) conditions. The crystals were small and diffracted to 2.5 Angstrom resolution only. The structure was solved using molecular replacement method with tracy bean BBI co-ordinates (PDB entry 1PI2) as model. The asymmetric unit was a dimer of closely interacting monomers. The Matthew's number calculated from MW 15,500 Da for the dimer was 1.95 Angstroms 3/D, and the corresponding solvent content was 37%.

P09.04.004 HOW DO MACROMOLECULAR IMPURITIES CREATE DISORDER IN PROTEIN CRYSTALS? C. L. Caylor, I. Dobrianov, S. G. Lemay, C. Kimmer, S. Kriminski, and R. E. Thorne, Laboratory of Atomic and Solid State Physics, Cornell University, Ithaca, NY 14853 USA; K.D. Finkelstein, Cornell High-Energy Synchrotron Source (CHESS), Ithaca, NY 14853 USA; W. Zipfel, Department of Applied and Engineering Physics, Cornell University, Ithaca, NY 14853 USA; B. R. Thomas and A. A. Chernov, Center for Microgravity and Materials Research, University of Alabama in Huntsville, Huntsville, AL 35899, USA.

At times responsible for dislocation and crack formation, generation of twins and polycrystalline and amorphous aggregates, and degradation of crystal mosaicity and diffraction resolution, macromolecular impurities present in growth solutions are among the most important factors affecting protein crystal growth and quality. The mechanisms by which macromolecular impurities degrade crystal diffraction properties have been investigated using X-ray topography, high-resolution diffraction line shape measurements, crystallographic data collection, chemical analysis, and two-photon excitation fluorescence microscopy. Hen egg-white lysozyme crystals grown from solutions containing either a structurally unrelated protein (ovotransferrin) or a related protein (turkey egg-white lysozyme) can exhibit significantly broadened mosaicity due to formation of cracks and dislocations but have overall B factors and diffraction resolutions comparable to those of crystals grown from uncontaminated lysozyme. Direct fluorescence imaging of the three-dimensional impurity distribution shows that impurities incorporate with different densities in sectors formed by growth on different crystal faces and that impurity densities in the crystal core and along boundaries between growth sectors can be much larger than in other parts of the crystal. These nonuniformities create stresses that drive formation of the defects responsible for the mosaic broadening. Our results provide a rationale for the use of seeding to obtain high-quality crystals from heavily contaminated solutions and have implications for the use of crystallisation for protein purification.

P09.04.005 PURIFICATION AND CRYSTALLISATION OF RECOMBINANT HAMSTER DIHYDROOROTASE. M. J. Maher, D. T. C. Huang. C. A. Collyer and R. I. Christopherson, Department of Biochemistry, University of Sydney, NSW 2006, Australia.

Infection with malarial parasites is one of the major infectious causes of mortality worldwide. The evolution of drug resistant organisms increasingly compromises our ability to treat this disease. Consequently, it is necessary to identify new exploitable therapeutic targets and discover potential inhibitors for these targets. Dihydroorotase catalyses the third reaction in the pathway for *de novo* biosynthesis of pyrimidine nucleotides, which leads to the synthesis of RNA and DNA. The malarial parasite *Plasmodium falciparum*, in contrast to humans, is unable to scavenge uridine as a precursor of pyrimidine nucleotides. Therefore blockage of its dihydroorotase activity is toxic and eventually fatal to the organism.

Hamster dihydroorotase has been purified from the soluble extract of *Escherichia coli* using ammonium sulfate fractionation, affinity and anion exchange chromatographies [1]. The final anion exchange step is crucial to obtaining highly pure, crystallisable protein. The protein as isolated is a dimer, with one Zn atom per subunit and a specific activity of 2.5-3.0 units/mg. After testing a wide range of crystallisation conditions, we have obtained crystals of dihydroorotase under three different conditions: sodium formate as precipitant at pH 6.0-6.6 (rod-shaped crystals of maximum dimensions 0.2 x 0.02 x 0.02 mm); sodium formate as precipitant at pH 7.5 (lens-shaped, plate-like crystals of maximum dimensions 0.3 x 0.1 x 0.02 mm, weak diffraction to an approximate resolution of 8 Å has been recorded) and ammonium sulfate as precipitant, pH 6.5 (bipyramidal crystals of 0.05 mm in their maximum dimension).

P09.04.006 CRYSTALLIZATION AND CRYSTALLOGRAPHIC STUDIES OF PHOSPHOENOLPYRUVATE CARBOXYLASE FROM MAIZE. H. Matsumura[1], M. Terada[1], S. Shirakata[1], T. Inoue[1], Y. Kai[1], T. Yoshinaga[2], Y. Ueno[3] and K. Izui[3], [1]Department of Materials Chemistry, Graduate School of Engineering, Osaka University, Suita, Osaka, 565-0871, [2]Department of Public Health, Graduate School of Medicine, and [3]Division of Applied Biosciences, Graduate School of Agriculture, Kyoto University, Sakyo-ku, Kyoto, 606-8501, Japan.

Phosphoenolpyruvate carboxylase (EC 4.1.1.31) is a key enzyme in the fixation of atmospheric CO_2 in C_4 and crassulacean acid metabolism (CAM) plants. PEP carboxylase catalyses the irreversible carboxylation of PEP to form oxaloacetate and inorganic phosphate, the first committed step in the fixation of external CO_2 in these plants. The enzyme from maize is activated by glucose 6-phosphate and glycine, while it is inhibited by malate. Its sensitivity to malate is significantly reduced by phosphorylation at Ser-15 in the light. PEP carboxylase from maize is a homotetrameric enzyme with a molecular mass of approximately 440 kDa. It is important to determine the three-dimensinal structure of PEP carboxyalse from maize and to

elucidate the light-induced regulation of PEP carboxylase in plants.

PEP carboxylase was purified from the leaves of maize plants in the light period, and crystallized by the hanging-drop vapor diffusion method at 293 K. The typical size of these crystals was 0.5 x 0.3 x 0.05 mm. The X-ray diffraction data for native crystals were collected at the synchrotron radiation source of the Photon Factory (Tsukuba, Japan). The diffraction pattern of the crystal extends to 3.0Å resolution. The PEP carboxylase crystals belong to an orthogonal space group $C222_1$ with lattice constants of a = 160.2, b = 175.6, and c = 255.5 Å. Presently we are trying to solve the structure by the molecular replacement method, in parallel with the isomorphous replacement technique.

P09.04.007 THE IMPORTANCE OF THE ISO-ELECTRIC POINT IN PROTEIN CRYSTALLIZATION. Abel Moreno [1], Víctor Martín Bolaños-García, Jaime Mas-Oliva [2], [1] Departamento de Bioquímica, Instituto de Química, UNAM. México D.F. CP04510 Deleg. Coyoacan. MEXICO. [2] Departamento de Bioquímica, Instituto de Fisiología Celular, UNAM. México D.F. CP04510 Deleg. Coyoacan. MEXICO.

It is well known that the availability of crystals has been the bottle neck for many years. This is because little has been explored on the physical and chemical properties of the protein solutions to study in detail the crystallization phenomena [1, 2]. In this work, the influence upon aggregation behavior of the temperature as well as the pH over model proteins, such as hen egg white lysozyme and thaumatin I from Taumatococcus daniellii, is reported. Additionally, it is shown a new device, based on the gel acupuncture implementation [3], used for studying the influence of the isoelectric point upon protein crystallization. It is also presented and discussed how by using this new device it is possible to explain the crystal growth phenomena and the aggregation behavior throughout the crystallization experiments. A photographic recording of the crystal growth of lysozyme and thaumatin was obtained as a function of the pH as well as for the temperature.

P09.04.008 THE USE OF MERGED PROTEIN CRYSTALLIZATION TECHNIQUES FOR THE STUDY OF PROTEIN NUCLEATION PHENOMENA. Víctor Martín Bolaños-García, Jaime Mas-Oliva [1], Abel Moreno [2], [1] Departamento de Bioquímica, Instituto de Fisiología Celular, UNAM. México D.F. CP04510 Deleg. Coyoacan. MEXICO, [2] Departamento de Bioquímica, Instituto de Química, UNAM. México D.F. CP04510 Deleg. Coyoacan. MEXICO.

There is a growing interest to develop new practical techniques for increasing the quality of protein crystals as well as crystal growth techniques for X-ray investigations. If well many advances have been obtained on the crystallization of proteins, most of the time it is necessary to growth the crystal up for 3D structural studies. The aim of this work is to solve the problem of growing crystals up to maximum size with high optical and structural qualities for X-ray analysis, merging several crystal growth techniques. In order to have comparable results, three model proteins have been evaluated focused on their crystal growth: lysozyme, thaumatin and concanavalin A. We have taken into account the new trends in crystal growth and it was developed the first set-up of a new crystal growth design for protein crystallization. This new design was based on the gel acupuncture technique [1] and the crystallization of proteins using oils as it has been published by Naomi Chayen et al., [2]. Our proposal combines the transport properties using gels as a dialysis membrane and the oil as a new hypothetical membrane. Finally, we show how using these (oil/gel) barriers it is possible to control the nucleation process and the rate of reaching supersaturation.

P09.04.009 ROLE OF PURITY OF RESTRICTION ENDONUCLEASE *Eco*RII IN THE CRYSTALLIZATION PROCESS OF THIS ENZYME. Elisaveta A. Karpova, Biophysics ES 76, NASA/MSFC, Huntsville, USA 35812

The effect of protein purity on the crystallization process and resulting quality of crystals grown are broadly discussed. We have obtained crystals of restriction endonuclease *Eco*RII (*Eco*RII), space group I23 and cell parameters a = b = c = 160 Å, $\alpha = \beta = \gamma = 90^o$, and have studied the influence of the purity of this enzyme on the crystal growth process. *Eco*RII endonuclese belongs to type II restriction-modification enzymes (subclass IIe). *Eco*RII catalyzes the specific cleavage of double strand DNA at specific site 5'-↓CCA/TGG-3' (the cleavage position is indicated by the arrow (↓)).

This enzyme was purified by 4 and 5 steps purification procedures using ion-exchange and affinity chromatography. Two samples with different purity were characterized by SDS-gel electrophoresis and by specific activity test. We will present the crystallization data of these two different samples and influence of their purity on the crystallization process and quality of grown crystals.

This work is supported by National Research Council Research Associated Programs at MSFC, USA

P09.04.010 PURIFICATION AND CRYSTALLI-ZATION OF MYELIN BASIC PROTEIN. Andy Freer, Tanweer Ahmed, Ruijun Pan, Department of Chemistry, University of Glasgow, Glasgow G12 8QQ & Ian Griffiths, Veterinary School, Garscube Estate, University of Glasgow, Glasgow G61 1QK, UK.

Compact myelin, the insulating material of axons, contains a high proportion of lipid and several proteins which are highly enriched in, or specific to myelin. The highly hydrophobic transmembrane proteolipd protein, PLP and the extrinsic, hydrophilic myelin basic protein, MBP are the major myelin proteins of the central nervous system (CNS) accounting for 50% and 30% respectively of total protein. Myelin, is essential for the salutatory conduction of impulses and its loss or malformation leads to devastating consequences as demonstrated in multiple sclerosis (MS), acute disseminating encephalomyelitis and myelinosis which are primarily associated with MBP and several fatal genetic disorders associated with mutations in PLP. Presently, there is little structural information as to the role of these membrane proteins in myelination and hence our understanding of the architecture of the compact myelin sheath and the molecular pathology of diseased myelin is limited.

In this paper we describe a novel procedure for the isolation and purification of MBP under non-denaturing conditions which preserves secondary structure. Essentially, we treat MBP as a true membrane protein and extract using the mild detergent LDAO. The MBP isoforms were separated by conventional cation exchange chromatography using CM52. By employing these milder conditions purification is effected in the absence of lipid. This lipid free protein (LF-MBP) is different from that extracted by conventional acid/methanol routes, but may be similar to the lipid bound protein (LB-MBP) as extracted by

Riccio *et al*. The striking similarity here is that both are CD active, indicating secondary structure, whereas classical methods denature the protein. We also clearly identified the presence of a dimer and monomer form of MBP (applicable to several of the isoforms) and showed that only the dimer was CD active, with secondary structure which approximated to that predicted from the amino acid sequence.

Having obtained the major isoform of MBP as a pure dimer, crystallization trials were set up using conventional screening procedures. Crystals were obtained from several of the screening conditions indicating PEG as the precipitant. We have collected data on crystals from three of these conditions to a resolution of 2.8 Å with our in house Nonius DIP system. From the best condition we have 98% completion with unit cell dimension: a = 36.037 , b = 42.791, c = 96.009 Å, β = 95.02 ° in the space group $P2_1$ which gives (from a Matthews value of 2.1) one dimer per asymmetric unit. A partial platinum derivative has just been collected.

Riccio, P., Rosenbusch, J.P. & Qualgliariello, E. (1984) FEBS Lett. 177, 236-244.

P09.04.011 INTERNAL CARRIER PROTEINS FOR THE IMPROVEMENT OF THE CRYSTALLIZATION POTENTIAL OF MEMBRANE PROTEINS. C.K. Engel, L. Chen [1], H.R. Kaback [2], G.G. Privé [1], [1] Ontario Cancer Institute, 610 University Av., Toronto, CA, [2] HHMI, University of California Los Angeles, USA

Two of the main problems in the crystallization of membrane proteins are the difficulty to produce large amounts of stable protein, and the small polar surface area for crystal contact formations. We try to overcome these problems simultaneously by creating internal fusion proteins, where soluble carrier proteins are fused into loop regions of the membrane protein. The carrier protein increases the polar surface area of the fusion protein and therefore the stability in solution and the area available for crystal contact formation. In addition, carriers can be used to introduce convenient spectral or enzymatic properties, making the fusion protein easier to handle than the native molecule [ref. 1]. As model system we use the lactose (lac) permease, a secondary transporter from Escherichia coli. It has been shown [ref. 2], that cytochrome b562 (cyt. b562) can be fused into the central internal loop at the intracellular side of lac permease. The construct was successfully expressed and purified. It showed similar lactose transport activity as the wild type lac permease and essentially identical absorption spectra as native cyt. b562. Absorption in the visible range by the cyt. b562 carrier gives the fusion protein a red color ('red permease') and makes it easy to monitor expression, purification and concentration of the construct. The fusion construct can be expressed in high quantities and purified to homogeneity. In respect to crystallization, larger carrier proteins with a larger polar surface area are expected to have improved properties. We are therefore investigating other soluble proteins as carriers. We have introduced, for example, the 20 kD FAD-dependend flavodoxin from Escherichia coli into the central loop of lac permease. Although this carrier is considerably larger than cyt. b562, both fusion constructs show the same activity in respect to lactose transport. We are currently optimizing the expression and purification procedure for this construct. All constructs will be tested for their crystallization potential. Our ultimate goal is the crystallization and successful structure determination of lac permease.

P09.04.012 CRYSTALLISATION OF TRANSTHYRETIN LOCKED IN AMYLOID FOLD. A. Hörnberg[1], A. Olofsson[2], E. Lundgren[2], and E. Sauer-Eriksson[1]. ([1]Umeå Center for Molecular Pathogenesis and [2]Department of Cell and Molecular Biology, Umeå University, S-901 87 Umeå, Sweden.)

Transthyretin (TTR) is a human plasma protein composed of four identical subunits (127 residues each). The protein is predominantly synthesised in the liver with the main function in transporting the thyroid hormone, but it also plays a major role in the transport of the hydrophobic vitamin A. TTR is normally a stable and soluble protein, however under certain conditions the protein can alter its conformation and form insoluble amyloid fibers. The accumulation of TTR fibers cause two different human diseases, senile systemic amyloidosis (SSA) and familial amyloidosis with polyneuropathy (FAP I).

In order to understand the nature of the structural changes required for generation of amyloid new TTR-mutants with high potential to form amyloid have been constructed [1]. Against these mutants monoclonal antibodies have been generated [2]. These antibodies also display activity against amyloid fibres, but not to wildtype TTR or mutants exhibiting the wildtype fold. We have initiated a crystallographic project with the aim to determine the structure of such a mutant/antibody complex. Crystallisation trials are in progress.

P09.04.013 TWO CRYSTAL FORMS OF 20S PROTEASOME FROM BOVINE LIVER. M.Unno[#1], Y.Tomisugi[#2], T.Mizushima[#1], Y.Morimoto[#2], N.Yasuoka[#2], K.Tanaka[#3] and T.Tsukihara[#1], #1. Institute for Protein Research, Osaka University, 3-2 Yamada-oka, Suita, Osaka 565-0871, JAPAN, #2.Department of Life Science, Himeji Institute of Technology, Kamigohri Akoh, Hyogo 678-1297, JAPAN, #3. The Tokyo Metropolitan Institute of Medical Science, 3-18-22 Honkomagome, Bunkyo-ku, Tokyo 113-0021, JAPAN

Proteasomes are large, non-lysosomal, multicatalytic proteinase. It is responsible for the degradation of intracellular proteins, a process important for regulation of metabolism and cell division and, in higher animals, for immunological responses. The crystal structures of 20S proteasomes from the archaebacterium and from the yeast have been reported by R.Huber *et al*. However, that of mammalian has been not reported. So we are trying to determine the 3D structure of 20S proteasome from bovine liver.

We prepared and crystallized 20S proteasome from bovine liver. Some crystals diffracted x-rays up to 2.5A when using synchrotron radiation. These crystals belonged to $P2_12_12_1$ with cell dimensions a=122Å, b=193Å, c=319Å. However, the crystals were quickly deteriorated and couldn't collect the full data set from one crystal. So We have purified and crystallized repeatedly. Crystals were obtained in almost same conditions, but the concentration of buffer or salt was a little different. When we collected x-ray diffraction data of another crystal, we found the second crystal form. The second type of crystals belong to $P2_12_12_1$ with cell dimensions a=203Å b=319Å c=360Å.

We determined the preliminary phase of the first crystal by molecular replacement method. And we calculated self rotation function of the second crystal and found non-crystallographic 3-fold and 2-fold axes.

P09.04.014 CHARACTERIZATION AND CRYSTALLIZATION OF A NOVEL *SARCOCYSTIS MURIS* LECTIN. J. J. Müller[1], E.-Ch. Müller[2], A. Feske[1], H. Klein[3], Th. Montag[3], U. Heinemann[1] and A. Otto[2], [1]Forschungsgruppe Kristallographie, Max-Delbrück-Centrum für Molekulare Medizin, Robert-Rössle-Str. 10, D-13092 Berlin, Germany, [2]Forschungsgruppe Proteinchemie, Max-Delbrück-Centrum für Molekulare Medizin, Robert-Rössle-Str. 10, D-13092 Berlin, Germany, [3]Paul-Ehrlich-Institut, Federal Agency for Sera and Vaccines, FG Parasitologie/ Diagnostika, Paul-Ehrlich-Straße 51-59, D-63225 Langen, Germany.

A novel *Sarcocystis muris* major microneme antigen from cyst merozoites has been detected and analysed by Edman degradation and mass spectrometry whereby it was possible to find a new gene. This protein plays a role during host cell recognition by invading parasites. The protein consists of 138 amino acids with 72.5 % and 65.2% identity with the GEN2 and GEN4 products of the *Sarcocystis muris* genome establishing a new family. Significant homology exists with *Toxoplasma gondii* expressed sequence tags. All of the twelve cysteinyl residues build up disulphide bridges, two of those are attributed by mass spectrometry to motifs as found in diverse parasitic proteins, growth factors, and the apple domains of kallikrein and blood coaggulation factor XI [1]. Crystals of *Sarcocystis muris* lectin have been grown by vapor diffusion. The crystals belong to the primitive orthorhombic space group $P2_12_12_1$ with cell parameters A=53.57 Å, B=128.76 Å, C=158.18 Å. There are four molecules in the asymmetric unit. The crystals diffract to 2.1 Å resolution at 100°K at the EMBL BW7A beamline at the DORIS storage ring , DESY, Hamburg.

P09.04.015 EFFECTS OF AN EXTERNAL ELECTRIC FIELD ON THE PROTEINS CRYSTALLIZATON C. Didierjean, M. Taleb, C. Jelsch, J. P. Mangeot, A. Aubry, Groupe Biocristallographie, Laboratoire de Cristallographie et Modélisation des Matériaux Minéraux et Biologiques UPRESA CNRS 7036, B. P. 239, 54506 Vandoeuvre-lès-Nancy, France, B. Capelle, Laboratoire de Minéralogie et Cristallographie UMR CNRS 7590, case 115, 4 place Jussieu, 75252 Paris, France.

Protein molecules contain different ionic and polar groups. As a result, they inherently have a quite significant charge depending on the pH of the solution. The environment of the molecules and of their aggregates in the crystallization medium can be changed when applying an external electric field. The interaction of charged molecules with an external electric field might alter their distribution inside the solution and lead to local nucleation. From these considerations, it is possible to imagine that the external electric field can influence the crystallization of proteins and possibly promote the formation of crystals with good quality and size. The purpose of the present poster is to show the effects of an external electric field on the crystallization of biological macromolecules.

Very pure lysozyme protein at pH 4.5, with sodium chloride as crystallizing agent, has been crystallized. Two experimental devices have been developed. The first one has allowed observing a slight effect of the electric field on the crystallization by reducing the mosaic spread of the crystals. In order to increase the strength of the electric field in the crystallization solution, a second device has been developed in which many dielectric media were eliminated. An undeniable effect of the electric field has been observed in this case especially on the number and size of crystals. The electric field affects strongly the nucleation rate of lysozyme. In addition the behavior of the protein in solution under an electric field has been studied. Results concerning the concentration variation of the lysozyme into the solution and solubility diagrams will be presented.

P09.04.016 CRYSTALLIZATION OF A PUTATIVE TRANSCRIPTION FACTOR, ASNC AND 3-METHYL ADENINE GLYCOSYLASE FROM A HYPERTHERMOPHILIC ARCHAEBACTERIUM, *PYROCOCCUS* sp. OT3. Norio Kudo[1,2], Mark, D. Allen [2], Hideaki Koike[2], and Masashi Suzuki[1,2] ([1] Graduate School of Human and Environmental Sciences, University of Tokyo, [2] AIST-NIBHT, CREST Centre of Structural Biology)

We report crystallization of 3-methyl adenine glycosylase and a putative transcription factor, AsnC, from a hyperthermophilic archaebacterium, *Pyrococcus* sp. OT3.

The proteins were expressed by *E. coli* systems and purified. Crystals were grown by the sitting drop vapour diffusion method at 5°C, using PEG 6000 and LiCl as precipitant for the glycosylase and AsnC, respectively. The crystal of the glycosylase was shown to diffract X-ray upto 3.0Å. The space group was identified to be rhombic, R32. Three independent molecules were identified positioning in the asymmetric unit of 168.0x 168.0x 117.0Å. The crystal of AsnC was shown to diffract X-ray upto 2.3Å. The space group was identified to the hexagonal. Four independent molecules were identified positioning in the asymmetric unit of 97.0x 97.0x 98.3Å.

Archaebacteria are different from eukaryotes or eubacteria, and constitute the life's third domain. While analyzing archaebacterial genomic DNA sequences we noticed that the transcription and replication systems were chimera of eukaryotic and eubacterial ones. The AsnC protein and the 3-methyl adenine glycosylase are eubacterial representatives involve in the archaebacterial systems, and thus determination of their 3D structures is expected to contribute to the understanding of the origin and evolution of living organisms.

P09.04.017 CRYSTAL STRUCTURE OF HEN EGG-WHITE LYSOZYME WITHIN HIGH MAGNETIC-FIELD ENVIRONMENT T.Sato, Department of Life Science, Faculty of Bioscience and Biotechnology, Tokyo Institute of Technology, Yokohama, Japan, and G.Sazaki, Institute for Materials research, Tohoku University, Sendai, Japan and Y.Katsuya, Hyogo Prefecture Industrial Technology Center, Kobe, Japan and Y.Matsuura, Institute for Protein research, Osaka University, Suita, Japan

Crystals of tetragonal hen egg-white lysozyme were grown with the high magnetic apparatus of High Field Laboratory for Superconducting Materials, and without a magnetic field, respectively. Both crystals were grown in 2.5% NaCl as a crystallizing agent at pH 4.5. The X-ray diffraction patterns of the best diffracting crystals were recorded using R-AxisIIc and an imaging plate system. The crystals grown with and without a magnetic field showed the similar maximum resolution upto 2Å. In the presence of a magnetic field, the number of formed crystals decreased because of the low nucleation rate. The *a* and *b* axes of the unit cell expanded by 0.2%, or *c* axis also increased by 0.1%. In general, the crystals of a variety of diamagnetic proteins, e.g. lysozyme, may be perfectly aligned by an intense static external magnetic field due to the slight anisotropy in the magnetic susceptibility of the protein caused by the three structural elements ; alpha-helix, beta-sheet and the aromatic rings of amino acid residues. Structure refinement of the crystals have been carried out with the program X-PLOR. The two structures are nearly identical with the root-mean-square deviation on all protein atoms. The changes in the ordered water molecules and the expansibility of all of the solvent in the crystal will be reported here. Two ions consist of one chloride ion and one sodium ion at the interface between adjacent lysozyme molecules. These ions may stabilize a

crystal packing. We may have obtained highly ordered arrays of diamagnetic protein by the effect of a magnetic field, which permitted us to gain larger crystals. When lysozyme is placed in a direct current magnetic field of 10 Tesla strength the protein molecules become highly ordered, aligning their long axis perpendicular to the field direction. Clearly then, the protein crystals can be aligned by the field and must thus have their crystal susceptibility along the field direction, corresponding to crystallographic *c* axis. It was then evident that we can suppress formation of the crystallising nuclei owing to increase solubility of the protein with this magnetic arrangement. It is sugested that the application of a magnetic field may be allowed to improve protein crystal growth from microcrystals.

P09.04.018 A RATIONAL APPROACH TO GROW AND TREAT CRYSTALS OF HCMV PROTEASE AND ITS INHIBITOR COMPLEX. Chungeng Qian [1], Lisette Lagacé [2], Marie-Josée Massariol [2], Catherine Chabot [2], Christiane Yoakim [2], Robert Déziel [2], Liang Tong [1]. [1]Boehringer Ingelheim Pharmaceuticals, Inc.,900 Ridgebury Road/P. O. Box 368, Ridgefield, CT 06877, U.S.A. [2]Boehringer Ingelheim(Canada) Ltd., Bio-Méga Research Division, 2100 rue Cunard, Laval, Québec, Canada H7S 2G5.

Protein crystallization is generally regarded as a field of art rather science. Here we demonstrate that one could do better if exploring scientific approach during crystallization trials, the way in which we have crystallized both hCMV protease and its inhibitor complex. For free enzyme crystals, we put tremendous effort to improve the diffraction limit by optimizing crystallization conditions, raising precipitant concentration in reservoir and soaking crystals in artificial mother liquors containing six components. Crystals diffracting to 2.0Å resolution were finally obtained, leading to the elucidation of the three dimensional structure of the enzyme using MAD method. For inhibitor complex crystals, initial attempts with co-crystallization and soaking experiments at pH 6.0 did not produce conclusive results. We therefore choose to co-crystallize the complex at pH 8.0, optimal for the enzyme and the inhibitor activity. Using 20 to 50 mM spermine in the crystallization buffer, crystals of two peptidomimetic inhibitor complexes were obtained at pH 7.5 and 8.0 respectively. Spermine was required for the inhibitor complexes to be crystallized at pH 8.0, possibly neutralizing net negative charges of hCMV protease due to its acidic pI 5.5. A 2.7Å data set was collected from one of the inhibitor complex and the structure determined using molecular replacement method.

P09.04.020 INVESTIGATION OF RAT BRAIN L-3-HYDROXYACYL-CoA DEHYDROGENASE AND IT'S ROLE IN ALZHEIMER'S DISEASE. Ailsa Powell[*], Frank Gunn-Moore[+], Leo Brady[*], [*]University of Bristol, UK, [+]University of Edinburgh, UK.

The human brain L-3-hydroxyacyl-CoA dehydrogenase (LHCDH) has been found to have an identical primary sequence to endoplasmic reticulum amyloid β-peptide binding protein (ERAB)[1].

LHCDH is an intracellular enzyme that catalyses the following reaction, which is the third step of the fatty acid β-oxidation pathway: L-3-hydroxyacyl-CoA + $NAD^+ \leftrightarrow$ NADH + H^+.

In Alzheimer's disease, amyloid β-peptide binds ERAB and causes it to redistribute to the plasma membrane. The neuronal dysfunction and death found in Alzheimer's disease has been linked to the presence of extracellular amyloid β-peptide in the brain. ERAB is overexpressed in Alzheimer's disease, but by blocking ERAB it is possible to prevent the toxic effect of amyloid β[2].

The rat brain ERAB gene has been cloned into a pET-15b vector and has been expressed as a his-tagged protein. By crystallising and solving the structure of rat brain LHCDH, it may be possible to gain a better understanding of amyloid β toxicity in Alzheimer's disease. It is also hoped to identify inhibitors of this enzyme and see if they affect the binding of amyloid β-peptide.

P09.04.021 THE CRYSTAL STRUCTURE OF SUPERANTIGEN STREPTOCOCCAL PYROGENIC EXOTOXIN A1 WITH ZINC AT 2.8 Å RESOLUTION. M.D. Baker, A.C. Papageorgiou and K.R. Acharya, Department of Biology and Biochemistry, University of Bath, Claverton Down, Bath, BA2 7AY, UK, and C.M. Collins, Department of Microbiology and Immunology, University of Miami, FL 33101, USA.

Superantigens are toxins produced by several strains of *Staphylococcus aureus* and *Streptococcus pyogenes* with the unique ability to induce profound T-cell proliferation by cross-linking MHC class II molecules with T-cell receptors. These toxins act at nanomolar concentrations and unlike conventional antigen are not processed internally by the antigen presenting cells. Each superantigen activates a subset of the total T-cell repertoire bearing specific Vβ chains. Thus, superantigens are able to stimulate a much larger proportion of the T-cells than conventional peptide antigens. Crystallographic and biochemical [1] studies have suggested that superantigens have evolved a number of different ways to interact with MHC class II molecules and T-cell receptors despite their common overall architecture [3].

Streptococcal pyrogenic exotoxin A1 (SpeA1) is produced by *Streptococcus pyogenes* and has been associated with severe infections such as scarlet fever and Streptococcal Toxic Shock Syndrome (STSS) [2]. The crystal structure of SpeA1 has been determined at 2.6 Å resolution [3] and is similar to that of other superantigens , having the greatest similarity with staphylococcal enterotoxin C. A putative zinc binding site was identified, although no zinc ion was found to be present. Direct evidence for the binding of zinc to SpeA1 was obtained by soaking SpeA1 crystals in 2.5 mM zinc solution. Data to 2.8 Å resolution was collected at 100°K. The implications of zinc binding to SpeA1 for MHC class II recognition will be discussed.

P09.04.022 STRUCTURAL STUDIES ON THE TOXIC EFFECTS OF ORGANOCHLORINE PESTICIDES. M. Suwalsky and F. Villena, University of Concepcion, Casilla 160-C, Concepcion, Chile, and C.P. Sotomayor, Catholic University of Valparaiso, Valparaiso, Chile.

Organochlorine pesticides are ubiquitous in the environment because of their widespread use and persistence in soil. In general, the molecular mechanisms of pesticide toxicity are poorly understood. However, the lipophilicity of most compounds makes lipid-rich membranes a plausible target of their interaction with living organisms. Thus, alterations in the organization of their lipid bilayers are likely to constitute a mechanism for modulation of membrane protein functions. In the course of in vitro system search for the toxicity screening of chemicals, different cellular models have been applied to examine the adverse

effects of pesticides. We will describe the interaction of several organochlorine pesticides with cell membranes of human erythrocytes and molecular models. The latter consisted of bilayers built-up of dimyristoylphospatidylcholine (DMPC) and dimyristoyl-phosphatidylethanolamine (DMPE), representative of phospholipid classes located in the outer and inner monolayers of the human erythrocyte membrane, respectively. Considering the lipophilic nature of the pesticides and the amphiphilic character of phospholipids, their interactions were assayed in hydrophobic and aqueous media in a wide range of concentrations. The capacity of the pesticides to perturb the bilayer structure of DMPC and DMPE was determined by X-ray diffraction. Human erythrocytes incubated with the same compounds were observed by scanning electron microscopy to detect shape changes induced by the pesticides. Additional techniques such as fluorescence spectroscopy on large unilamellar vesicles and electrophysiological measurements of frog nerve-skin preparations incubated with the pesticides were also used. The experimental results allowed to conclude that organochlorine pesticides alter the molecular structure of lipid bilayers thereby modifying biophysical and physiological properties of cell membranes.

P09.04.023 3D STRUCTURES OF DROSOPHILA ACETYLCHOLINESTERASE: IMPLICATIONS FOR INSECTICIDE DESIGN. M. Harel, G. Kryger, J.L. Sussman [1], I. Silman [2], T.L. Rosenberry, W.D. Mallender [3], T. Lewis, R.J. Fletcher [4], M. Guss [5], [1] Department of Structural Biology, Weizmann Institute of Science, Rehovot 76100, Israel, [2] Department of Neurobiology, Weizmann Institute of Science, Rehovot 76100, Israel, [3] Pharmacology Department, Mayo Clinic, Jacksonville, FL 32224, USA, [4] Zeneca Agrochemicals, Jealott's Hill Station, Bracknell, Berkshire, UK, [5] Department of Biochemistry, University of Sydney, Sydney, NSW 2006, Australia

The 3D structures of Drosophila melanogaster acetylcholinesterase (DmAChE), and of its complex with an iodine-containing putative insecticide, were solved by a combination of SIR and molecular replacement, starting from the 2.7 A structure of Torpedo californica AChE (TcAChE), with which it has 36% sequence identity. The SIR phases were obtained by freeze-trapping of xenon atoms. The structures were refined to R=26.1% (R-free=30.5%) for the native structure, and R=23.0% (R-free=26.8%) for the complex. The structure of DmAChE shows the same overall fold and deep and narrow active-site gorge as TcAChE, human and mouse AChEs. It displays a Ca rms deviation of 0.78 A, using the 342 best fitting residues out of 586. However, there are large deviations (up to 8 A) in the positions of some loops, and the C-terminal helix is shifted by 3 A relative to TcAChE. The substitutions in 10 (out of 30) sidechains facing into the active- site gorge in DmAChE, relative to TcAChE, cluster mostly near the top of the gorge, near the peripheral binding site. Upon binding of the inhibitor, which resembles the anti-Alzheimer drug, tacrine, the aromatic rings of both the flexible mid-gorge residue, Y370(F330) [parentheses indicate TcAChe numbering], and of the choline-binding residue, W83(W84), change their conformation so as to stack against two aromatic groups of the inhibitor. The marked structural differences between the active-site gorges of the insect and vertebrate AChEs reveal several features which might provide the basis for more selective insecticides. The structure of DmAChE shows the same overall fold and deep and narrow active-site gorge as TcAChE, human and mouse AChEs.

P09.04.024 STRUCTURE OF HUMAN TRANSTHYRETIN COMPLEXED WITH ENVIRONMENTAL POLLUTANTS: A NEW MODE OF BINDING. Minakshi Ghosh, Atlanta Cook and Louise Johnson, Laboratory of Molecular Biophysics, University of Oxford, Rex Richards Building, South Parks Road, Oxford OX1 3QU, United Kingdom.

Transthyretin (TTR) is one of three serum proteins responsible for the transport of the hormone thyroxine. It has been found in recent years that some polyhalogenated aromatic hydrocarbons present in the environment interact with transthyretin in competition with thyroxine, its natural ligand. Evidences suggest that these compounds have a potentially adverse effect on the endocrine system of laboratory animals and may therefore harm both humans and wildlife (1). Pentabromophenol, which is used as a fire retardant, and 2,4,6-tribromophenol are two such compounds. They have shown high affinity for TTR. Pentabromophenol, in particular has a relative potency ~ 15 times that of thyroxine in vitro experiments.

Our current work has revealed some unusual and interesting features in the binding of bromophenol ligands with TTR. The crystal structures of human serum TTR, complexed with Pentabromophenol and 2,4,6-tribromophenol, have been solved and refined for 20-1.8Å resolution data.

Firstly, the ligands bind exclusively in the so-called “reverse mode”, with the phenolic group pointing towards the mouth of the binding cavity. This is in contrast with most other TTR-ligand structures where the phenolic group points towards the centre of the binding cavity. Secondly, for pentabromophenol, it is observed that the bindings of the ligand are different at two binding sites of the protein, in spite of the fact these sites are related by a non-crystallographic symmtery. This agrees with chemical data showing that there is a 100 fold difference in the binding affinities for the first and second thyroxine. In all the structural studies done prior to this current work, the ligands and the surrounding residues of the protein have shown to have identical conformations at the two binding sites.

P09.04.025 LOW RESOLUTION PROJECTION MAPS OF SCRAPIE PRION PROTEIN CRYSTALS FROM REVERSE MICELLAR SOLUTIONS. Holger Wille [1], Vincent Guenebaut, Robert M. Stroud, David A. Agard [2], Stanley B. Prusiner [1,2] [1] Institute for Neurodegenerative Diseases, Department of Neurology, University of California, San Francisco, CA 94143-0815, U.S.A. [2] Department of Biochemistry and Biophysics, University of California, San Francisco, CA 94143, U.S.A.

The N-terminally truncated scrapie isoform of the prion protein (PrP 27-30) is highly insoluble. Solubilization into monomers and dimers was only achieved through the use of reverse micellar systems. Three separate combinations of organic solvents and detergents were particularly successful in solubilizing PrP 27-30 (Wille and Prusiner, 1999, Biophys. J., in press). Divalent uranyl ions induced the solubilized prion protein to form small two- and three-dimensional crystals. Other multivalent metal ions did not induce PrP 27-30 to form crystals. Different reverse micellar solutions resulted in distinct crystalline lattices as judged by electron microscopy and electron diffraction. Image processing allowed us to analyze conventional electron micrographs to see if these crystals would give ultrastructural information on the scrapie isoform of the prion protein. We used correlation mapping and averaging on the crystal lattices to improve the signal to noise ratio. The limit of resolution in the power spectra was at ~2.5 nm with occasional spots out to ~1.2 nm. The latter images showed some intramolecular details that

could be interpreted as secondary structure elements. Other crystals appeared to contain prion protein dimers, and showed two separate uranyl-complexing densities per protein molecule, allowing speculations on the sites of glycosylation. The limitation to low resolution data stems from the type of instrument used and the practice of high dose imaging. Future efforts will focus on gathering high resolution data by use of low dose cryo-electron microscopy and attempt to improve the crystalline order.

P09.04.026 TETANUS TOXIN GANGLIOSIDE BINDING DOMAIN, 1.57Å NATIVE AND DERIVATIVE STRUCTURES. Mark Knapp, Brent Segelke, Bernhard Rupp. Macromolecular Crystallography Group, Lawrence Livermore National Laboratory, 7000 East Avenue, Mail Stop L-452, Livermore, CA 94550 USA.

The disease known as Tetanus is caused by a neurotoxin produced by the anaerobic bacterium *Clostridium Tenati.* It acts upon the presynaptic membranes of both central and peripheral nervous systems; its effect is to block the release of neurotransmitters causing paralysis. Tetanus toxin is a 150kDa protein made up of two major parts: a 50-kDa light chain and 100-kDa heavy chain. The light chain is the enzymatic portion of the protein responsible for its toxicity. The heavy chain is made up of a translocation domain and a 51-kDa component (the C Fragment) which binds to the gangliosides of the neuron cell membrane and determines neuron specificity.

The crystal structure of the C Fragment has been determined to 1.57Å resolution. Both native protein and heavy atom derivative structures are reported. Data for the native protein and two heavy atom derivatives (Hg, Au) were collected in-house to 2.5Å resolution. MIR phases were used for the initial electron density map with which the Cα backbone was traced. A MAD experiment using the Au derivative was done at SSRL, producing data > 97% complete for all four wavelengths. The model was partially built using the MAD phasing. Through the combination of the MAD and MIR phases a map (without model bias) of outstanding quality was created, greatly superior to either of the MIR or MAD maps alone. 90% of the sequence was assigned with this map. Use of phase extension and the wARP technique have produced a complete model at 1.57Å. Current work is directed to determining the protein/ganglioside complex structure.

This work was performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under contract no. W-7405-ENG-48

P09.04.027 METAL TRANSPORT IN PNEUMOCOCCAL VIRULENCE. Michael C. Lawrence, Patricia A. Pilling, V. Chandana Epa, Bettina L. Ferguson and Jeffrey J. Gorman, Biomolecular Research Institute, 343 Royal Parade, Parkville, Victoria 3052, Australia, and James C.Paton, Women's and Children's Hospital, North Adelaide, South Australia 5006, Australia.

The pneumococcal surface protein PsaA plays a role in the transport of zinc and/or manganese across the cell membrane in *Streptococcus pneumoniae*. The protein has been shown to be critical to the virulence of the organism: psaA$^-$ mutants are completely avirulent in mouse models [1]. We have recently determined the structure of PsaA via X-ray crystallography using multiple isomorphous replacement [2]. Details of the PsaA structure will be presented. The protein consists of two pseudo-symmetric α/β domains linked by a single "backbone" helix, and represents the first structure of an ABC-type receptor from a Gram-positive bacterium, and the first structure of a zinc/manganese transporter. A metal binding site is located between the protein domains and is formed by the side chains of two histidines, an aspartate and a glutamate. The site is occupied in the crystal, most likely by Zn^{2+}. The unexpected presence of the metal ion in this structure and the buried nature of its binding site suggests that the site is likely one of high affinity. Release of the metal ion will most likely therefore require a structural transition. We are currently seeking to determine the nature and structure of the metal-free form of the protein; details of progress towards this goal will also be presented.

P09.04.028 CRYSTAL STRUCTURE OF RAT TRANSTHYRETIN COMPLEX WITH TETRAIODOTHYROACETIC ACID AT 1.8A RESOLUTION. Andrzej Wojtczak, Tadeusz Muziol [1], Vivian Cody, Joseph R. Luft, Walt Pangborn [2], [1] N. Copernicus University, Gagarina 7, 87-100 Torun, Poland, [2] Hauptman-Woodward Medical Research Institute, Buffalo, NY 14203

Transthyretin is a tetrameric serum protein responsible for transporting about 20% of the circulating thyroxine (T4) in man, while in lower vertebrates, it is the only carrier. Structure activity data show that hormone metabolites have different binding affinities for TTR depending on their substitution pattern. Thus, the metabolite, tetraiodothyroacetic acid (T4Ac) is the strongest binder to TTR with T4 only 39%. Ligand binding is known to stabilize TTR tetramer formation, an important property in amyloid fibril formation, the cause of familial polyneuropathy, a fatal genetic disease characterized by single point mutations of TTR. Rat TTR is 85% homologous to the human protein and crystallizes in a tetragonal space group with a complete tetramer in the asymmetric unit. Human TTR crystallizes in an orthorhombic lattice and has a unique dimer in the asymmetric unit of the lattice. In order to understand the binding selectivity of thyroid metabolites and to understand the effect of point mutations on amyloid fibril formation, we carried out structural studies on rTTR and its hormone complexes. We report the crystal structure of rTTR complexed with T4Ac and compare these results with those of its hTTR complex. The current refinement of synchrotron low temperature data collected at CHESS for rTTR-T4Ac using XPLOR, is R=23.5%, Rfree = 30.0%, at 2.7A resolution and reveals disorder in the binding orientation of the ligand in the A/C binding domain, and a single population in the B/D domain. This model places the phenolic ring iodine atoms in the P3/P2' pockets on the opposite sides of the channel, while the diiodobenzyl iodines bind in the P1/P1' pockets, similar to that of rTTR-T4. The acetic acid carboxylate group forms a salt bridge to Lys-15 near the channel entrance. These data are similar to those observed in the hTTR-T4Ac complex which indicated multiple modes of binding for T4Ac in both binding domains. There was also indication of a second binding population with the metabolite bound deeper in the channel with a skewed diphenyl ether conformation rather than the expected twist-skewed conformation. Analysis of these data indicate that multiple modes of ligand binding are possible and provide insight into ligand binding selectivity and how sequence differences relate to amyloid formation.

P09.04.029 TETANUS TOXIN HC AND COGNATE CARBOHYDRATES. C.Fotinou [1], P.Emsley [1], N.Fairweather [2], C.Watts [3] and N.W.Isaacs [1], [1] Department of Chemistry, University of Glasgow, Glasgow, G12 8QQ, UK, [2] Department of Biochemistry Imperial College of Science, Technology & Medicine, South Kensington, London SW7 2AZ, [3]Department of Biochemistry, University of Dundee,MSI/WTB Complex, Dow Street, Dundee, DD1 5EH

Tetanus Toxin (TeNT) is produced by the bacteria *Closdridium tetani* in an attempt to kill its host by paralysis and suffocation.

TeNT is synthesised as a single polypeptide chain which undergoes cleavage to produce a mature toxin consisting of the N-terminal 50kD fragment linked via a disulphide bond to the 100kD C-terminal fragment (the H chain). The 50kD fragment of the C-terminal portion of the H chain (known as Hc or fragment-C) is responsible for ganglioside binding, which is essential for binding to neuronal cells.

TeNT undergoes trans-synaptic migration and targets the neuronal cells of the spinal cord. The mechanism consists of 4 stages: cell binding, vesicular internalisation, cytoplasmic translocation and cleavage of the substrate by the toxin L-chain. It is in order to start to understand these mechanisms that we have solved the structure of tetanus toxin Hc.

The structure consists of 2 domains, the N-terminal domain, which is a β sandwich and the C-terminal domain, which is a β-trefoil. The trefoil contains the putative ganglioside binding sites. It has been found that the gangliosides GT1b and GD1b have the highest binding affinity.

The determination of the Hc-ganglioside or Hc-cognate complexes will provide information about the type of interactions which occur during TeNT binding.

Small crystals of the Hc-GT1b complex have been grown. Data have been collected on crystals of Hc soaked in carbohydrates which are subunits of the ganglioside molecule.

P09.04.030 STRUCTURAL STUDIES OF THE HIGHLY AMYLOIDOGENIC TRANSTHYRETIN MUTANT G53S/E54D/L55S. Therese Eneqvist and Elisabeth Sauer Eriksson, Umea Center for Molecular Pathogenesis, Anders Olofsson and Erik Lundgren, Department of Cell and Molecular Biology, Umea University, S-901 87 Umea, Sweden

Transthyretin (TTR) is a homotetrameric plasma protein responsible for transport of the thyroid hormone thyroxine and retinol binding protein in complex with vitamin A. Mutations in TTR causes familial amyloidotic neuropathy (FAP), a lethal disease associated with motor- and sensor dysfunction. FAP is a form of amyloidosis, a group of diseases caused by structurally altered proteins that accumulate into insoluble fibrils and disrupt organ functions. There are at least 16 human proteins capable of forming amyloid, all different in structure and function. However, all amyloid fibrils contain cross-β structure and are associated with certain molecular components suggesting a more universal amyloidogenic fold. So far only the native conformations of amyloid proteins are known.

There are several structures of both native and mutant TTR and all show the native conformation. In order to detect the structural changes that lead to amyloid formation we are studying a group of highly amyloidogenic mutants of human TTR. These mutants spontaneously form aggregates in solution exposing epitopes that are recognized by amyloid-specific antibodies.

The crystal structure of the highly amyloidogenic G53S/E54D/L55S mutant is currently being refined at 2.3Å resolution. This mutant shows a new crystal form for transthyretin, the trigonal space group $p3_221$, with unit cell dimensions a = b = 58.31Å and c = 228.95Å.

P11.04.001 X-RAY CRYSTALLOGRAPHIC STUDY OF HUMAN HEMATOPOIETIC PROSTAGLANDIN D_2 SYNTHASE T. Inoue†, N. Okazaki†, Y. Kai†, D. Irikura§, O. Hayaishi§, M. Yamamoto‡, T. Kumasaka‡, Y. Urade§ †Dept. of Materials Chemistry, Osaka University, Suita, Osaka 565-0871, JAPAN §Dept. of Molecular Behavioural Biology, Osaka Bioscience Inst., Osaka 565-0874, JAPAN ‡Harima Inst., The Inst. of Physical and Chemical Research (RIKEN), Hyogo 679-5143, JAPAN.

Prostaglandins (PGs) are a widely distributed group of eicosanoids that are involved in the control of various defence and homeostatic mechanisms in the body. Hematopoietic prostaglandin (PG) D synthase is the key enzyme for production of the D and J series of prostanoids in the immune system and must cells. The crystal structure analysis of human PGD_2 synthase has been performed with MAD method by using the data for one Hg-derivative. Diffraction intensity data were collected at three wavelengths monochromatized by diamond trichromator with synchrotron radiation (BL45-XU beamline, SPring-8, Japan). The image data were recorded on RAXIS-IV imaging-plate system (Rigaku), and processed and scaled with *DENZO* and *SCALEPACK*. The program *MLPHARE* in the *CCP4* suite was used for refinement of atomic parameters and phase calculation. Phases were calculated up to 2.5 Å, and the overall figure of merit was 0.331 for 28,957 reflections. A density modification and NCS-averaging was carried out for phase improvement with the program *DM*. The electron density obtained after solvent density modification was of good quality and the chain could be traced. The atomic model was built using the program *O* and *TURBO*. Simulated annealing with *X-PLOR* 3.0 was carried out for the refinement. The present crystallographic *R*-factor at 2.3 Å resolution is 0.199 for 25,168 reflections between 10-2.3 Å with 201 water molecules. The free *R*-factor for the remaining 5% of the expected data within this resolution range was 0.212. The refinement at higher resolution is under progress.

P11.04.002 THE GROWTH AND ANALYSIS OF HUMAN THYROID PEROXIDASE CRYSTALS. E. Hendry and G. Taylor School Biomedical Sciences, University of St. Andrews, St. Andrews, Fife KY16 9TS, UK, and F. Grennan Jones, K. Ziemnicka, J. Furmaniak and B. Rees Smith, FIRS Laboratories, RSR Limited, Parc Ty Glas, Cardiff CF4 5DU, UK.

Thyroid peroxidase (TPO) catalyses the iodination and coupling reactions in thyroid hormone synthesis. It is also a major autoantigen in autoimmune thyroid disease and an important marker of thyroid disorders. Crystals of human TPO have been grown in order to determine the 3-D structure of the enzyme. The structure will help in the understanding of the enzyme mechanism, the nature of the interactions with autoantibodies, and the role of TPO in thyroid disease.

Recombinant immunoreactive TPO has been expressed to a high level in the High Five insect cell line [1]. The protein was purified by ion exchange chromatography and gel filtration. Crystals were grown in 12% PEG 4K at pH 6.75 with a TPO concentration of 18 mg/ml in a buffer of NaCl, PO_4 and KI.

Diffraction data were collected to 6 Å resolution processed using DENZO and SCALEPACK. The crystals belong to the 32 crystal class with unit cell dimensions of a=b=99.1 Å, c=216.0 Å and α=β=90°, γ=120°. A tentative molecular replacement solution has been found using myeloperoxidase as a phasing model, and an electron density map has been calculated to 7 Å resolution.

TPO is has a carbohydrate content of at least 12 kDa and the presence of multiple glycoforms or mobile carbohydrates chains may prevent high resolution diffraction. Work is underway to deglycosylate TPO, and, in addition, co-crystallisation with human monoclonal autoantibodies is being investigated.

The crystal structure of chondroitinase B from *Flavobacterium heparinum*, complexed with a dermatan sulphate disaccharide product, has been determined and refined (R_{work}=0.181, R_{free}=0.217) at 1.7Å resolution. This is the first structure of a product or substrate molecule bound to a polysaccharide lyase. The dermatan sulphate product consists of an unsaturated uronic acid, with the double bond between C4 and C5, linked β-(1→3) to N-acetylgalactosamine. The complex was obtained by soaking a native crystal of chondroitinase B in 30 mM disaccharide in cryoprotectant for 18h, followed by freezing directly in the nitrogen cold stream. Electron density corresponding to the disaccharide product was clearly visible in the initial difference map calculated at 1.7Å. The location of the disaccharide binding site is within the cleft formed by loops protruding from the β–helix, similar to that suggested for several polysaccharide degrading enzymes having the β–helix fold. Both direct and water mediated interactions contribute to product binding. A sulphate group at C-4 of N-acetylgalactosamine interacts directly with Arg364, and via a water molecule with Arg318. Arg318 and Arg363 interact with the carboxyl group of the uronic acid, and Arg271 stabilizes the galactosamine ring by interacting with the ring O atom and the C1 hydroxyl group. Comparison of the native and complex structures reveals no significant structural changes in the protein upon disaccharide binding. Further studies are in progress to elucidate the catalytic mechanism and substrate specificity of this enzyme.

P11.04.004 X-RAY STRUCTURE OF AN INHIBITOR PROTEIN AND LOCATION OF ITS SECOND REACTIVE SITE.
J.K.Dattagupta, A.Podder, C.Chakrabarti, U.Sen, S.Ravichandran and D. Mukhopadhyay, Crystallography & Molecular Biology Division, Saha Institute of Nuclear Physics, 1/AF Bidhannagar, Calcutta 700 064, India.

The crystal structure of an α-chymotrypsin inhibitor protein of Kunitz (STI) family isolated from winged bean (*Psophocarpus tetragonolobus*) seeds, will be reported. This is a single polypeptide chain having a molecular weight of 20,244 Da with 183 amino acid residues. The structure of the protein has twelve antiparallel β-strands with connecting loops arranged in a β-trefoil fold common to other homologous serine protease inhibitors in this family, like soybean trypsin inhibitor, *Erythrina caffra* trypsin inhibitor, proteinase K inhibitor from wheat germ and also winged bean albumin belonging to the same family, as well as to some non-homologous functionally unrelated proteins like Interleukin-1α, Interleukin-1β, Human fibroblast growth factor, Abrin-a sugar complex, Interleukin-1 receptor antagonist and Amaranthin. This inhibitor protein was found to have the unique property of inhibiting bovine α-chymotrypsin in the molar ratio 1:2 at higher concentrations of the enzyme indicating that the inhibitor has two reactive sites. The conformation of the first reactive site loop in the structure is found to be stabilized through hydrogen bonds mainly formed by the side-chain of Asn 14, which intrudes inside the cavity of the reactive site loop, with the side-chain and main-chain atoms of some residues in the loop region. Analysis of the crystal structure of the protein led to the location of the second reactive site, about which no prior biochemical information was available. This site was identified mainly on the basis of a best fit structural study of the available canonical conformation of the serine protease inhibitor reactive sites. The structural results have also been used to understand the mechanism of inhibition against chymotrypsin at the molecular level. X-ray structures of the recombinant and two mutant forms of the inhibitor protein are also being determined in our laboratory.

P11.04.005 X-RAY STRUCTURAL STUDIES WITH HUMAN THIOREDOXIN PEROXIDASE.
E. Schröder, M. I. Isupov and J. A. Littlechild, Departments of Chemistry and Biological Sciences, University of Exeter, Exeter, EX4 4QD, UK.

Thioredoxin Peroxidase-1 (TDX1), previously known as Natural Killer Enhancing Factor-B, is an intracellular member of the peroxiredoxins, an emerging family of antioxidant enzymes with monomeric masses of 20-29kDa. Their biological interest lies in their ability to combat oxidative stress by degrading hydrogen peroxide and organic hydroperoxides to water or to the corresponding alcohol. Over the last few years, peroxiredoxins have been shown to play roles in tyrosine kinase signalling and in apoptosis. The ability of TDX1 to prevent the attachment of monocytes to endothelial cells in response to oxidised lipoproteins suggests that this enzyme may help combat the effects of atherosclerosis. In common with other peroxiredoxins, TDX1 readily forms disulphide-linked dimers under oxidising conditions and oligomers under reducing conditions with an approximate molecular mass of 350kDa. A cysteine located close to the N-terminus is completely conserved among all PRX enzymes and is essential for catalysis, although most peroxiredoxins also contain a conserved cysteine located towards the C-terminus, which is a requirement for their regulation by thioredoxin. Non-recombinant human TDX1 has been purified to homogeneity from red blood cells and two crystal forms have been grown by vapour diffusion: monoclinic $P2_1$ crystals (a = 88.9 Å, b = 107.0 Å and c = 119.5 Å, and β = 110.9) and orthorhombic $P2_12_12_1$ crystals (a = 57.2 Å, b = 185.3 Å and c = 226.5 Å). The asymmetric unit in both crystal forms is likely to be oligomeric, containing 6-14 molecules (assuming a solvent content of 30-75%), which is consistent with the tendency of TDX1 to form discrete oligomers in solution. The diffraction from both crystal forms extends to beyond 2.0 Å resolution using synchrotron radiation. Complete native data sets have been collected on the X11 Hamburg beam-line under cryogenic conditions to 1.8 Å and 2.7 Å resolution from monoclinic and orthorhombic crystals respectively. A search for heavy atom derivatives is currently in progress.

P11.04.006 PROBING THE STRUCTURAL BASIS OF PROTEIN THERMOSTABILITY.
H. Walden and G.L. Taylor School Biomedical Sciences, University of St. Andrews, St. Andrews, Fife KY16 9TS, UK, and R. Hensel Dept. Microbiology, FB9, Universität-GH Essen,, Universitätsstrasse 5, 45117 Essen, Germany, and G.S.Bell, D.W. Hough and M.J. Danson, School Biological Sciences, University of Bath, Claverton Down, BA2 7AY,, UK.

Triosephosphate isomerase (TIM) is a glycolytic enzyme which catalyses the interconversion of glyceraldehyde-3-phosphate and dihydroxyacetone phosphate. All the bacterial and eukaryal TIM sequences published to date are homomeric dimers and each subunit consists of an eight stranded αβ-barrel domain. However, the TIM sequence of the hyperthermophilic Archaeon *Pyrococcus woesei*, which grows at an optimu temperature of 100°C, is a homotetramer [1]. Another difference is the length of the deduced protein sequence - bacterial and eukaryal TIMs are 240-260 residues in length, while the *P. woesei* TIM comprise only 224 residues.

Preliminary crystallographic studies of native *P. woesei* TIM have been carried out [2], and to date, molecular replacement

has been unsuccessful. Attempts are currently being made at heavy atom isomorphous replacement.

There are several TIM crystal structures available from bacterial and eukaryal sources, enabling a comparative study of mesophilic and thermophilic TIMs, which should provide some insight into the nature of protein thermostability.

2. Bell, G.S., Russell, R.J.M., Kohlhoff, M., Hensel, R., Danson, M.J., Hough, D.W. & Taylor, G.L. (1998) *Acta Cryst.* D**54** 1419-1421.

P11.04.007 CRYSTAL STRUCTURE AND PRIMARY SEQUENCE OF *THERMOASCUS AURANTIACUS* XYLANASE: BASIS OF THERMOSTABILITY. R. Natesh, P. Bhanumoorthy, P.J. Vithayathil, K. Sekar, S. Ramakumar, M.A. Viswamitra, Department of Physics / Bioinformatics Centre, Indian Institute of Science, Bangalore-560012, India.

Thermoascus aurantiacus xylanase is a thermostable enzyme which hydrolyses xylan, a major hemicellulose component in the biosphere. Earlier biochemical studies on the protein extracted from a local strain of the fungus reveal that the enzyme retains its activity even at 70°C and hence is likely to be industrially relevant. More than 10 salt bridges which together with a disulfide bond between Cys 255 and Cys 261 might be contributing to the thermostability of the protein. To our knowledge we observe for the first time in F/10 family xylanase structures, a proline in the middle of a helix. In addition we also observe a unique salt bridge between Arg 124 and Glu 232 which links sequencially separated segments of the protein and might be contributing to thermostability. Our study suggests that in addition to the number of interactions their location is also an important factor for thermostability.

Intensity data were collected from crystals that belong to space group $P2_1$ with a = 41.7, b = 68.1, c = 51.4 Å and β = 113.6°, Z = 2. The structure was solved by molecular replacement using the ***Streptomyces lividans*** xylanase as a search model. The amino acid sequence was determined from electron density maps aided by multiple alignment of related xylanase sequences. The sequence thus obtained provides a correction to the sequence reported earlier based on biochemical methods. The final 1.8 Å resolution refined protein model with 301 residues and 266 water molecules has a R of 16.0 % and R_{free} of 21.1 % with good stereochemistry. The single polypeptide chain assumes $(\alpha/\beta)_8$ TIM-barrel fold and belongs to F/10 family of glycoside hydrolases. The active site consists of two glutamates located at the C-terminus end of β-barrel conforming to the double displacement mechanism for the enzyme action.

P11.04.008 MECHANISM OF PHOSPHORYL HYDROLYSIS; WHAT MAKES AN ENZYME A GOOD CATALYST? P.Heikinheimo[α], V.Tuominen[α], R.Lahti[β], B.S.Cooperman[γ] & A.Goldman[α,β] [α]Turku Centre for Biotechnology, P.O. Box 123, FIN-20521 Turku, Finland, [β]Department of Biochemistry, University of Turku, FIN-20014 University of Turku, Finland, [γ]Department of Chemistry, University of Pennsylvania, Philadelphia, PA 19104, USA

The detailed mechanism and quantum mechanical basis for enzymatic catalysis remains incompletely understood[1]. What makes enzymes good catalysts for a reaction? Is it 'orbital steering' and bringing the reactants together in the right orientation or do enzymes also provide e.g. short, high energy hydrogen bonds. Are there other explanations?

Inorganic pyrophosphatases (PPases) provide a good working model to study the mechanism of phosphoryl hydrolysis. They catalyse the hydrolysis of inorganic pyrophosphate (PP_i) to two phosphate molecules by extensive use of metal ions[2]. The kinetics and the pH dependence of the reaction are thoroughly studied[3,4] and in addition to the resting state and mutant structures[2,5], a refined structure of the substrate/product equilibrium around the transition state is available at 1.1 Å resolution. This structure allows us to address issues of H-bond length and orbital steering directly. We have evidence for ultra-short H-bonding between the proposed general base (D117) and the nucleophile (Wat1), explaining their matching pK_a's, but our structures show that 'orbital steering' or transition state stabilisation are *not* part of the catalytic mechanism. We also see specific binding of the product, which suggests that lowering the substrate restoring forces increases the probability of each transition state producing product. This, in conjunction with subtle product release mechanisms, affords diffusion controlled catalysis in this class of phosphoryl hydrolysing enzymes, and we propose a standard model for the mechanism of biocatalysis.

P11.04.009 A NEW CLASS OF INORGANIC PYROPHOSPHATASE. A.J. Milner, T.W. Young, S.A. White, School of Biochemistry, University of Birmingham, Edgbaston, Birmingham, West Midlands, B15 2TT.

Inorganic pyrophosphatase (PPase, E.C.3.6.1.1) is a ubiquitous enzyme which plays an important role in overall cell metabolism (Chen et al, 1990). It has recently been reported that the PPase from Bacillus subtilis has been purified and that its amino-acid sequence (Young et al, 1998), subunit molecular mass and requirement for manganese ions make it different from the PPases isolated from other organisms (Kuhn and Ward, 1998). Subsequent work has resulted in the proposition that this protein belongs to a new class of PPase (class C). This classification is based on sequence and activity differences between the B. subtilis PPase and the PPases that have been characterised from other prokaryotes (class A) and eukaryotes (class B). Crystals, grown by hanging drop vapour diffusion, reach a maximum size of 0.2mm in the largest dimension. A preliminary data set has been collected, analysis suggests an orthorhombic unit cell (a=81.4 Å, b=133.3 Å, c=155.2 Å, α=β=γ=90°) with c222 symmetry. The latest results will be presented.

P11.04.010 ADC ESTERS, AUTOCLEAVAGE AND CATALYSIS: WHAT THE STRUCTURES SAY. F.von Delft[1], A.Albert[1], V.Dhanaraj[1], U.Genschel[2], M.K.Rajmee[2], M.Witty[2], R.Pulido[3], T.L.Blundell[1], A.G.Smith[2], C.Abell[3]. (**1**) Biochemistry, Cambridge University, CB2 1GA, UK (**2**) Plant Sciences, Cambridge University, CB2 3EA, UK (**3**) Chemical Laboratory, Cambridge University, CB2 1EW, UK.

The 2.2 Å crystal structure[1] of *E. coli* Aspartate Decarboxylase has, for the first time, revealed the structure of an ester intermediate, produced during the enzyme's auto-cleavage. Self-catalyzed backbone N- to O/S-acyl shifts, resulting in a (thio-)ester intermediate, are the first step in the maturation of several diverse self-cleaving biological systems. In ADC, this leads to formation of a catalytic pyruvoyl co-factor. The structure is homo-tetrameric: three subunits appear fully processed while the fourth contains the uncleaved chain containing the ester. This intermediate is a trapped species, since residues necessary for ester cleavage (T57/Y58) seem too far removed for effective catalysis in the uncleaved subunit. We propose that self-cleavage occurs cyclically around the tetramer, as a sequential and negatively co-operative process: successive subunits cleave more slowly.

Two crystal structures of ADC with bound substrate analogues (α-methylaspartate at 1.7 Å and β-alanine at 1.9 Å resolution) confirm the initial model of substrate binding and catalysis. The binding cavity is located between two subunits, and the substrate binds as a Schiff base to a pyruvoyl group in the *trans* conformation. R54 and W47 from the adjacent subunit form, respectively, a salt bridge and an aromatic stacking interaction with the substrate's β-carboxylate group. This positions the negatively charged departing α-carboxylate group in a hydrophobic pocket formed by Y58, I60 and the pyruvoyl methyl group, thus driving α-decarboxylation. The resulting α-carbanion is stabilised by π-bond delocalisation across the Shiff base-pyruvoyl system, and is most likely protonated by a bound water, connected to the solvent *via* the H-bonding network of G24 and Y57, and K9 and H11 from the adjacent subunit.

P11.04.011 FERROCHELATASE IN COMPLEX WITH AN INHIBITOR, N-METHYL MESOPORPHYRIN. D. Lecerof, M. Fodje and S. Al-Karadaghi [1] M. Hansson, A. Hansson [2] [1] Dept. of Molecular Biophysics, Lund University, Box 124, 221 00 Lund, Sweden [2] Dept of Biochemistry, Lund University, Box 124, 221 00 Lund, Sweden.

Ferrochelatase is the terminal enzyme in the haem synthesis pathway. It catalyses the insertion of a ferrous ion into protoporphyrin IX forming haem b. In humans, the autosomal dominant disease protoporphyria is due to the reduced activity of ferrochelatase. Here we present the structure of ferrochelatase from Bacillus Subtilis in complex with N-methyl mesoporphyrin (N-MMP) refined to 2.1 Å, thereby providing the basis for a deeper understanding of the mechanisms of enzyme catalysed metal chelating.

The active site of ferrochelatase consists of a deep cleft in which N-MMP is bound with its carboxyl groups reaching out to the surface. Compared with the native structure [1], the loops which interact with the incoming inhibitor in the active site have moved by about 2-3 Å, in order to make room for the inhibitor. The methylated imidiazol ring of N-MMP is tilted by about 40 degrees with the methyl group close to His183, suggested earlier to be involved in catalysis. Besides this pronounced tilting, the rest of the N-MMP is not plane, indicating a strained conformation of the molecule. As previous studies of antibodies elicited to N-MMP showed catalytic activity at rates up to 10 % of ferrochelatase rate [2], these results suggest that the bound conformation indeed is that of a transition state analogue. The structures of the complexes of Co2+, Cu2+ and Zn2+ with the apo-enzyme and the enzyme:N-MMP complex have also been studied. The results show 3 different metal binding sites in ferrochelatase. The implications of these findings to the mechanism of porphyrin metallation will be discussed.

P11.04.012 CRYSTAL STRUCTURE OF AROMATIC AMINO ACID AMINOTRANSFERASE FROM *Pyrococcus horikoshii*. K. Harata, W.-D. Schubert,* E. Matsui, K. Ishikawa, and I. Matsui, National Institute of Bioscience and Human-Technology, Tsukuba, Ibaraki 305-8566, Japan. *Present address: Institut für Kristallographie, Freie Universität, Takustr. 6, 14195 Berlin, Germany

Amino acid aminotransferase, which has pyridoxal-5'-phosphase (PLP) as a co-enzyme, is an enzyme to transfer the amino group from an amino acid to an ap-keto acid. We have obtained the enzyme (ArAT) specific for aromatic amino acids from *Pyrococcus horikoshii*, a hyperthermophile which grows at near 100º C. ArAT with the optimum temperature of *ca*. 90º.C consists of 389 amino acids. Crystals were obtained from 3M 1,6-hexane-di-ol solution with pH 7.5 containing 10mM $MgCl_2$. Cell dimensions were a=64.01, b=124.87, and c=128.78 Å, and the space group was $P2_12_12_1$ with Z=8 (V_m=2.93 Å^3/Da). X-ray diffraction data were collected to 2.1 Å resolution on an Nonius FAST diffractometer equipped with FR571 rotating anode generator. The structure was solved at 3 Å resolution by the MIR method using four heavy atom derivatives and refined at 2.1 Å resolution to the R-value of 0.185 (R_{free}=0.253).

Two molecules in the asymmetric unit are related with a local twofold axis and the active site consists of amino acid residues from the two molecules. The main chain folding is similar to the structure of aspartate aminotransferase from *E. coli* and some of amino acid residues in the active site are conserved in spite of low sequence similarity. The PLP molecule is bonded to Lys232 and the pyridine ring is in the face-to-face contact with the phenyl group of Phe121.

P11.04.013 CRYSTALLOGRAPHIC STUDYES OF ASPARTATE AMINOTRANSFERASE FROM A THERMOPHILIC *CYANOBACTERIUM*. K. Hamada[1], K. Nozawa[1], Y. Sawa[2], Y. Mezaki[3], Y. Katsuya[3], T. Kumasak[4] and M. Yamamoto4, [1]Interdisciplinary Faculty of Science and Engineering, Shimane University, Matsue 690-8504, Japan, [2]Faculty of Life and Environmental Science, Shimane University, Matsue 690-6504, Japan, [3]Hyogo Prefectural Institute of Industrial Research, SR-laboratory, Kamigori, Hyogo 678-1201, Japan, [4]RIKEN, Harima Institute, Mikazuki, Hyogo 679-5143, Japan.

Aspartate aminotransferase (AspAT) is a pyridoxal 5'-phosphate (PLP)-dependent enzyme and catalyzes the reversible transfer of the amino group of aspartate to 2-oxogulutarate by the ping-pong Bi Bi mechanism. AspAT from a thermophilic cyanobacterium, *Phormidium lapideum* (*Pl*AspAT) is a thermophilic and thermostable enzyme which retains its structure and reaches maximal activity at 80 °C. AspAT from *P. lapideum* shares with mesophilic eukaryotic and bacterial counterparts a large number of catalytically significant feature. However, the sequence homology of *Pl*AspAT is not exceeding 20% against mesophilic eukaryotic and bacterial enzymes, and that is 40% level against thermophilic bacterial enzymes. The differences observed, which reflect the evolutionary distance between Archaea, Eukarya, Bacteria, may be able to account for the enzyme adaptation to high temperatures. *Pl*AspAT expressed in *E. coli.* containing the plasmid of *Pl*AspAT was purified, and crystallised with the essential cofactor of PLP by the hanging drop technique using ammonium sulfate as precipitant. Of three different crystal forms of monoclinic, tetragonal, and rhombic observed, the monoclinic crystals were most suitable for X-ray structure analysis. The crystals belong the monoclinic space group C2 with unit cell dimensions of a = 122.1 , b = 110.8, c = 87.8 Å and b = 97.1°. A V_m value of 3.30 Å^3/Da indicated that a dimmer was contained in the asymmetric unit. Native data set to 2.5 Å resolution was collected using synchrotron radiation at the Photon

Factory, KEK, and SPring-8. The structure analysis by molecular replacement method is now in progress.

P11.04.014 ENTROPIC ALLOSTERIC EFFECT FOUND TROUGHT THE X-RAY STRUCTURE OF THE GLUCOSAMINE 6-PHOSPHATE DEAMINASE FROM *E. coli*., E. Horjales, S. Morales and E. Rudiño-Piñera, Molecular Recognition and Biostructure Department, Biotechnology Institute, National Autonomous University of Mexico (UNAM), Av. Universidad No. 2001, Col. Chamilpa, CP. 62210, Cuernavaca, Morelos, MEXICO. E-mail: horjales@ibt.unam.mx

The allosteric transition between the R and T forms in allosteric enzymes can be explained through conformational changes between both conformers, but the use of high resolution diffraction data (which validate the use of temperature factors B) shows in our case the different vibrational components between the R and T forms centred in particular in the active site lid (residues 158-185). In the present case the protein Glucosamine 6-phosphate deaminase (which catalyses the reversible reaction between glucosamine 6-phosphate and fructose 6-phosphate and ammonium) structure was solved in presence of trace amounts of its allosteric activator (N-acetyl glucosamine 6-phosphate (NAG6P)) , giving a final R=0.214 (R_{free}=0.264) at 2.8 Å resolution. This native R form presents the NAG6P only in the allosteric site, and b values below 70 with a continuous electron density map at 1.0 σ in the lid.

In other hand, the protein crystallographic structures solved from the T and R mutants Y254F (which kinetically shows its importance as two-way switch mechanism in the allosteric transition (1)) present the same structure as its respective native molecule, in the case of the Y254F R form a NAG6P is ligated only in the allosteric site (with a free active site). The mutants Y254F R and T forms were solved at 2.15 Å and 1.94 Å resolution, with R=0.216 (R_{free}=0.261) and R=0.212 (R_{free}=0.228) respectively. Our results prove that the lid is clearly less mobile in R conformer. The Y254F mutant also shows that the kinetical differences with the native form are only explained with an entropic component in the allosteric transition.

Acknowledgements: We wish to thank Dr. Mario Calcagno for supplying the purified protein, Sonia Rojas-Trejo for technical assistance, the SSRL for data collection time. This study has been supported by DGAPA-UNAM (Grant IN-201295). S. Morales and E. Rudiño are supported by CONACyT.

P11.04.015 CRYSTAL STRUCTURE OF AN E96A MUTANT OF GLUCOSE DEHYDROGENASE FROM *BACILLUS MEGATERIUM* Keizo Yamamoto[1], Masami Kusunoki[2], Genji Kurisu[2], Itaru Urabe[3], and Shiro Tabata[1], [1]Department of Chemistry, Nara Medical University, Kashihara, Nara 634-0813, [2]Institute for Protein Research, Osaka University, Suita, Osaka 565-0871, [3]Department of Biotechnology, Graduate School of Engineering, Osaka University, Suita, Osaka 565-0871, Japan

Glucose dehydrogenase from *B.megaterium* is a tetrameric enzyme with four identical subunits. The enzyme is inactivated at pH 9.0 due to the dissociation of the tetramer into inactive monomers, and the monomers reassociate at pH 6.5 into the fully active tetramer. The E96A mutant is in the tetrameric state even at pH 9.0 and the activity is 85% of that kept at pH 6.5. In order to elucidate the mechanism of increasing stability of the intersubunit interaction and/or tertiary structure of the protomer, we have been carring out the X-ray studies of the E96A mutant.

The enzyme was crystallized by the hanging-drop vapor diffusion method with PEG2000 as a precipitant, followed by a microseeding technique. The crystals belongs to the monoclinic space group C2 with cell dimensions of a=121.96 Å, b=66.64 Å, c=120.06 Å and β=93.44°, contains four subunits per asymmetric unit. Diffraction data were collected on Weissenberg camera with synchrotron radiation at the BL18B in Photon Factory, KEK, Japan. Molecular replacement was used to determine an initial phase set. Refinement is in progress using X-PLOR and the current R-factor is 0.24 for data to 2.5 Å resolution.

P11.04.016 CRYSTALLIZATION OF OROTIDINE 5'-MONOPHOSPHATE DECARBOXYLASE P.Harris, J.-C.N.Poulsen, S.Larsen, Centre for Crystallographic Studies, University of Copenhagen, Denmark and K.F.Jensen, Center for Enzyme Research, University of Copenhagen, Denmark.

Orotidine 5'-monophosphate decarboxylase (ODCase) catalyses the decarboxylation of orotidine 5'-monophosphate (OMP) to uridine 5'-monophosphate (UMP), the sixth and last step in the *de novo* biosynthesis of UMP (a precursor of other pyrimidine mononucleotides). At physiological temperatures ODCase enhances the rate of reaction by a factor of 10^{17}, thus it is the most proficient enzyme known [1]. Despite the extensive enzymological studies of ODCase [2] no information is available on the three dimensional structure of this enzyme, so important in pyrimidine biosynthesis.

Trigonal crystals are obtained using Na-formate as precipitant. Cryocooled, these crystals diffracted to 2.8 Å at the BW7B beamline at the EMBL, Hamburg. The space group is $P3_1$ and the cell dimensions are $a = b = 142.52$ Å and $c = 105.12$ Å which indicates 4, 6 or 8 molecules in the asymmetric unit, corresponding to 75, 62 or 50 % solvent content, respectively.

A new crystal form, where an inhibitor is bound, has been obtained using PEG4000 as precipitant. At the BL711 beamline at MAXII in Lund, Sweden, these crystals diffracted to at least 2.2 Å. The cell dimensions are $a = 61.85$ Å, $b = 96.77$ Å and $c = 148.33$ Å and the space group is identified as $P2_12_12_1$ indicating two molecules in the asymmetric unit for a solvent content of 69%.

Progress of the structure solution will be presented.

P11.04.017 STRUCTURE OF AN EXOGLUCANASE COMPLEXED WITH CONDURITOL B EPOXIDE FROM A 50μ CRYSTAL USING MONOCAPPILARY OPTICS. JN Varghese, A van Donkelaar, Biomolecular Research Institute, 343 Royal Parade, Parkville, Victoria 3052 Australia, M.Hrmova, GA Fincher , Dept. of Plant Science, Waite Institute, University of Adelaide, Urrbrae, South Australia 5064, and DX Baliac, Z Barnia, Dept. of Physics, University of Melbourne, Parkville, Victoria 3052, Australia.

The 3-D structure of β-D-exohydrolase from Barley seed has been determined previously by X-ray crystallography (Varghese et al. 1999). The native structure was found to have a glucose moiety bound in a deep pocket formed by an intimate association of two domains of the protein. The structure presented in this abstract confirms the location of the active site of the molecule, by showing that conduritol B epoxide displaces the bound glucose and forms a covalent bond with one of the proposed catalytic acids (E491). This reaction is consistent with hydrolytic mechanism of this glucose hydrolase.

The X-ray data were collected from a frozen 50μ crystal mounted on a MAR180 imaging plate detector, using an Elliot GX20 running at 33kV and 20mA using a 100μ cup, and an ellipsoidal glass monocapillary (Baliac et al. 1996) with a 100μ focus at the crystal. This system delivers an intensity 28 times that

of an equivalent unfocussed beam at the specimen, allowing micro-protein X-ray data to be collected using laboratory sources.

P11.04.018 THE CRYSTAL STRUCTURE OF 1-AMINOCYCLOPROPANE-1-CARBOXYLIC ACID DEAMINASE FROM YEAST. M. Yao, H. Sugimoto, T. Ose, A. Horiuchi, A. Nakagawa and I. Tanaka, Graduate School of Science, Hokkaido University, Sapporo, Japan, D.Yokoi, T.Murakami and M. Honma, Graduate School of Agriculture, Hokkaido University, Sapporo, Japan, S. Wakatsuki, ESRF, Grenoble, France.

1-Aminocyclopropane-1-carboxylic acid (ACC) deaminase, a pyridoxal phosphate(PLP)-dependent enzyme found in microorganisms, catalyzes a reaction of cleavage ACC to α-ketobutyrate and ammonia by cyclopropane ring-opening. ACC is a key intermediate in the biosynthesis of a plant hormone ethylene which affects diverse growing and fruit ripening. Interestingly, introduction of ACC deaminase gene in plants was reported to reduce the production of ethylene and delay ripening progression of fruits, although ACC deaminase has never been found in higher plants with the exception of transgenic plants. The three dimensional structure of ACC deaminase from yeast *Hansenula saturnus* (yACCD) was determined by MAD method using mercury atoms as anomalous scatterer.

The two crystal forms were obtained for mercury derivative of yACCD by co-crystallization. The 2.0Å native data and 2.8Å MAD data of the orthorhombic form and 2.5 Å MAD data of the trigonal form were collected using synchrotron radiation at the ESRF of France and Photon Factory of Japan, respectively. Initial phasing was done independently for the two forms. The model was built based on 2.8Å electron density map after improvement by non-crystallographic symmetry averaging of multiple crystal forms. The molecular dynamic refinement is currently underway at 2.0Å resolution using native data.

The structure of yACCD can be divided into two different size domains (small domain and PLP-binding domain). Both domains have open twisted α/β−sheet structures. The PLP co-enzyme is positioned close to the big internal gap between the two domains and covalently bound to Lys54.

P11.04.019 HUMAN AND BACTERIAL GLUCOSE 6-PHOSPHATE DEHYDROGENASE: IMPLICATIONS OF SPECIFIC STRUCTURAL CHANGES. Shannon W.N. Au, Veronica M.S. Lam, Department of Biochemistry, University of Hong Kong, H. Richard Levy, Department of. Biology, Syracuse University, Syracuse, NY 12344, USA, Sheila Gover & Margaret J. Adams, Laboratory of Molecular Biophysics, Department of. Biochemistry, University of Oxford, OX1 3QU, UK.

G6PD catalyses the first committed step of the pentose phosphate pathway, oxidising glucose 6-phosphate to its δ-lactone. In the human erythrocyte, the reduced coenzyme NADPH generated by this step protects against oxidative stress. In bacteria such as *Leuconostoc mesenteroides,* the enzyme is also required for catabolism for which it utilises NAD^+. Our 2Å structure of the dual-specific *L. mesenteroides* apo-enzyme dimer showed how residues conserved in all known G6PD sequences could play a crucial role in binding coenzyme and substrate. Kinetic studies of site directed mutants have confirmed our predictions and complement our structural studies of different binary and ternary complexes aimed at defining the molecular basis of the two modes of enzyme action.

Human G6PD deficiency is an extremely common enzymopathy; more than 100 point mutations have been identified, some giving rise to severe clinical symptoms. Dimers and tetramers of the erythrocyte enzyme are in a functional equilibrium. We have a 3Å structure of the commonest Chinese deficient variant, Canton (R459L), and a 2.6Å structure of an active, more thermally stable, mutant constructed by deletion from the normal human enzyme of the 25 N-terminal residues absent in bacteria. Both form tetramers which are "dimers of dimers", but there are significant local changes of conformation between the two, and from the bacterial structure. Plasmids have been constructed in which the point mutations for the Canton and Kaiping (R463H) variants have been combined with the N-terminal deletion. By extending to higher resolution and using crystals of these mutants, we aim to understand the structural bases of deficiency.

P11.04.020 CRYSTALS OF MALTOSE TRANSACETYLASE. L. Lo Leggio and S. Larsen, Centre for Crystallographic Studies, Copenhagen University, Universitetsparken 5, 2100 Copenhagen Ø, Denmark and K. W. Harlow and G. J. Abel, Danisco Biotechnology, Langebrogade 1, Box 17, 1001 Copenhagen K, Denmark

Maltose transacetylase (Mac) is an *E. coli* enzyme which transfers an acetyl group from acetyl-CoA to several sugar substrates. The primary sequence of Mac has an imperfect tandem-repeated hexapeptide motif [1] which strongly suggests that the protein will have the left-handed parallel β-helix architecture already observed in three acyl-transferases and a carbonic anhydrase. Two crystal forms have been characterized by collecting data at BL711 at the MAX II synchrotron in Lund, Sweden. Other crystallization conditions are being optimized.

Hexagonal needles with apparent P622 symmetry are grown reproducibly using ammonium sulphate as precipitant. The cell edges were a=b= 97.8 Å and c=90.3 Å and a 1.53 Å data set was collected at 100 K. However there is some indication of merohedral twinning for these crystals, so that P622 may not be the real space group.

A second crystal form has been grown using PEG as precipitant with MPD as an additive. We were able to collect data to 3.1 Å (100 K) at MAX II. The crystals belong to space group R3 with cell edges a=b= 156.0 Å and c= 142.4 Å (in hexagonal setting). Four to ten monomers of Mac in the asymmetric unit produce values of V_m within the range commonly observed for proteins. The progress in the structure solution of Mac will be described.

P11.04.021 THE CRITICAL ROLE OF SOLVENT MOLECULES IN THE INDUCED FIT-MECHANISM OF THE ANTIBIOTIC TARGET MUR-A. S. Eschenburg, Max-Planck Institute for Medical Research, Department of Biophysics, 69120 Heidelberg, Germany, and E. Schönbrunn, Colorado State University, Department of Biochemistry and Molecular Biology, Ft. Collins Co80523, USA, and N. Amrhein, Swiss Federal Institute of Technology, Institute of Plant Sciences, 8092 Zurich, Switzerland.

MurA (UDP-N-acetylglucosamine enolpyruvyltransferase, EC 2.5.1.7) initiates the biosynthesis of the heteropolymer murein, the major structural element of the bacterial cell wall. It catalyzes the transfer of the intact enolpyruvyl moiety of phosphoenolpyruvate (PEP) to the 3-hydroxyl of UDP-N-acetylglucosamine (UDP-GlcNAc). This mechanistically unusual reaction is associated with substantial conformational changes in the enzyme.

The two-domain protein MurA is built up by the six-fold repetition of a folding unit consisting of two parallel α-helices and a four-stranded β-sheet [1]. The catalytically essential residue Cys115 is located in a flexible loop, which, in the course of the enzymatic reaction, moves about 20 Å towards the inter-domain section [2]. The large conformational changes upon binding of substrates and/or the naturally occuring inhibitor fosfomycin are predominantly mediated by UDP-GlcNAc [3].

We characterized the dynamics of a number of single-site mutants of MurA by various techniques. The high resolution X-ray crystallographic analysis of wild-type MurA (d_{min} 1.55 Å) and mutants with altered dynamic properties (d_{min} 1.70 Å to 1.90 Å) revealed that the arrangement of solvent molecules in the cleft between the two globular domains is critical for the motility of the enzyme and its induced fit mechanism.

P11.04.022 CRYSTAL STRUCTURE OF LUCIOLA CRUCIATA FIREFLY LUCIFERASE COMPLEXED WITH MgATP. T. Nakatsu and H. Kato, Institute for Chemical Research, Kyoto University, Uji, Kyoto 611-0011, Japan and K. Hirokawa, N. Kajiyama and E. Nakano, Research & Development Division, Kikkoman Corporation. Noda, Chiba 278-8601, Japan

The crystal structure of Luciola cruciata firefly luciferase complexed with MgATP was determined by molecular replacement using unliganded luciferase from Photinus pyralis (sequence similarity is 67 %) as a search model. The overall structure consists of two domains. Each domain is similar that of Photinus pyralis luciferase, but a conformational change by a domain rotation with about 90 degree was caused by MgATP binding.

Firefly luciferase catalyzes the luminescence reaction through the oxidation of d-luciferin in the presence of MgATP, and molecular oxygen. In the first step, d-luciferin is reacted with MgATP to form an enzyme-bound luciferyl adenylate and pyrophosphate. Then the luciferyl adenylate intermediate is oxidized by molecular oxygen, and produce AMP, CO2 and an electronically excited state of oxyluciferin, which subsequently returns to the ground state with concomitant emission of visible yellow-green light. The enzyme efficiently converts chemical energy into light with a quantum yield of 0.88.

The luciferase from Luciola cruciata is functional as a monomer of molecular weight of about 60K with 548 amino acids. The T217I mutant enzyme was crystallized by hanging drop vapor diffusion method using PEG4000. The crystals belong to the space group $P\,2_12_12_1$ with cell constant a = 58.1 Å, b = 181.7 Å and c = 54.2 Å,. The intensity data of crystals were collected on a RIGAKU R-AXIS IIc to 2.3 Å resolution. The crystal structure was solved by molecular replacement using AMORE. The initial model was rebuilt by fitting correct sequence into the $2F_o$- F_c electron density map. The refinement of the model was carried out with REFMAC and X-PLOR 3.851. Current molecule includes 531 residues and the R and R_{free} values are 0.23 and 0.29 respectively at 12.0 - 2.5 Å resolution. The further refinement is in progress.

P11.04.023 STRUCTURAL STUDIES ON CARBAMOYL PHOSPHATE SYNTHETASE. James B. Thoden and Hazel M. Holden, Department of Biochemistry, University of Wisconsin, Madison, WI, 53705, USA, and Frank M. Raushel, Department of Chemistry, Texas A&M University, College Station, TX, 77843, USA

Carbamoyl phosphate synthetase (CPS) from *Escherichia coli* catalyzes the formation of carbamoyl phosphate from glutamine, bicarbonate, and two molecules of MgATP. Carbamoyl phosphate is used in the first steps of two biosynthetic pathways. In one it is coupled with aspartate in a reaction catalyzed by aspartate transcarbamoylase and is eventually incorporated into pyrimidine nucleotides. In the other it reacts with ornithine and is used to produce arginine and/or urea.CPS is a heterodimeric enzyme composed of a small (40K) glutaminase subunit and a large (120K) synthetase subunit. Glutamine is hydrolyzed in the small subunit to produce ammonia. The ammonia is then used by the large subunit to produce carbamoyl phosphate by a set of reactions at two active sites. The ammonia is first converted to carbamate by reaction with carboxyphosphate produced by one molecule of MgATP and one molecule of bicarbonate. At the next active site the carbamate is phosphorylated by a second molecule of MgATP to give the final product. The generation of these highly reactive intermediates (ammonia, carboxyphosphate, and carbamate) has necessitated that the enzyme develop a way to channel them through its interior, thus keeping them away from bulk solvent where they would rapidly decompose. The enzyme is under the allosteric control of various effector molecules including potassium, ornithine, and UMP. Under most conditions CPS is active as an $\alpha_4\beta_4$-heterotetrameric species. Despite the large size of the tetrameric enzyme (640K) the crystals diffract to at least 2 Å with synchrotron radiation, allowing for detailed structural analyses of the interactions between these effector molecules and the enzyme.

P11.04.024 δ CRYSTALLIN: A MODEL FOR STUDYING THE ENZYMATIC MECHANISM OF ARGININOSUCCINATE LYASE. Liliana M. Sampaleanu, Francois Vallée, Anita Chakraborty and P. Lynne Howell. Structural Biology and Biochemistry, The Hospital for Sick Children, Toronto, Ontario, and Dept. of Biochemistry, University of Toronto, Toronto, Ontario, Canada

Structural and functional analysis of wild type, chimera and site-directed mutants of duck δ-1 and δ-2 crystallin have been used to probe the enzymatic mechanism of argininosuccinate lyase (ASL), the urea cycle enzyme that catalyses the reversible breakdown of argininosuccinate to arginine and fumarate. The major soluble component of avian eye lenses, δ-crystallin, is directly related to ASL. In duck lenses there are two δ crystallin isoforms, δ-1 and δ-2. The two proteins are 94% identical in amino acid sequence and while δ-2 is the duck orthologue of ASL, δ-1 is enzymatically inactive. Domain swapping experiments have been used to assess the role of each structural domain of the δ-crystallin monomer. The kinetic and thermodynamic analysis of the chimeras revealed that only the N-terminal domain is crucial for recovery of ASL activity in δ-1 crystallin. The residues implicated in the catalytic mechanism of δ-2/ASL are conserved in δ-1. This suggests that the lack of catalytic activity in δ-1 crystallin is due to the conformational changes observed in the structural comparisons of δ-2 crystallin mutants (H91N and H162N with bound substrate) and turkey δ-1 crystallin. These structural studies have also revealed which residues interact with the substrate and that a conformational change occurs in the N-terminal domain on substrate binding. Site directed mutagenesis studies of δ-2 crystallin have confirmed the importance of a number of residues in substrate binding and catalysis. Our current understanding of the structure and function of ASL/δ-crystallin will be presented.

Funded by a grant from the Medical Research Council of Canada.

P11.04.025 STRUCTURE OF T AND R CONFORMERS FROM A MUTANT (K160E) OF GLCN6P DEAMINASE WITH MICHAELIS-TYPE KINETICS., E. Rudiño-Piñera and E. Horjales, Molecular Recognition and Biostructure Department, Biotechnology Institute, National Autonomous University of Mexico (UNAM), Av. Universidad No. 2001, Col. Chamilpa, CP. 62210, Cuernavaca, Morelos, MEXICO. E-mail: rudino@ibt.unam.mx

The glucosamine 6-phosphate deaminase (GlcN6P deaminase) is an allosteric enzyme which catalyses the reversible reaction between glucosamine 6-phosphate and fructose 6-phosphate and ammonium. In the allosteric site of the protein (which is activated with N-acetyl-glucosamine-6-phosphate (NAG6P)) the residue K160 is part of the interactions that bind the NAG6P, the mutation K160E changes the electrostatic balance in the allosteric site and produce a michaellian kinetics (1). In the present work we solved the x-ray crystallographic structure of the T conformer of GlcN6P deaminase K160E at 2.1Å giving a final R=0.219 (Rfree=0.233). The R conformer ligated with the competitive inhibitor 2 desoxy-2-amino-D-glucitol-6-phosphate was crystallised. The present state of the refinement shows an R=0.269 (Rfree=0.325) at 2.3 Å resolution. The conformations are the same as in the native forms, but exist differences in the temperature factors (B) distribution of the active site lid (residues 158-185).

The explanation of the crystallographic facts in relation with the kinetical studies is still in progress.

Acknowledgements: We wish to thank Dr. Mario Calcagno and Samuel Lara for supplying the purified mutant protein and for helpful discussions, Sonia Rojas-Trejo for technical assistance, the SSRL for data collection time. This study has been supported by DGAPA-UNAM (Grant IN-201295). E. Rudiño-Piñera is supported by CONACyT .

P11.04.026 X-RAY STRUCTURE OF MN^{2+}-BOUND PHOSPHOENOLPYRUVATE CARBOXYLASE FROM *E. COLI*. Y. Kai[1], H. Matsumura[1], M. Terada[1], S. Shirakata[1], T. Inoue[1], T. Yoshinaga[2], and K. Izui[3], [1]Department of Materials Chemistry, Graduate School of Engineering, Osaka University, Suita, Osaka, 565-0871, [2]Department of Public Health, Graduate School of Medicine, and [3]Division of Applied Biosciences, Graduate School of Agriculture, Kyoto University, Sakyo-ku, Kyoto, 606-8501, Japan.

Phosphoenolpyruvate carboxylase (EC 4.1.1.31) catalyses the irreversible carboxylation of PEP to form oxaloacetate and inorganic phosphate. A divalent metal ion such as Mn^{2+} or Mg^{2+} is required for activity of the enzyme. The enzyme is widespread in higher plants, algae and many kinds of bacteria, and plays an anaplerotic role by replenishing C_4-dicarboxylic acid to the tricarboxylic acid cycle. PEP carboxylase from *E. coli* is an allosteric enzyme which is activated by CoASc or fructose 1,6-bisphosphate and inhibited by L-aspartate. Although we have determined the crystal structure of *E. coli* PEP carboxylase complexed with L-aspartate, the reaction mechanism for PEP carboxylase was not determined clearly, because neither substrate analogue or metal is bound to the enzyme. At present we are trying to crystallize *E. coli* PEP carboxylase complexed with substrate analogue and metal. The previous studies suggested that Mn^{2+} or Mg^{2+} can bind to the active site of PEP carboxylase even in the absence of PEP. It is improtant to determine the metal binding site in the enzyme, which would provide the molecular mechanism for catalysis. We crystallized Mn^{2+}-bound PEP carboxylase from *E. coli* and determined the location of Mn^{2+} binding to the active site. The structure of the Mn^{2+}-bound enzyme was refined to a crystallographic *R* factor of 22% (R_{free} = 26%) at 2.6 ≈ resolution. These results will provide insight into the mechanism of substrate binding.

P11.04.027 MOUSE ORNITHINE DC: SUICIDE INHIBITOR COMPLEX WITH DFMO AND STEREOCHEMCIAL IMPLICATIONS. Marvin L. Hackert, Andrew Kern, Marcos Oliveira, Jeff Almrud, Don Carroll, Steve Ernst and Phil Coffino[1], Dept. of Chemistry and Biochemistry, Univ. of Texas at Austin, Austin, TX 78712, and [1]Dept. of Microbiology and Medicine, UCSF, San Francisco, CA 94143.

Ornithine decarboxylases (ODCs) are PLP-dependent enzymes which initiate the first and rate-limiting step in the biosynthesis of polyamines. Polyamine metabolism is a target for the design of new anticancer and antiparasitical compounds. Sequence comparisons reveal four Groups of PLP-dependent decarboxylases, but there appear to be only two structural motifs. Decarboxylases of Groups I, II, and III possess a PLP-binding domain that resembles that found in the AAT's as seen in the structure of the bacterial ODC from *Lactobacillus* 30a. The eukaryotic ODCs belong to the Group IV decarboxylases which also includes biosynthetic ArgDC and diaminopimelate DC.

The crystal structure of mouse ODC (mODC') has been determined to 1.6Å resolution by multiple isomorphous replacement and the structure of a suicide inhibitor complex with DFMO is being refined to 2.5Å resolution. ODC is active as a 100Kda dimer formed through a head-to-tail interaction between monomers. Each monomer contains two domains: an α/β-barrel domain which binds the cofactor, and a second domain consisting mostly of β-structure. Only the dimer is catalytically active, since its two active sites are constructed of residues from both monomers. The suicide inhibitor DFMO is found covalently linked to K69 but not C360 as expected. The analysis of the mODC'/DFMO complex, together with modelling studies of the external aldimine intermediate, provide insight into the stereochemical characteristics of PLP-dependent decarboxylation and reveals unexpected stereochemical differences with other PLP-dependent enzymes and with the bacterial ODCs.

Supported in part by grants NIHGM 30105 and the Foundation for Research.

P11.04.028 CRYSTALLIZATION AND PRELIMINARY X-RAY STRUCTURE ANALYSIS OF A CISTEINE PROTEASE FROM THE PILEUS MEXICANUS LATEX: MEXICAIN. Ma. Carmen Oliver-Salvador [1], Abel Moreno-Carcamo [2], Richard Laursen, Zhirui Lian [3], Manuel Soriano-Garcia [2], [1] Unidad Profesional Interdisciplinaria de Biotecnologia, IPN and Departamento de Bioestructura, Instituto de Quimica, UNAM, [2] Departamento de Bioestructura, Instituto de Quimica, UNAM, [3] Department of Chemistry, Boston University, Boston, MA, USA

The cysteine proteases from plants (Caricaceaes and Bromelaceas) are a group of enzymes used industrially, and their application in food and beer industry has a great commercial value (25% of enzyme trade). In addition, these enzymes are used for pharmaceutical purposes. The archetypal papain from Carica papaya latex has considerable uses such as: beer and tanning industries, meat tenderization, etc. Mexicain is also a cysteine peptidase, isolated from Pileus mexicanus (Caricaceae). The mexicain, is one of the most abundant enzyme in the latex. This plant is related to papaya (C. papaya). Mexicain hydrolyze casein with or without cysteine. Besides benzoyl-L-arginine ethyl ester (BAEE) & N-Benzoyl-DL-arginine -4-nitroanilide (BAPNA). Mexicain has 214 amino acid residues (Mr=23,718 Da) and possesses 62.8% (identity) in amino acid sequence with chymopapain (IYAL) and 81.3 % (homology). Mexicain PIv E-64 has been crystallized at 18C by the hanging-drop vapor diffusion method. The reservoir solution contained 10% (w/v) PEG 6000, 0.1M citric acid pH 4.0. Equal volumes of the reservoir solution and 10 mg/ml protein solution in distillated water were mixed to give 6 ml drops. Small rod- shaped crystals were grew within three months. The crystals are orthorhombic and diffract X-ray up

to 2.8 resolution. The optimization of the crystal size and the data collection method using synchrotron radiation is under way.

Ma. Carmen Oliver-Salvador thanks COFFA-IPN

P11.04.029 STRUCTURAL BASIS FOR STEREOSPECIFIC OXIDOREDUCTION: CRYSTAL STRUCTURES OF TWO TROPINONE REDUCTASES. A. Yamashita,[1,4] K. Nakajima,[2] H. Kato,[1] H. Akama,[2] T. Nakatsu,[1] S. Wakatsuki,[3] T. Tomizaki,[3] T. Hashimoto,[2] Y. Yamada,[2] and J. Oda[1,5], [1]Institute for Chemical Research, Kyoto University, Uji, Kyoto 611-0011, Japan, [2]Graduate School of Biological Sciences, Nara Institute of Science and Technology, 8916-5, Takayama, Ikoma, Nara 630-0101, Japan, [3]ESRF, BP-220, Grenoble, Cedex 09, France, [4]RIKEN Harima Institute, 323-3, Mihara, Mikazuki, Hyogo 679-5143, Japan, [5]Fukui Prefectural University, 4-1-1 Kenjojima, Matsuoka, Fukui 910-1195, Japan.

A pair of tropinone reductases (TR) has the opposite stereospecificity on the 3-carbonyl group reduction of tropinone: TR-I forms tropine with the 3α- hydroxyl group, while TR-II forms pseudotropine with the 3β- hydroxyl group. In spite of this different specificity for tropinone reduction, two enzymes have same stereospecificity for NADPH and share 64 % identical residues in their amino acid sequences. We report here the crystal structure of both TR-I and TR-II, and the structural basis of their enzymatic catalysis, especially how these enzymes control their strict stereospecificities.

The crystal structures of both TRs have been determined independently at 2.4 Å (for TR-I) and 2.3 Å (for TR-II) resolution using MIR [1]. The overall structures of the two enzymes were strikingly similar. Further determination of the crystal structure of TR-II complexed with $NADP^+$ and pseudotropine at 1.9 Å resolution revealed the detailed structure of the active site. The NADP(H) binding mode and the positions of catalytic residues were similar between TR-I and TR-II. The substrate binding site of TR-II showed the good complementarity to the bound substrate (pseudotropine). In addition, electrostatic interaction between the substrate and the binding site seems to fix the binding position and orientation of the substrate. On the other hand, the corresponding area in TR-I which is presumed to be the binding site provides different van der Waals surfaces and electrostatic natures from that in TR-II. These differences likely contribute to differentiating the substrate binding mode of TR-I from that of TR-II; TR-I binds the substrate in " upside-down" orientation compared to TR-II. These results suggest that the active site structures of the both enzymes control their substrate binding modes and determine their reaction stereospecificities.

P11.04.030 ALLOSTERIC REGULATION OF 5-PHOSPHORIBOSYL-1-PYROPHOSPHATE SYNTHASE. Frank Nygaard and Sine Larsen. Centre for Crystallographic Studies, Universitetsparken 5, University of Copenhagen, DK-2100 Copenhagen, DENMARK

PRPP synthase (PRS) which synthesizes 5-phosphoribysyl-1-pyrophosphate (PRPP), is one of the important enzymes in the pyrimidine and purine *de novo* biosynthesis and salvage pathway. It is a highly regulated enzyme justified by its position between several biological pathways. Inorganic phosphate and ADP serve as allosteric activator and inhibitor respectively. The three-dimensional structure of PRS from *Bacillus subtilis* (*b.s.*), which share ~50% sequence identity with the human PRS, has recently been determined in complexes with the allosteric inhibitor, ADP, and the activator, SO_4^{2-} (mimicking a PO_4^{2-} ion) (1). A sequence alignment of the more than 40 known PRS sequences, together with the *b.s.* structure, shows that many residues which are important for catalysis and its regulation are conserved.

Infantile or childhood onset of hyperuricemia and gout accompanied by neurodevelopmental disorders in humans has been ascribed to mutations in the *prs* gene causing a superactive PRS with decreased phosphate requirement and increased ADP inhibitor-resistance. Six such mutants, of which all are point mutations, have to date been identified (2). In order to further investigate the allosteric regulation of the PRS, six *b.s.* mutants containing the equivalent human mutations causing superactive PRS'es have been constructed. These mutants are being used for both structural as well as kinetic studies of the allosteric regulation of the PRPP synthase.

P11.04.031 THE CRYSTAL STRUCTURES OF THE COMPLEXES BETWEEN BOVINE BETA-TRYPSIN AND TEN P1 VARIANTS OF BPTI. A.O. Smalås, R. Helland and O. Sundheim [1], J. Otlewski [2], M. Dadlez [3]. [1] Department of Chemistry, University of Tromsø, 9037 Tromsø, Norway. [2] Institute of Biochemistry and Molecular Biology, University of Wroclaw,Tamka 2, 50-137 Wroclaw, Poland. [3] Institute of Biochemistry and Biophysics, Polish Academy of Sciences, Pawinskiego 5a, Warsaw, Poland.

The X-ray structures have been determined for ten complexes formed between bovine beta-trypsin and P1 variants (Gly, Asp, Glu, Gln, Thr, Met, Lys, His, Phe, Trp) of bovine pancreatic trypsin inhibitor (BPTI). All complexes were crystallised from the same conditions. The structures of the P1 variants Asp, Glu, Gln and Thr, are reported here for the first time in complex with any serine proteinase. The resolution of the structures ranged from 1.75 to 2.05 Å and the R-factors were about 19-20 %. The association constants of the mutants ranged from 1.5x104 to 1.7x1013 M-1. All structures could be fitted into well defined electron density, and had very similar global conformations. All P1 mutant side chains could be accomodated at the primary binding site, but relative to the P1 Lys, with small local changes within P1-S1 interaction site. These comprised: (1) changes in the number and dynamics of water molecules inside the pocket, (2) multiple conformations and non-optimal dihedral angles for some of the P1 side chains, Ser190 and Gln192, and (3) changes in temperature factors of the pocket walls as well as the introduced P1 side chain. Binding of the cognate P1 Lys is characterised by almost optimal dihedral angles, hydrogen bonding distances and angles, in addition to considerably lower temperature factors. Thus, the trypsin S1 pocket seems to be designed particularly for lysine binding.

P11.04.032 STRUCTURE OF HUMAN MITOCHONDRIAL ALDEHYDE DEHYDROGENASE AT 1.9Å. Monica. Niederhut and Thomas D. Hurley. Department of Biochemistry and Molecular Biology. Indiana University School of Medicine, Indianapolis, IN 46202

The mitochondrial form of aldehyde dehydrogenase is encoded by the ALDH2 gene and is one of nine known human genes for aldehyde dehydrogenase. The mitochondrial form is a tetramer of identical 55 kD subunits and is known to be the primary enzyme responsible for the oxidation of acetaldehyde to acetate during ethanol metabolism. We previously reported the structure of the ALDH2 isoenzyme from beef liver at 2.65Å which shares 95% sequence identity with the human enzyme. Here we report the crystallization and structure determination of the recombinant human ALDH2 enzyme expressed and purified from *E. coli*. The data could be indexed in the space group $P2_1$ with the

following cell dimensions a=101.4Å, b=176.1Å, c=101.5Å, β=95.0º. The crystals exhibit diffraction to >1.8Å and a 97% complete data set to 1.92Å was collected at the X12C beam line at the National Synchrotron Light Source. The model was initially refined using X-PLOR 3.8 and is now being refined with REFMAC. Currently the model contains residues 7-500 in each subunit, a bound cofactor molecule with an associated Mn^{2+} ion in each subunit, and a total of 1700 water molecules in both tetramers within the asymmetric unit. At this point in the refinement the R-free value is 28.5% and the R-work is 22.6% for all data between 35 and 1.92Å, using a bulk solvent correction. NCS-restraints have been imposed to this point in the refinement. However, clear differences can be seen in the structure and future rounds of refinement will not utilize ncs-restraints. The electron density for the bound cofactor also appears to vary in its overall intensity when compared between subunits. These subtle differences in subunit structure may be related to the enzyme's ½ sites reactivity, in which only two of the four identical active sites in the enzyme appear to function at any given instant. Supported by AA11982.

P11.04.033 CRYSTALLOGRAPHIC STRUCTURE OF THYMIDYLATE SYNTHASE FROM BACILLUS SUBTILIS. Kristin M. Fox, Department of Chemistry, Union College, Schenectady, NY 12308, Frank Maley, and Patrick Van Roey, Division of Molecular Medicine, Wadsworth Center, New York State Department of Health, PO Box 509, Albany, NY 12201-0509, USA

Thymidylate synthase (TS) converts dUMP to dTMP by transferring a methyl group from 5,10-methylene tetrahydrofolate to dUMP. This reaction is crucial for DNA synthesis, as it is the sole *de novo* source of dTMP. In addition, the uniqueness of the reductive methylation reaction has lead to study of the reaction mechanism by many different methods. Clarification of this mechanism has been provided by the determination of the structures of TS from several organisms, especially that from *Escherichia coli*. *B. subtilis* contains two genes for TS, ThyA and ThyB. The sequence of the *B. subtilis* ThyA enzyme is quite different from other TS's, and has a 2.5 fold greater k_{cat} than *E. coli* TS. Sequence analysis of residues in the active site area of *E. coli* TS showed that a histidine implicated in the hydrogen bonding network important for catalytic activity is replaced by valine in *B. subtilis* TS. The structure of the ThyA *B. subtilis* TS in a ternary complex with 5-fluoro-dUMP and 5,10-methylene tetrahydrofolate has been determined to 2.5 Å resolution. Overall, the structure is similar to that of the *E. coli* enzyme. However, there are significant differences in the structures of two loops, the dimer interface and the details of the active site. The effects of the histidine to valine substitution, but also of a serine to glutamine substitution, and the addition of a loop over the active site area may account for the differences in k_{cat} found between the two enzymes.

P11.04.034 STRUCTURE OF APS KINASE: AN ENZYME INVOLVED IN SULFUR ASSIMILATION. Ian J. MacRae[1], Irwin H. Segel[1], and Andrew J. Fisher[1,2]. [1]Section of Molecular and Cellular Biology and [2]Department of Chemistry, University of California, Davis CA 95616

Sulfur is the sixth most abundant element found in biological molecules. However, the most prevalent form of inorganic sulfur found under our oxygen atmosphere is the unreactive form sulfate (SO_4^{2-}). This fully oxidized form of sulfur is far too stable to be used directly as a substrate for incorporation into biological molecules under normal cellular conditions. To circumvent this problem, and use sulfate as a sulfur source, assimilatory organisms have evolved an enzymatic sulfate activation pathway. The first step in this sulfate fixation process is catalyzed by ATP sulfurylase which transfers the adenylyl group of ATP onto sulfate to produce adenosine-5'-phosphosulfate (APS). APS is then phosphorylated by the enzyme APS kinase to form 3'-phospho-adenosine-5'-phosphosulfate (PAPS). PAPS, the product of APS kinase, is used as "activated sulfate" in cells. It can serve as a substrate for making sulfate esters or be reduced to sulfite which is ultimately used in cysteine biosynthesis.

A cDNA clone of APS kinase from the assimilatory fungus *Penicillium chrysogenum* has been expressed in *E. coli*. The soluble enzyme was purified to homogeneity and crystallized in the orthorhombic space group $C222_1$ with unit cell parameters of a =79.4 A, b = 83.9 A, and c = 142.4 ⊕. Initial phases were calculated from two derivatives using MIR methods. The APS kinase structure is currently in the final stages of refinement at 1.9 Å resolution. Consistent with previous biochemical studies (J. Biol. Chem. **260**: 1535 - 1544, 1985), the enzyme crystallized as a homodimer. Each subunit is composed of a parallel β sheet sandwiched between two α-helical bundles. The Walker A motif (residues 32-39, GLSAGKS in this enzyme) forms a typical ATP - binding P-loop. Serine-107, shown not to be a phosphoryl acceptor, but suggested to reside in the substrate binding pocket (J. Biol. Chem. **273:** 28583 - 28589, 1998), lies adjacent to the P-loop. These features point to the vicinity of the active site. The overall conformation establishes APS kinase as a member of the super family of mononucleotide binding proteins with particular structural homology to adenylate kinase, 6-phosphofructo-2-kinase, and the catalytic core of p21-Ras.

P11.04.035 STRUCTURE OF THE HUMAN N^5,N^{10}-METHYLENTETRAHYDRO-FOLATE DEHYDROGEN-ASE/ CYCLOHYDROLASE BOUND TO THE INHIBITOR N^5,N^{10}-CARBONYL-TETRAHYDRO-FOLATE. Andrea Schmidt, Yunge Li, Marc Allaire and Miroslaw Cygler, Biotechnology Research Institute, NRC, Canada; Robert E. MacKenzie, Dept. Biochem., McGill University, Montreal, Canada.

The enzyme N^5,N^{10}-methylen[H4]folate dehydrogenase/ cyclohydrolase DC301 consists of two domains, catalyzing sequential reactions with a shared substrate binding site. The dehydrogenase reaction is NADP dependent, and the cofactor was present in the native structure [Allaire *et al. Structure* 6, 173 (1998)]. We have now determined the structure of the enzyme cocrystallized with the substrate-like inhibitor N^5,N^{10}-carbonyl-[H4]folate in the presence of NADP. DC301 forms dimers in solution and the crystal contains one dimer per asymmetric unit, the two molecules differing in the hinge angle between the two domains. The inhibitor was found only bound to molecule A, which has a narrower substrate binding cleft. The position and orientation of the inhibitor molecule is well defined although the glutamate sidechain and the outermost part of the pteridine ring are rather poorly defined in the electron density map. The inhibitor interacts with the protein via H-bonds to Asp125, Lys56 and the backbone O and NH of amino acids 101, 273 and 276, and stacking interaction with Tyr52. NADP is located opposite to the tyrosine, with its nicotine ring located beneath the imidazone ring of the inhibitor. Tyr52 and Lys56 are part of the Tyr-X_3-Lys motif encountered in the SCAD protein family and had been proposed to take part in the cyclohydrolase step. Lys56 is in a position to interact with both the carbonyl group of the imidazone and the hydroxy group in position 4, possibly also N5, and therefore appears to play an essential role in binding and catalysis. The observed location of Tyr56 positions its OH group too far from the substrate's reactive part. Therefore, this sidechain may be important for the proper positioning of the substrate, but likely plays no direct role in the enzymatic reaction. This is consistent with mutagenesis studies.

We would like to thank Drs. J. Toth, V. Chen, Mr. J. Ray and Eli Lilly and Company for providing the inhibitor and for financial support.

P11.04.036 CRYSTAL STRUCTURE ANALYSIS OF FERREDOXIN AND FERREDOXIN-NADP$^+$ REDUCTASE FROM MAIZE ROOT. G.Kurisu, R.Igarashi, S.Suzuki, M.Kusunoki and T.Hase, Institute for Protein Research, Osaka University, Suita, Osaka 565-0871, Japan.

In the electron transfer system of photosynthesis, Ferredoxin (Fd) works as an electron carrier to Ferredoxin-NADP$^+$ reductase (FNR). Specifically Fd is reduced by Photosystem I (PSI) in the chloroplast. Then FNR receives the electron from the reduced Fd. Finally it catalyzes the reduction of NADP$^+$ to NADPH. Recently it was found that the non-photosynthetic tissues such as fruits or roots have Fd and FNR isomers distinct from photosynthetic ones. These second types of Fd and FNR are involved in an electron transfer process to some Fd-dependent enzymes from NADPH supplied via the oxidative pentose phosphate cycle. In order to understand this electron transfer pathway and how it differs from a photosynthetic one, we started the crystallographic analysis of the isomers.

Non-photosynthetic Fd and FNR from maize root were expressed in *E.coli*. and purified to sufficient quality for crystallization. Crystals of Fd were prepared using the ammonium sulfate as a precipitant ($P2_12_12_1$, a=79.8, b=104.51, c=66.43 Å). A crystal structure of the Fd was solved at 2.5 Å resolution by MR method. Main chain structures are quite similar to those of other plant type Fds. On the other hand, crystals of FNR were obtained using the sodium citrate ($P3_121$, a=59.44, b=59.55, c=187.09 Å). We have collected the X-ray diffraction data up to 1.65 Å resolution from one crystal at the Photon Factory. The molecular structure was solved by MR method using AMORE. Refinement of this structure is in progress.

P11.04.037 CRYSTAL STRUCTURE OF MAMMALIAN PURPLE ACID PHOSPHATASE TO 1.55 Å RESOLUTION. L.W. Guddat[1], A. S. McAlpine[1], D. Hume[1], S. Hamilton[1], J. De Jersey[1], J. L. Martin[2]. Department of Biochemistry[1] and Centre for Drug Design and Development[2], The University of Queensland, St. Lucia, Qld, Australia 4072.

Purple acid phosphatases are a group of non-specific phosphomonoesterases that are widespread in nature. Mammalian purple acid phosphatases were first identified in pig uterine secretions and in bovine spleen. High concentrations of the enzyme have also been found in osteoclasts and macrophages. The physiological role and enzymatic specificity of the protein are unknown. Its abundance in pig allantoic fluid, suggests a role in iron transport between the mother and fetus. Experiments with transgenic mice indicate that purple acid phosphatases play an important role in bone homeostasis[1]. Purple acid phosphatases are characterised by a redox active, binuclear metal centre. In mammals, the metal centre is spin coupled Fe(III)-Fe(II). The distinctive purple colour results from a charge transfer transition between a tyrosinate and the Fe(III) at 560nm.

To date the only reported structure of a purple acid phosphatase is that of the red kidney bean enzyme[2,3]. Despite very low sequence homology, a tentative model for the structure of mammalian purple acid phosphatase has been proposed based on a sequence alignment and secondary structure prediction[4]. Here, we report the high resolution structure (1.55 Å) of the phosphate-bound enzyme, purified from pig allantoic fluid. The structure was solved using the MIR method. For the first time, the critical hydroxo bridge is shown providing additional insight into the catalytic mechanism and active site structure of this class of enzyme. Comparison of the structures of the mammalian and plant purple acid phosphatases show that their binuclear metal sites are almost identical but significant differences nearby may be important for substrate specificity. Internal two-fold pseudo symmetry suggests that the binuclear metal ion centre may have evolved from a combination of mononuclear domains. The structural elucidation of the mammalian enzyme is a significant step towards rational drug design that could lead to treatments for bone diseases.

P11.04.038 MOLECULAR MECHANISM OF SUBSTRATE ANALOG RECOGNITION BY FLAVIN REDUCTASE, FRase I, FROM BIOLUMINESCENT BACTERIUM. Masaru Tanokura, Toshiro Kobori, Departments of Applied Biological Chemistry and Biotechnology, Graduate School of Agricultural and Life Sciences, University of Tokyo, Tokyo 113-8657, Japan, Hideaki Koike, Hiroshi Sasaki, Biotechnology Research Centre, University of Tokyo, Tokyo 113-8657, Japan, and Shuhei Zenno, Kaoru Saigo, Department of Biophysics and Biochemistry, Graduate School of Science, University of Tokyo, Tokyo 113-0033, Japan.

FRase I from the bioluminescent bacterium *Photobacterium* (*Vibrio*) *fischeri* is a flavin reductase and is considered to play an essential role to the luminescence by supplying the reduced form of flavin mononucleotide ($FMNH_2$) to luciferase. The crystallographic and biochemical studies have indicated that the enzyme acts as a homodimer in solutions and holds tightly one FMN molecule per subunit. We report the crystal structures of the complexes of the enzyme with coumarin derivatives to elucidate the molecular mechanism of substrate recognition by the enzyme.

Based on the enzyme kinetics, coumarin derivatives, including *o*-coumaric acid, 4-hydroxycoumarin, warfarin, and dicoumarol, were indicated to act as competitive inhibitors, while coumarin itself did not inhibit the enzyme at all. Thus the coumarin derivatives occupy the same binding site of the enzyme as substrates. The crystals of FRaseI-inhibitor complexes were obtained by soaking inhibitors to FRaseI crystals. The crystals diffracted X-rays to around 2.0 Å resolution, by using the Weissenberg camera for macromolecular crystallography with a synchrotron radiation in Tsukuba, Japan. In the crystal structures of the enzyme-inhibitor complexes, coumarin derivatives were sandwiched with the FMN cofactor and side chain of phenylalanine-124 at an active site of the enzyme. In addition, each of the inhibitors hydrogen-bonded to the main chain amide nitrogen of isoleucine-43 of the other subunit at its hydroxyl group. Comparison of the structure with that of FRP, another flavin reductase, has shown that phenylalanine-124 is important for the recognition of the inhibitors by FRase I.

P11.04.039 THE CRYSTAL STRUCTURE OF GABA-AMINOTRANSFERASE, A TARGET FOR ANTIEPILEPTIC DRUG THERAPY. Storici, P., Capitani, G.,. De Biase, R.A. John, J.N. Jansonius and T. Schirmer, Division of Structural Biology , Biozentrum, University of Basel, CH-4056 Basel, Switzerland; Deptartment of Biochemical Sciences, University La Sapienza, I-00185 Rome, Italy; School of Molecular and Medical Biosciences, University of Wales, CF1 3US Cardiff, UK.

γ-aminobutyrate aminotransferase (GABA-AT; EC 2.6.1.19) is a pyridoxal 5'-phosphate (PLP) dependent enzyme which belongs to the subgroup of aminotransferases acting on ω-amino acids, i.e. amino acids containing the removable amino

group in a position distal to the carboxyl group. This α_2-dimeric enzyme is involved in the breakdown of the inhibitory neurotransmitter GABA in that it converts, by a ping pong bi bi type reaction mechanism, GABA and 2-oxoglutarate into succinic semialdehyde and L-glutamate, respectively.

GABA-AT is presently regarded as one of the most interesting targets for antiepileptic drugs because its selective inhibition raises GABA concentrations in the brain.

The crystal structure of pig liver GABA-AT was solved by molecular replacement using the model of human ornithine aminotransferase (OAT) with which it shares 23% sequence identity. Due to the low similarity with the search model and the presence of two dimers per asymmetric unit, the cross-rotation function was not readily interpretable. The problem was solved by using the resulting list of 50 rigid body-fitted solutions for an exhaustive two-dimer search. Subsequent four-fold molecular averaging and phase extension to 3 Å yielded well-defined unbiased electron density. The success of this approach is remarkable, since the dimeric search model comprised only 24 % of the atoms of the two dimers contained in the asymmetric unit. Structural superposition of the final refined GABA-AT monomer with OAT shows a relatively large r.m.s. deviation of 2.1 Å for 390 Cα positions.

GABA-AT has the same fold as OAT, with some local differences which can explain the origin of the different substrate specificities. The antiepileptic drug vinyl-GABA is modeled into the active site and an explanation is offered for the efficacy of this mechanism-based inactivator.

P11.04.040 PRELIMINARY CRYSTALLOGRAPHIC STUDIES OF A PHOSPHOENOLPYRUVATE (PEP) SYNTHETASE FROM *PRYOCOCCUS FURIOSUS*. Zhi-Jie Liu[1], Andrea M. Hutchins[1], M. Gary Newton[2], John P. Rose[1], Michael W. Adams[1], Bi-Cheng Wang[1]; [1]Department of Biochemistry & Molecular Biology, University of Georgia, Athens, GA 30602, USA; [2] Department of Chemistry, University of Georgia, Athens, GA 30602, USA

Phosphoenolpyruvate (PEP) synthetase catalyses the ATP-dependent conversion of pyruvate to phosphoenolpyruvate. The 98 kDa PEP synthetase from *Pyrococcus furiosus* has been isolated, purified to homogeneity and crystallized. The crystals were obtained by hanging-drop vapor-diffusion. Preliminary X-ray diffraction analysis indicates that the crystals belong to tetragonal space group $P4_12_12$ or $P4_32_12$ with unit-cell dimensions of a = b = 100.76 Å, c = 220.23 Å. The presence of one PEP synthetase molecule in the asymmetric unit gives a Matthews coefficient (Vm) of 2.85 $Å^3$ Da^{-1} and a calculated solvent content of 57% by volume. Native data to 2.0 Å has been collected at beamline ID-17 (IMCA-CAT) Advanced Photon Source, Argonne National Laboratory. The search for heavy atom derivatives is in progress.

P11.04.041 STRUCTURE AND CATALYTIC MECHANISM OF THE RHODANESE FROM *Azotobacter vinelandii*. D.Bordo, D.Deriu, and M.Bolognesi, Advanced Biotechnology Center ñ IST and Department of Physics-INFM, University of Genova, Italy.

Rhodanese is a thiosulfate:cyanide sulfurtransferase enzyme which is widely distributed among the mayor phyla. The best known catalyzed reaction is the transfer of a sulfane sulfur from thiosulfate to cyanide. The protein has been identified, cloned, overexpressed, purified and crystallized with the method of the hanging drop. Crystals belonging to the orthorombic space group $P2_12_12$ were obtained after a period of several months using the hanging drop setup and in presence of magnesium sulfate as precipitant.

The multiple isomorphous replacement technique was successfully used to obtain initial phase information. Several techniques, including maximum likelihood, solvent flattening, and phase extension were applied to the initial phases, and the final 1.8A map resulted of excellent quality. Most part of the main and side chains could be located with automated procedures, and the protein model of the complete amino acid chain (271 amino acids) could be refined to an R value of 17.4% (free-R factor, 21.9%).

In spite of a folding similar to that of the bovine rhodanese, to which the primary sequence of A.vinelandii rhodanese is 28% identical, the residues surrounding the active site cysteine display remarkable differences. Studies on the catalytic mechanism indicate that Arg235 undergoes wide side chain rearrangements and play a relevant role in the interaction with the substrates.

P11.04.042 PYRUVATE FORMATE LYASE LARGE DOMAIN: THE SECOND MEMBER OF THE RIBONUCLEOTIDE REDUCTASE FAMILY. V.-M. Leppänen[αβ], M. Merckel[β], D.L. Ollis[βγ], K. Wong[δ], J. Kozarich[δ] and A. Goldman[βα] [α]Centre for Biotechnology, University of Turku and Åbo Akademi University, POB 123, Turku, Finland, [β]Department of Biochemistry, University of Turku, Finland, [γ]Research School of Chemistry, Australian National University, ACT, 2614, Australia, [δ]Merck Research Laboratories, POB 2000, Rahway, NJ, USA

Pyruvate formate lyase (EC 2.3.1.54; PFL) catalyzes a key step in anaerobic glycolysis in *E. coli* by converting pyruvate and CoA to formate and acetylCoA. The enzymatic reaction has been proposed to proceed by an unusual radical cleavage of pyruvate, involving an essential Cα-radical of Gly 734 and two cysteines, Cys418 and Cys419 that may form thiyl radicals required for catalysis (reviewed by Wong and Kozarich)[1].

We have solved the first structure of a proteolytic fragment (1-624) of this class of enzymes at 2.8 Å resolution. We see a novel right-hand like two-domain structure, and a β-finger inserted into a part-barrel structure that exposes both Cys418 and Cys419 in a turn between two strands. The PFL structure also localizes several residues near the active site cysteines that may play a role in defining the catalytic mechanism.

The structure reveals a striking structural homology to the aerobic ribonucleotide reductase (RNR Type I)[2] as the catalytic domain of PFL can be superimposed on the aerobic RNR R1 protein, including 8 of the 10 strands in the unusual RNR a/b barrel. The relationship is undetectable at the sequence level. There is now a clear but very distant evolutionary relationship between PFL and aerobic RNR. Given the limited sequence and striking mechanistic homology between anaerobic RNR and PFL, we propose that enzymes with relatively stable amino-acid free radicals have a common fold, including at least PFL, aerobic RNR and anaerobic RNR.

P11.04.043 CRYSTAL STRUCTURES OF PURINE NUCLEOSIDE PHOSPHORYLASES FROM MICRO-ORGANISMS Koellner, G., Tebbe, J., Saenger, W. Institut für Kristallographie, Takustr. 6, 14195 Berlin, Germany, Bzowska, A., Wielgus-Kutrowska, B., Shugar, D. Departrment of Biophysics, University of Warsaw, Zwirki i Wigury 93, 02-089 Warsaw, Poland, and Luic, M. Rudjer-Boskovic Institute Bijenicka 54 10000 Zagreb Croatia.

Crystal structures of the enyzme Purine Nucleoside Phosphorylase (PNP) from *E.coli* in complex with Formycin A and Formycin B and *Cellulomonas sp.* in complex with phosphate and 8-iodoguanine are presented.

PNP is an ubiquitous enzyme, which catalyzes the reversible phosphorolysis of naturally occuring purine nucleosides and many analogues. Considerable attention is currently devoted to development of potent specific inhibitors of phosphorylases from various sources, because of their potential pharmaco-logical applications (e.g. as immunosuppressive or antiparasitic agents).

PNP from *E.coli* belong to the second class of PNPs which are also called high-molecular-weight or adenosine phosphorylases and appear as hexamers. PNP from *cellulomoas sp*. are trimeric, which usually is typical for mammalian PNPs. Both enzymes have very little sequence idenity to each other and to mammalian PNPs, but all three PNPs (mammlian, *E.coli* and *cellulomonas sp*.) have structural homologies: the core of each monomer consists of a nine-stranded mixed β-sheet surrounded by α-helices.

P11.04.044 CRYSTAL STRUCTURE OF REPETITIVE B-DOMAIN OF THE COLLAGEN BINDING SURFACE PROTEIN OF *STAPH. AUREUS*. Champion CS Deivanayagam, Rebecca L. Rich, Sita Danthuluri, Rick T. Owens, Joseph M. Patti, Magnus Hook, Lawrence, J. DeLucas and Sthanam, V.L . Narayana. *Center for Macromolecular Crystallography, 286 BHSB, 1918 University Boulevard, University of Alabama at Birmingham, AL 35294-0005, USA and #Center for Extracellular Matrix Biology, Albert K.Alkek Institute of Biosciences and Technology, Texas A&M University, 2121 Holcombe Boulevard, Houston, TX 77030-3303, USA.

A 135kDa protein (*cna*) from the newman strain of *Staphylococcus aureus* has been identified as a collagen binding MSCRAMM (microbial surface components recognizing matrix molecules)[1]. Molecular characterization of the gene revealed the presence of a non-repetitive A-domain and a repetitive B-domain. For analyzing the structure function relationship of this collagen adhesin, we determined the crystal structure of CBD19, which represents the smallest sub-fragment of the A-domain with measurable collagen binding activity [2]. In this report we present our structural studies of B_1 and B_1B_2 fragments of ***cna***.

Crystals of B_1 and B_1B_2 were grown using hanging drop vapor diffusion method[3]. Crystal structure of B_1 was solved by MIR method and the crystal structure of B_1B_2 was determined by molecular replacement using B_1 as the initial model. The overall structure of B_1 has two immunogloblulin like domains placed side by side. B_1 exhibits a different fold, although the overall structure is similar to the IgSF structures. It also carries an ëLDVí motif on the C-D loop region, which is strikingly similar to that observed in I-CAM2 and V-CAM1 structures [4,5], and are known to bind integrins. Although the function for B-domains is not clear, these repeat domains could project the A-domain over the bacterial cell wall aiding the binding to collagen [6], and may also bind to integrins. The crystal structure of B_1B_2 exhibits interesting domain duplication and swapping features.

P11.04.045 A NEW STRUCTURE-BASED REACTION MECHANISM FOR UREASE: WHY UREA HYDROLYSIS COSTS TWO NICKELS. S. Benini and W. R. Rypniewski, EMBL c/o DESY Notkestraße 85 D-22603 Hamburg, K. S. Wilson, Dept. of Chemistry, York University Heslington YO1 5DD UK, S. Ciurli, Inst. of Agricultural Chemistry, Bologna University, Viale Berti Pichat 10 I-40127, S. Mangani Dept. of Chemistry Siena University, Pian dei Mantellini 44 I-53100.

Urease catalyses the hydrolysis of urea in plants, algae, fungi, bacteria, to yield ammonia and CO_2. Urease is involved in pathologies (including cancer) induced by gastroduodenal infections by *H. pylorii*. The search of urease inhibitors has so far relied upon extended screen tests, while a structure-based drug design approach would give more direct results. The elucidation of the structure of the active sites of enzymes and the reaction and inhibition mechanism are fundamental for this approach. The highly conserved amino acid sequences of all known ureases and the constant presence of two Ni ions and of their ligands in the active sites imply a common catalytic pathway. The structure of urease from *B. pasteurii* has been studied extensively. Good quality data have been collected for native (2.00 Å) and acetohydroxamic (1.55 Å), β-mercaptoethanol (1.65 Å), diamidophosphate (2.00 Å) and mercaptoethanolamine (1.90 Å) inhibited enzyme. The comparison between native and inhibited urease suggested a new reaction mechanism that overcomes the problems encountered by the mechanism proposed for *K. aerogenes* urease. The new reaction mechanism and an overview of all structures is presented.

P11.04.046 CRYSTALLOGRAPHIC STUDIES OF JACK BEAN UREASE IN COMPLEX WITH AN ANTIBODY FRAGMENT. L. Smith, C. M. Wilmot and S. E. V. Phillips, School of Biochemistry and Molecular Biology, University of Leeds, Leeds, LS2 9JT, UK, K. Cromie, and P. van der Logt, Biorecognitions unit, Unilever Research, Colworth House, Sharnbrook, Bedford, MK44 1LQ, UK.

Urease allows an organism to use external and internally generated urea as a nitrogen source. It catalyses the hydrolysis of urea to form ammonia and carbon dioxide. Urease probably participates also in the systematic nitrogen transport pathways and possibly acts as a toxic defence protein. Jack bean urease (JBU) was the first known nickel metalloenzyme(1) and was first crystallised in 1926, by J. B. Sumner.(2) It is a large protein, in solution it normally exists as trimers and hexamers of identical 96 kDa subunits.

Although there have been crystals for over 70 years, the structure has not yet been determined. The crystals diffract to a resolution of 3.5 Å,(3) and belong to the space group $F4_132$ with a = 364 Å. The large unit cell, high symmetry and relatively weak diffraction have made this structure sifficult to solve.

We have managed to produce an Fv, a 24 kDa antibody fragment, that has a high affinity to JBU, using a Pichia pastoris expression system, and purified using a his-tag. One Fv binds to

one monomer of JBU, forming a 120 kDa complex, although the complex can still form oligomers. Whilst in this complex, the urease activity is not affected.

We report here the structure of JBU in the space group R32, a = b =229.7 Å, c = 131.5 Å.

P11.04.047 STRUCTURAL STUDIES ON HUMAN AND BOVINE XANTHINE OXIDASE. A. Pearson, G. Taylor, School of Biomedical Sciences, The University of St. Andrews, UK, and R. Harrison, School of Biology and Biochemistry, The University of Bath, UK.

Xanthine oxidase (XO) is a dimeric (2 x 150 kDa) metalloprotein that catalyses the last step in purine catabolism. It is also able to act as an NADH oxidase and has been implicated in the production of reactive oxygen species in ischaemic injury [1]. Each monomer contains one molybdopterin, one FAD and two iron sulphur clusters [2]. We have so far obtained micro-needles and micro-plates of folate affinity-purified bovine milk XO and micro-needles of human milk XO. The difficulty encountered in obtaining diffraction quality crystals may be due to microheterogeneities in the 'pure' enzyme, as various inactive forms (lacking one or more co-factors) have been shown to exist [3]. We are currently investigating methods of further purifying XO by separating the various active and inactive forms.

To this end we are developing the use of SEM X-ray microanalysis and ICPS as tools for determining quantitatively the amounts of iron, molybdenum and phosphorous in XO preparations.

XO domain models have been constructed based on the aldehyde oxidoreductase structure (high sequence homology to the molybdopterin and FeS domains) [4] and the MurB (structural similarity to carbon monoxide dehydrogenase, a XO related enzyme [Dobbek, personal communication]) structure [5]. It is hoped these models will be useful as phasing models in molecular replacement.

We are also sequencing the human milk enzyme in order to investigate whether the XO activity in enzyme preparations from different sources (human milk-low, human liver-high, bovine milk-high) is sequence related.

P11.04.048 STRUCTURE OF DIOL DEHYDRATASE REVEALS A NEW B_{12}-BINDING MODE AND A ROLE OF ESSENTIAL POTASSIUM ION. N. Shibata and J. Masuda, Department of Life Science, Himeji Institute of Technology, 1475-2 Kanaji, Kamigori, Ako, Hyogo 678-1297, Japan, and T. Tobimatsu and T. Toraya, Department of Bioscience and Biotechnology, Faculty of Engineering, Okayama University, Tsushima-Naka, Okayama 700-6082, Japan, and K. Suto, Y. Morimoto and N. Yasuoka, Department of Life Science, Himeji Institute of Technology, 1475-2 Kanaji, Kamigori, Ako, Hyogo 678-1297, Japan.

We report on a crystal structure of a novel vitamin B_{12} enzyme and a B_{12}-dependant radical reaction mechanism. The structure reveals that an essential potassium ion deeply buried in protein interior participates in substrate-binding and the reaction. Diol dehydratase catalyzes the conversions of 1,2-diols to the corresponding deoxy aldehydes, which requires adenosylcobalamin and monovalent cation as a cofactor. Apoenzyme is composed of three polypeptide chains with molecular weights of 60k (α), 24k (β), and 19k (γ). Crystal structures of other B_{12}-enzymes reveal that a Co-dimethylbenzimidazole (Co-DBI) bond is broken and a histidine coordinates to Co instead of DBI. On the contrary, diol dehydratase has been reported that it conserves the intrinsic Co-DBI bond.

Crystals of diol dehydratase-cyanocobalamin complex were grown by vapor diffusion. Native data were collected at SPring-8 and the structure was determined by MIRAS. Diol dehydratase is dimer of $\alpha\beta\gamma$ unit and α subunit has the TIM barrel motif. Cyanocobalamin is located between a C-terminal face of the TIM barrel and β subunit. DBI was found in β subunit side and the enzyme keeps the Co-DBI bond. An active site is on the upper side of the cobalamin. A deep cavity found in the TIM barrel forms the active site. The K^+ ion is found at the center of the TIM barrel and it holds a 1,2-propanediol molecule. A C1 atom of the propanediol is about 8 Å above Co atom. An adenosyl group should occupy the cavity between the corrin ring and the propanediol molecule. An activation of Co-adenosyl bond yields an adenosyl radical, reacting with 1,2-diol compound. The K^+ ion may assist migration of hydroxyl group.

P11.04.049 STRUCTURES OF CUZN SUPEROXIDE DISMUTASE IN TWO CRYSTAL FORMS: SUGGESTIONS OF A FUNCTIONAL ASYMMETRY IN THIS ENZYME. M.A. Hough and S.S. Hasnain, CLRC Daresbury Laboratory, Warrington, Cheshire, WA4 4AD, UK.

Copper, zinc superoxide dismutase (CuZnSOD) scavenges the superoxide radical O_2^- to form O_2 and H_2O_2 and forms part of the defence mechanism of cells against free radical oxidative damage. The enzyme is present in all eukaryotic organisms and in some prokaryotes. The active site structure of the enzyme in the oxidised, Cu^{II}-SOD form has been well established by protein crystallography [1]. Two crystal structures of Cu^{I}-SOD have yielded conflicting results each of which support a different proposed enzymatic mechanism. We present a crystal structure of bovine CuZnSOD (BSOD) at 1.65Å resolution in which each subunit of the dimer adopts a different copper site coordination consistent with one subunit containing Cu^{II} and the other Cu^{I}. The structure provides clear support for a proposed enzymatic mechanism involving the protonation of the bridging His61 and it's dissociation from copper. A medium resolution crystal structure of Cu^{II}-BSOD in a different space group is also presented in which one subunit exhibits much higher temperature factors than the other. This behaviour is shown to be the result of differing crystalline environments for the two subunits. These structures provide some credence to the suggestion that there may be a functional asymmetry between the subunits of the dimer.

P11.04.050 CRYSTAL STRUCTURE OF Ni-Fe HYDROGENASE IN REDUCED FORM AT 1.4Å RESOLUTION. H. Ogata, K. Miki, Division of Chemistry, Graduate School of Science, Kyoto University, Sakyo-ku, Kyoto 606-8502 Japan, N. Yasuoka, Department of Life Science, Faculty of Science, Himeji Institute of Technology, Kamigori, Hyogo 678-1297 Japan, T. Yagi, Shizuoka University, Oya, Shizuoka 422-8529, Japan, Y. Higuchi, Division of Chemistry, Graduate School of Science, Kyoto University, Sakyo-ku, Kyoto 606-8502 Japan.

Hydrogenases are fundamental metalloenzymes for bacterial hydrogen metabolism. These enzymes are able to regulate the proton gradient between inside and outside of the

periplasmic membrane and to catalyze the reversible oxidoreduction of molecular hydrogen, in conjunction with a specific electron acceptor, cytochrome c_3. The active site of Ni-Fe hydrogenase in the oxidezed form is suggested to be a binuclear Ni-Fe complex having three non-protein diatomic ligands to the Fe atom and three bridging ligands between the Fe and Ni atoms. Here, we report the crystal structure of Ni-Fe hydrogenase in the reduced form of *Desulfovibrio vulgaris* Miyazaki F revealed by X-ray crystallography at 1.4 Å resolution. The folding pattern in the reduced form is very similar to that in the oxidized form. The electron density map shows that the monatomic bridging ligand reported as sulfur species at the Ni-Fe active site disappeared upon reduction with molecular hydrogen in the presence of its electron carrier. In addition, we found that the reduced enzyme released H_2S under the atmosphere of the hydrogen gas in the presence of electoron carriers. Therefore, we suggest that the monatomic sulfur bridge at the Ni-Fe site has to be removed for the enzyme to be activated.

P11.04.051 CRYSTALLOGRAPHIC AND ELECTRON DONATION STUDIES OF NITRITE REDUCTASE. Fraser E. Dodd, Loretta M. Murphy, S. Samar Hasnain [1], Robert R. Eady, Barry E. Smith [2], [1] CCLRC Daresbury Laboratory, Warrington, WA4 4AD, U.K., [2] Nitrogen Fixation Laboratory, John Innes Centre, Colney, Norwich, NR4 7UH, U.K.

Denitrification is one of the main steps of the global nitrogen cycle that is sustained by prokaryotic organisms [1]. Denitrifying bacteria use two entirely different enzymes in this process, one based on haem *cd1* prosthetic groups and the other on type 1 - type 2 Cu centres. Copper containing nitrite reductases (NiRs) are sub-divided into blue and green NiRs which are respectively thought to be redox partners of azurins and pseudoazurins. Crystallographic structures of the blue nitrite reductase from *Alcaligenes xylosoxidans* (*Ax*NiR) in the oxidised and the substrate bound form respectively to 2.1Å and 2.8Å resolution have been published [2]. The 2.1Å resolution of the hexagonal form of *Ax*NiR is presented here allowing a comparison with the crystallographic structures of the green NiRs [3]. There is a striking difference in the overall surface charge distribution between the two sub-groups, providing a structural explanation for their different reactivities to pseudoazurin or azurin and supporting the view that electron transfer proceeds via complex formation.

To investigate the specificity of protein-protein interaction between copper containing NiRs and type 1 copper proteins we have cross reacted proteins from a number of different bacterial species under turnover conditions. Blue NiRs, from *Pseudomonas aureofaciens* and *Ax*NiR, and a green NiR *Alcaligenes faecalis* S-6 NiR were each reacted with cupredoxins from *Alcaligenes xylosoxidan, Alcaligenes denitrificans, Pseudomonasaeruginosa* and *Alcaligenes faecalis* S-6. Progress curve data were collected for each NiR/type 1 copper protein pair in order to compare the efficiency with which reoxidation of the type 1 copper protein occurred.

P11.04.052 THE STRUCTURE OF DI-MANGANESE CATALASE FROM *THERMUS THERMOPHILUS* AT 1.0 Å RESOLUTION. S.V. Antonyuk and W.R. Melik-Adamyan, The Institute of Crystallography, Russian Academy of Sciences, Leninsky pr.59, Moscow 117333, Russia, and A.V.Popov and V.S. Lamzin, EMBL Hamburg Outstation , c/o Desy, Notkestrasse 85, 22603, Germany, and P.M. Harrison and P.J. Artymiuk and V.V. Barynin**,** The Krebs Institute for Biomolecular Research, Department of Molecular Biology and Biotechnology, The University of Sheffield, Sheffield S10 2TN, UK.

Atomic resolution structures have revealed accurate geometries for the active sites of native manganese catalase at pH 8.5, and that of the enzyme inhibited by chloride at pH 5.5. The two data sets were from the cubic crystal form of the enzyme (a=b=c=132 Å, space group $P2_13$, 2 subunits per a. u.) and were collected at 100K to 1.05 and 0.98 Å resolution respectively. The structures of the native di-manganese catalase and of the chloride complex have been refined to an R-factor of 11.2% and 11.5% respectively. The initial model used was that of Mn catalase at room temperature (1.6 Å resolution, R-factor 15.5%) [1].

Di-manganese catalase carries out the disproportionation of hydrogen peroxide. A natural di-manganese active site plays the role of heme of the unrelated heme-containing catalases. It is thought that di-manganese catalase cycles between (Mn^{2+},Mn^{2+}) and (Mn^{3+},Mn^{3+}) states in the catalase reaction [2]. We propose a detailed mechanism for the peroxide disproportionation reaction, based on comparing details of the active centres in the native and inhibited di-manganese catalase structures, which are in the different oxidation states and show important conformational differences.

P11.04.053 CRYSTAL STRUCTURE OF MAMMALIAN CYTOCHROME P450. P.A.Williams, V. Sridhar, J. Cose, E.F. Johnson, D.E. McRee. Dept of Molecular Biology and Department of Experimental Medicine, The Scripps Research Institute, 10550 North Torrey Pines Road, La Jolla, CA 92037, USA

The eukaryotic cytochromes P450 form a broad class of membrane-associated enzymes that catalyse a wide range of monooxygenase reactions. Cytochromes P450 are 50-55kDa haem proteins that play a central role in many synthetic and degradative oxidation reactions with substrates that include fatty acids, prostaglandins, exotins and steroid hormones. P450s are ubiquitous across eukaryotes and prokaryotes. Each P450 is optimised to catalyse a particular monooxygenation reaction, although many exhibit broad substrate specificity. An essential difference between the microsomal and bacterial P450s is the membrane-bound nature of the microsomal P450 as opposed to the soluble nature of the bacterial P450s. It has widely been thought that microsomal cytochromes P450 may receive their substrates from the lipid bilayer as opposed to the cytosol, due to the lipophilic nature of P450 substrates.

We have determined the structure of an engineered microsomal P450 to 3.0Å by the MAD technique using the signal from the single haem iron, supplemented by MIR phases. In addition, data have been collected from several other variants that exhibit a wide range of catalytic activities. The structure of microsomal P450 reveals that while the structure has a conserved core that is very similar to the bacterial structures, there are large differences in structure apparently due to the membrane-association of the microsomal P450. An analysis of the crystal packing contacts suggests an engineering rationale that may be

applied to facilitate the crystallisation of other members of the mammalian cytochrome P450 family.

P11.04.054 CRYSTALLOGRAPHIC STUDIES ON XANTHINE OXIDASE PURIFIED FROM RAT LIVER. A. L. Carvalho, J. M. Dias and S. Teixeira, Departamento de Química, FCT, UNL, 2825-114 Caparica, Portugal and G. Bourenkov, H. Bartunik, Max-Planck Research Unit for Structural Molecular Biology, MPG-ASMB c/o DESY and R. Huber, Max-Planck Institut für Biochemie, 82152 Martinsried, Germany and L. Maia and L. Mira, Faculdade de Ciências, UL, Lisboa, Portugal and M. J. Romão, Departamento de Química, FCT, UNL, 2825-114 Caparica, Portugal.

Xanthine Oxidase from rat liver (a homodimer enzyme of ca 300kDa) has been obtained and attempts to solve the structure are being made. Each of the monomers contains one flavin adenide dinucleotide (FAD), two different kinds of [2Fe-2S] centres and one molybdopterin co-factor. Limited proteolysis has allowed the crystallisation. Two different crystalline forms of the protein were obtained: a cubic-shaped morphology and a star-shaped morphology grown in different crystallisation conditions. Two complete data sets were collected at BW6 beamline of DESY synchrotron (Hamburg, Germany) from the shock-frozen crystals. The cubic-shaped crystals diffracted to 2.6Å resolution and belong to the cubic space group P23 with cell constants a=b=c=156Å. 38122 unique reflections were recorded between 20.0 and 2.6Å with Rmerge=6.9% (26.8% in the outer shell) and a completeness of 97.5% (76.9% in the outer shell). The overall I/sigI was 22.8 while in the outer shell it was 4.8. The star-shaped crystals diffracted to 2.7Å resolution belonging to space group C2 with cell constants a=173.4Å, b=124.1Å and c=109.3Å, with beta=128.4º. 43576 unique reflections were collected between 39.6 and 2.75Å with Rmerge=9.9% (29.5% in the outer shell) and a completeness of 92.6% (77.2% in the outer shell). The overall I/sigI was 15.1 while in the outer shell it was 3.3. Attempts are being made to solve the structure by Molecular Replacement methods using the xanthine oxidase-related aldehyde oxido-reductase (MOP) of Desulfovibrio gigas [1] and the CO-dehydrogenase of Oligotropha carboxidovorans [2].

1. Romão, M. J., Archer, M., Moura, I., Moura, J. J. G., LeGall, J., Engh, R., Schneider, M., Hof, P., Huber, R. (1995) Science, 270, 1170-1176.

P11.04.055 REFINEMENT OF THE ALDEHYDE OXIDO-REDUCTASE FROM *DESULFOVIBRIO GIGAS* (MOP) AT 1.28 Å. J.M. Rebelo, J.M. Dias, M.J. Romão, Departamento de Química, Universidade Nova de Lisboa, 2825-114 Monte da Caparica, Portugal, Gleb P. Bourenkov, Hans D. Bartunick, MPG-ASMB, DESY, Hamburg, Germany, and R. Huber, Max-Planck-Institute für Biochemie, Am Klopferspitz, D-82152 Martinsried, Germany.

The aldehyde oxido-reductase from the sulfate reducing bacterium *Desulfovibrio gigas* (MOP) is a member of the xanthine oxidase family of enzymes (1). MOP has 907 residues on a single polypeptide chain, a MCD cofactor and two [2Fe-2S] centers. Data from improved crystals were collected, and the crystal structure was anisotropically refined at 1.28 Å resolution for 226751 unique reflections. Refinement started with rigid body refinement from a previous 1.8 Å model (2-3). Accurate geometric parameters for the two [2Fe-2S] clusters and for the Molybdopterin Cytosine Dinucleotide – MCD, are now available. The final model contains 12223 atoms and refined to a final R factor of 16.5 and a Rfree of 20.8 for a resolution range (24.4 – 1.28Å). Overall rms bond distances and angles are 0.005 Å and 1.083 Å. Overall comparison of the model quality to the previous one was made. The previous presence of an isopropanol inhibitor molecule near the active site was verified which validates the earlier proposed mechanism. Several Cl^- and Mg^{2+} ions from the crystallization solution and 1246 water molecules were identified.

P11.04.056 X-RAY STUDIES OF A NITRITE REDUCTASE: PRELIMINARY RESULTS. C.A. Cunha, J.M. Dias, G. Almeida, C. Costa, J.J.G. Moura, I. Moura and M.J. Romão, Departamento de Química, Universidade Nova de Lisboa, 2825-114 Monte da Caparica, Portugal, and A. Thompson, European Synchrotron Radiation Facility, BP 220, F-38043 Grenoble Cedex, France

The nitrite reductase (NIR) from *Desulfovibrio desulfuricans* ATCC 27774 performs the dissimilatory reduction of nitrite to ammonia involving a 6 electron reduction (1,2). NIR is a membrane bound enzyme which is induced by growing the bacteria with nitrate rather than sulfate. It has two subunits of molecular masses 63 kDa and 19 kDa as determined by electrospray mass spectrometry as well as is observed by SDS-PAGE. It is thought that each subunit contains five heme groups, one of which is a high-spin ferric heme which is probably the substrate binding site. The oxidized form of this enzyme was crystallised by vapour diffusion, at 20ºC. The crystallization conditions contain PEG as precipitant, $CaCl_2$, HEPES as buffer and zwittergent 3-10. Two crystal forms are obtained. One of them was characterized and belongs to the space group $P2_1$, with unit cell dimensions a=79.0 Å, b=142.5 Å and c=104.3 Å, β=91.26º. MAD data was collected in the iron absorption edge using synchrotron radiation at ESRF. Three data-sets have been collected at the wavelengths 0.9537 Å, 1.7396 Å and 1.7388 Å with a resolution up to 2.8 Å. The overall $I/\sigma(I)$ was 13.8, 9.2 and 9.5 and the overall R_{merge} was 5.3, 7.2 and 7.4, respectively, for each of the data-sets. The structure is being solved using the programs SOLVE and SHARP, and the current state of the analysis will be presented.

P11.04.057 COMBINING CALCIUM-DEPENDENT REGULATION WITH PROTEASE ACTIVITY - CRYSTAL STRUCTURE OF CALPAIN. Christopher M. Hosfield, John S. Elce and Zongchao Jia. Department of Biochemistry, Queen's University, Kingston, ON, K7L 3N6, CANADA.

Calpains are structurally unique enzymes in that they possess cysteine-protease activity that is completely dependent on calcium binding to their two EF-hand domains. Binding of calcium is believed to produce a substantial conformational change, generating an active calpain with the ability to cleave a number of substrates.

Ubiquitous in mammalian tissue, calpains appear to be involved in the cleavage of substrates concerned with cytoskeletal remodeling and signal transduction in response to fluctuations in the intracellular concentration of calcium. Some potential physiological substrates include protein kinase C, p53, spectrin and fodrin.

The crystal structure of this heterodimeric enzyme was determined using MAD with selenium as the anomalous scatterer. In order to facilitate structure determination through multi-crystal

averaging, MAD data were collected on monoclinic and triclinic crystal forms. Electron density maps resulting from a four wavelength experiment on the $P2_1$ crystal, and a two wavelength experiment on the $P1$ crystal were interpretable.

Currently, the fold of the enzyme is visible while most of the backbone and many side chains have been fit into the maps. The structure reveals that the dimerization interface between the catalytic large (80 kDa) subunit and the small (21 kDa) regulatory subunit exists primarily through interactions between the two homologous calcium-binding domains. A linker of approximately 20 residues joins the calcium-binding domain to the remainder of the large subunit, which includes the residues of the catalytic triad at the active site. This linker may act as a trigger for amplification of a calcium-induced conformational change in the large subunit. Structural refinement is in progress, and biological implications will be discussed.

P11.04.058 CRYSTALLOGRAPHIC STUDIES OF D.GIGAS FORMATE DEHYDROGENASE. S. Teixeira, J.M.Dias, A.L. Carvalho, M.J. Almendra, I. Moura, J. Moura and M.J. Romão, Dept. Química, F.C.T., U.N.L., 2825-114 Caparica, Portugal, and G. Bourenkov and H. Bartunik, Max-Planck Research Unit for Structural Molecular Biology, MPG-ASMB c/o DESY, 22603 Hamburg, Germany.

Formate dehydrogenase (FDH) isolated from *Desulfovibrio gigas* catalyses the oxidation of formate to CO_2 , a reaction which involves the release of two electrons. FDH is a periplasmic enzyme constituted of two subunits of 88KDa and 29KDa (SDS-PAGE). It contains two [4FE-4S] clusters and a molybdopterin cofactor composed of two MGD (molybdopterin guanine dinucleotide) units coordinated to a tungsten atom. This is the first example of a tungsten-containing formate dehydrogenase.

The vapour diffusing method was used to obtain the crystals in sitting drops under optimised conditions. Red needle-shaped crystals grew in 1-2 days at 4ºC. Cryo conditions were established and Synchrotron X-Ray data were collected at 100K in the BW6 beamline of the MPG-ASMB in DESY. 163901 unique reflections were collected between 22.59 and 2.03 Å resolution. Data were processed with Denzo and Scalepack in spacegroup $P2_1$ with cell dimensions a = 73.8Å, b = 111.3Å, c = 156.6Å and β =93.7º. An overall $I/\sigma(I)$ of 11.9 was obtained, with an R_{merge} of 7,1% (27% in the outer shell) and a completeness of 99.2% (99.6% in the outer shell). Spectroscopic data suggest that FDH's largest subunit (88KDa) may be homologous to the periplasmic nitrate reductase (NAP, 77KDa), for which the structure has already been solved [1]. Work is currently being done in trying to use NAP to model the FDH's large subunit by molecular replacement.

P11.04.059 CRYSTAL STRUCTURES OF FERRIC-NO COMPLEXES OF FUNGAL NITRIC OXIDE REDUCTASE AND ITS SER286 MUTANTS. S.-Y.Park, S-I.Adachi, E.Obayashi, N.Kamiya, T.Iizuka, Y.Shiro [1], H.Shimizu [2], H.Shoun [3], [1] The Institute of Physical and Chemical Research (RIKEN), RIKEN Harima Institute, Mikazuki-cho, Sayo, Hyogo 679-5143, Japan. [2] Gakushuin University, Mejiro, Toshima-ku, Tokyo 170, Japan. [3] Institute of Applied Biochemistry, University of Tsukuba, Tsukuba, Ibaraki 305, Japan.

Fungal nitric oxide reductase (NOR) is a heam-enzyme catalyzing reduction of NO to N2O through its ferric-NO complex as a first intermediate. Crystal structures of the ferric-NO complex of its wild type, Ser286-->Val and Ser286-->Thr mutant enzymes were determined with 1.7Å resolution at cryogenic temperature (100K).

These are first reports of the ferric-NO complex of heamprotein, showing a linear but slightly tilt NO binding to the heam iron, in sharp contrast to the bent NO coordination in ferrous heamproteins. Replacement of Ser286 with valine or threonine hardly alters the NO coordination structure, but significantly influences positions of water molecules in the active site. Consequently, the hydrogen bond network in the active site is disturbed, in consistency with dramatic loss of the NO reduction reactivity of the enzyme upon the mutations.

We have conclusively defined the water molecule just adjacent to the iron-bound NO as a proton donor to the Fe-NO moiety, and the specific hydrogen bond network including Ser286 as an a proton delivery machinery in the NO reduction reaction by the fungal NOR.

P11.04.060 A PROLINE-SPECIFIC AMINOPEPTIDASE WITH A DINUCLEAR MANGANESE CENTRE. J.M. Guss[1], C.S. Bond[1], N.E. Dixon[2], H.C. Freeman[3], P.W. Lilley[3], J.A. Wilce[1], M.C.J. Wilce[1] and K. Willingham[1], [1]Department of Biochemistry and [3]School of Chemistry, University of Sydney, NSW 2006, Australia, [2]Research School of Chemistry, Australian National University, ACT 0200, Australia.

Proline-specific aminopeptidases cleave the N-terminal residue from oligopeptides in which the penultimate residue is proline. The structure of the *E. coli* enzyme (AMPP) has been solved and refined in two crystal forms using isomorphous and molecular replacement methods [1]. Structures have also been solved for enzyme/inhibitor complexes. AMPP forms tetramers, which persist in both crystal forms. Each monomer has two domains. The active site is entirely located in the C-terminal domain but its surrounds are provided by three of the four subunits.

The heart of the active site is a dinuclear Mn(II) cluster, in which the Mn atoms are separated by 3.3 Å. The metal atoms are bridged by carboxyl groups of protein side chains and a solvent identified from the pH and by analogy with arginase as hydroxide. The structure of the complex with the product-like inhibitor Pro-Leu supports the hypothesis that the bridging hydroxide acts as the nucleophile in the catalytic reaction.

The catalytic domain of AMPP is very similar to the single domain of methionine aminopeptidase (a cobalt enzyme) and the catalytic domain of creatinase (not a metalloenzyme), as predicted from sequence homology [2]. More surprisingly the N-terminal domains of AMPP and creatinase are also similar despite lack of sequence similarity. AMPP also shares a high degree of sequence similarity with both bacterial and mammalian prolidases - proline-aminopeptidases specific for dipeptide substrates.

P11.04.061 STUDIES IN FRUSTRATION : THE STRUCTURE OF BOVINE PORPHOBILINOGEN SYNTHASE. H.L. Carrell, Amy K Katz, Carol E. Afshar, Liat Shimoni-Livny, Trixie Wagner, E.K.Jaffe and Jenny P. Glusker. The Institute for Cancer Research, The Fox Chase Cancer Center, Philadelphia, PA 19111, USA.

The metalloenzyme porphobilinogen synthase (5-aminolevulinate dehydratase) catalyzes the condensation of two molecules of 5-aminolevulinic acid to give porphobilinogen which is the monopyrrole precursor of all biological tetrapyrroles, the porphyrins, corrins, chlorins and other cofactors. The inhibition of PBGS by Pb(II) is known to contribute to neurotoxicity in children. Bovine PBGS is an octameric 280 kD protein consisting of eight subunits (35 kD) with four active sites. Each dimeric

active site binds two functionally distinct types of Zn(II) as well as aminolevulinic acid molecules which have different chemical fates. Bovine PBGS crystallizes from ammonium sulfate at p*H* 6.1 as square parallelopipeds and are tetragonal in space group *I*422 with *a*=125 Å and *c*=200 Å and 4 octameric molecules/cell. Thus there are 2 subunits or 1 dimer in the asymmetric unit. The crystal structures for two modifications of the PBGS have been carried out by molecular replacement using the reported structure of the enzyme from *Saccharomyces cerevisiae*(1). The structure of PBGS with 5-chlorolevulinate covalently bound to four of the eight subunits has been solved to 2.7 Å resolution. The second structure is that of a lead(Pb^{II}) modified enzyme, the crystals of which were discovered to contain no metal ions at all, and thus are apo-PBGS. The structure for this form of the protein has been determined to 2.3 Å resolution. The structural details and a comparison of the structure with the previously reported structures will be presented and discussed. "Where have all the metals gone?" is a question to be pondered and perhaps answered.

Acknowledgment. This work was carried out under grant CA-10925 from the National Institutes of Health.

P11.04.062 WHICH FUNCTIONAL GROUPS DOES A DIVALENT METAL ION MOST LIKE TO BIND TO: STRUCTURE AND ENERGETICS. Jenny P. Glusker, Amy K. Katz, H. L. Carrell, Liat Shimoni-Livny, Trixie Wagner, Carol E. Afshar, Philip George [1], Charles W. Bock [2], [1] The Institute for Cancer Research, The Fox Chase Cancer Center, Philadelphia, PA 19111, USA, [2] The Philadelphia College of Textiles and Science, Philadelphia, PA 19144, USA

The roles of divalent metal ions in biological systems form the basis of this study. Their coordination chemistry has been investigated by analyses involving the Cambridge Structural Database, the Protein Data Bank and ab initio molecular orbital calculations. The metal ions described here include magnesium, calcium, manganese, zinc, copper, and lead. Each divalent ion shows a specific preference for binding directly to oxygen, nitrogen and/or sulfur in liganding groups in proteins. Methods for analyzing and representing this are introduced, together with the resulting data obtained for the ions listed above.

The roles of divalent metal ions in biological systems form the basis of this study. Their coordination chemistry has been investigated by analyses involving the Cambridge Structural Database, the Protein Data Bank and ab initio molecular orbital calculations. The metal ions described here include magnesium, calcium, manganese, zinc, copper, and lead. Each divalent ion shows a specific preference for binding directly to oxygen, nitrogen and/or sulfur in liganding groups in proteins. Methods for analyzing and representing this are introduced, together with the resulting data obtained for the ions listed above.

The extent to which the coordination number in the innermost coordination shell around a divalent metal ion can be changed as a ligand, such as a water molecule, moves between its inner and second coordination shell has been investigated; this is relevant to many biochemical reactions that occurs at the metal site in an enzyme. The energetic consequences were determined by molecular orbital calculations. These energy changes are low for zinc and calcium, but are high for magnesium and divalent manganese. These findings have implications for the roles of the metal ions in biochemical reactions and have been further investigated by analyses of proposed metalloenzyme mechanisms and their crystal structures listed in the Protein Data Bank.

Any effect of the metal ion on the ligand, such as polarization, is also relevant to the catalytic mechanisms of metalloenzymes. First the ability of the divalent metal ion to ionize water has been investigated by ab initio molecular orbital calculations. This gives a relative scale of the polarizing abilities of the various metal ions. Then the extent to which the polarizing ability of the metal ion is a function of its immediate ligands in the first coordination sphere has been analyzed. For example, the replacement of a water molecule in the inner coordination sphere by a carboxylate group reduces the ability of the metal ion to polarize water. Finally the propensity of certain metal ions to take part in specific structural motifs on binding to an enzyme, and the utility of such motifs to the action of the enzyme, are described.

This work was supported by a grant CA-10925 from the National Institutes of Health, US Public Health Service.

P11.04.063 THE ROLE OF IRON BINDING DEDUCED FROM CRYSTAL STRUCTURES OF PHENYLALANINE HYDROXYLASE. T. Gleichmann, I.G. Jennings, R.G.H. Cotton, B. E. Kemp and B. Kobe, Structural Biology Laboratory, St. Vincent's Institute of Medical Research, 41 Victoria Parade, Fitzroy, Victoria 3065, Australia.

The mononuclear non-heme iron dependent enzyme phenylalanine hydroxylase (PheOH, phenylalanine 4-monooxygenase) catalyses the hydroxylation of phenylalanine to tyrosine in the presence of 6(R)-L-*erythro*-tetrahydrobiopterin (BH_4) and dioxygen. This is the rate limiting step in phenylalanine catabolism and neurotransmitter biosynthesis. Phenylalanine is both an essential amino acid and toxic at pathophysiological levels. Consequently, defects in PheOH cause hyperphenylalaninemias (HPA) including phenylketonuria (PKU), a common metabolic disorder that can result in severe mental retardation. Likewise, the enzyme is tightly regulated by phenylalanine activation, phosphorylation, BH_4 inhibition and at the transcriptional level. PheOH is a member of the family of aromatic amino acid hydroxylases that also include tyrosine hydroxylase and tryptophan hydroxylase. They all consist of a regulatory, a catalytic and tetramerization domain; in solution PheOH exists as a mixture of dimeric and tetrameric forms.

To assess the structural determinants of iron-binding we have determined structures of phosphorylated, C-terminally truncated, dimeric PheOH (PheOH-24) in apo-, Fe- and In-bound states. The iron incorporated in the expressed protein can be extracted with 1,10-phenanthroline from the Fe-PheOH-24 crystals yielding apo-PheOH-24 crystals and subsequently replaced by In^{3+} using the soaking technique to yield In-bound crystals. All three crystal forms are isomorphous and have the symmetry of spacegroup $P4_322$. Both the metal-free apo- and In-bound structures represent catalytically inactive forms of PheOH.

The iron is bound at the floor of a deep pocket in the catalytic domain, octahedrally coordinated by His285, His290, Glu330 and three water molecules. The coordination geometry for In^{3+} in In-PheOH and a similarly located water molecule in apo-PAH are comparable to iron in the native form, with shorter distances to In^{3+} and longer distances to the water molecule as compared to the native PheOH. The Glu330 changes the ligation mode: bidendate for In-PheOH, monodendate for apo-PheOH and a mixture of both for the native PheOH.

The metal ion forms a hypothetical high valent iron-oxo intermediate, which is postulated to react with phenylalanine in the hydroxylation process. In contrast, In is unable to substitute for Fe during the reaction.

P11.04.064 COMPARISON OF ZINC LIGAND COORDINATION OF MATRIX METALLOPROTEASES AND INHIBITOR COMPLEXES Karl D. Hardman, DuPont Pharmaceuticals Company, Experimental Station E353/148H, Wilmington, DE 19880-80353, USA

The coordination geometries of high resolution crystal structures (better than 1.7 Ang.) of the catalytic zinc sites for a number of Matrix-Metalloprotease (MMP)/ inhibitor complexes have been compared with other zinc proteases and small molecule

zinc complexes. The purpose was to establish if different inhibitors with the same coordination ligands but different interactions with the protein imposed any significant alteration of the coordination geometry of the zinc.

In addition, positions of neighboring side chains which are not zinc ligands were compared to estimate their contributions to catalysis and/or electronic stability of the active site. For example, the conserved methionine of the metzincin (thimet) classes of zinc proteases plays an unknown role in the structure and catalysis. Previous considerations of the catalytic mechanism of these proteases have not addressed possible effects of this thioether group. However, mutation of this side chain to serine has resulted in approximately a 100-fold loss in activity against a peptide substrate in MMP3 (stromelysin-1).

P11.04.065 CRYSTAL STRUCTURE OF HUMAN PHENYLALANINE HYDROXYLASE IN NATIVE AND INHIBITOR BOUND FORMS. H. Erlandsen and R. C. Stevens, Department of Chemistry, University of California, Berkeley, CA. 94720, USA, T. Flatmark, Department of Biochemistry and Molecular Biology, University of Bergen, Årstadveien 19, N-5009 Bergen, Norway, and E. Hough, Protein Crystallography Group, Chemistry Department, University of Tromsø, N-9037 Tromsø, Norway.

The non-heme, iron dependent metalloenzyme, mammalian phenylalanine hydroxylase (EC 1.14.16.1, phenylalanine 4-monooxygenase, PheOH) catalyzes the hydroxylation of l-phenylalanine to l-tyrosine in the prescence of 6(*R*)-L-erythro-5,6,7,8-tetrahydrobiopterin and dioxygen, the initial and rate-limiting step in the catabolism of this amino acid [1]. Phenylketonuria (PKU) is an autosomal recessive disease caused by mutations in the PheOH gene, which results in considerable heterogeneity both in terms of clinical, metabolic and enzymatic phenotypes. More than 280 different PKU mutations have been reported so far. The mechanism with which the hydroxylation occurs is not yet fully understood, but the enzyme is believed to proceed through an ordered binding of tetrahydrobiopterin, molecular oxygen and phenylalanine substrate. ^{18}O kinetic isotope effect measurements [2] suggest a one-electron transfer from the tetrahydrobiopterin to oxygen to form a superoxide anion as the first reactive. This radical pair would then couple to form a 4a-peroxytetrahydrobiopterin intermediate. The crystal structure of a truncated form of hPheOH (containing the catalytic domain) has been solved to 2.0Å resolution in its native, iron containing state and also in catecholamine (dopamine, noradrenaline and adrenaline) inhibitor bound states. Crystallographic studies of this enzyme and its binding of inhibitors, substrate and co-factor, will help elucidate the molecular basis of their binding to the active site, as well as give a structural rationale for the PKU mutations.

P11.04.066 CRYSTAL STRUCTURE OF A DIOXYGENASE LIGAB WHICH IS A PROTOCATECHUATE 4,5-DIOXYGENASE. K. Sugimoto, T. Senda, H. Aoshima, E. Masai, M. Fukuda and Y. Mitsui, Department of BioEngineering, Nagaoka University of Technology, Nagaoka, Niigata 940-2188, JAPAN

Sphingomonas paucimobilis SYK-6 utilizes an extradiol type catecholic dioxygenase, LigAB (a protocatechuate 4,5-dioxygenase), to oxidize protocatechuate (PCA). The enzyme belongs to the family of class III extradiol type (catecholic) dioxygenase catalyzing the ring opening reaction of protocatechuate and related compounds. Primary structure of LigAB has suggested that the enzyme has no evolutionary relationship with the family of class II extradiol type dioxygenase for which the crystal structures have been determined for several member enzymes. Both the class II and class III enzymes utilize non-heme ferrous center to catalyze the addition of dioxygen to its substrate. Through elucidating the crystal structure of LigAB, we aim at providing a structural basis for discussing the function of the class III enzymes in general and comparing structures and functions between the class II and class III enzymes.

The crystal structure of LigAB was determined using an MIR method. Subsequently the crystal structure of LigAB in complex with a substrate, PCA, was determined. The three-dimensional structure of LigAB is completely different from that of the class II extradiol type dioxygenases. This implies that, as implicated by primary structure comparison, no evolutionary relationship exists between the classes II and III enzymes. The iron coordination sphere of LigAB in complex with its substrate, however, shares many geometrical characteristics to that of class II enzymes. Moreover the disposition of the putative catalytic base relative to the coordination sphere is very similar between the two kinds of enzymes. These results strongly suggest that the classes II and III enzymes share a common catalytic mechanism despite the completely different three-dimensional structures. Thus the present case appears to be another clear example of convergent evolution of two proteins having no overall sequence and structural similarity to each other.

P11.04.067 THE STRUCTURES OF 5-AMINOLAEVULINATE DEHYDRATASE FROM *E. COLI* AND YEAST. P.T. Erskine, E.Norton, P.M. Shoolingin-Jordan, S.P. Wood and J.B. Cooper. School of Biological Sciences, University of Southampton, Southampton, SO16 7PX, UK, and R. Newbold and M.J. Warren. Institute of Ophthalmology, London, EC1V 9EL, UK.

5-aminolaevulinate dehydratase (ALAD, porphobilinogen synthase) is a key early enzyme of the porphyrin and corrin biosynthetic pathways which catalyses the condensation of two 5-aminolaevulinic acid (ALA) molecules to form the pyrrole porphobilinogen (PBG). The yeast ALAD structure (solved at 2.3 Å by MAD at ESRF, Grenoble with Dr A. Thompson [1]) was used to solve the *E. coli* enzyme at 2.0 Å by molecular replacement [2]. Both ALADs form large homo-octameric structures with 422 symmetry in which each subunit adopts the TIM-barrel fold with a 20-30 residue N-terminal arm forming extensive inter-subunit interactions. Pairs of monomers associate with their arms wrapped around each other to form compact dimers. Four dimers interact principally via their arm regions to form the octamer which has all eight active sites exposed on the surface. At the base of each active site are two lysine residues (195 and 247 in *E. coli* numbering), one of which, Lys 247, forms a Schiff base link to the substrate ALA. Close by is the catalytic zinc binding site formed by three cysteines (Cys 120, 122 and 130) and a solvent molecule. The *E. coli* enzyme possesses another well defined zinc binding site in which the metal ion is coordinated by Glu 232 and five solvent molecules buried at a subunit interface. This octahedrally coordinated metal binding site and its proximity to the active site may account for the activating properties which magnesium ions have on the enzyme. The structure of the inhibitor laevulinic acid bound to both ALADs [2, 3] reveals that a large loop covering the active site (residues 197-220) undergoes a substantial ordering on binding the inhibitor.

P11.04.068 THE STRUCTURE OF A CLASS II ALDOLASE COMPLEXED WITH PGH REVEALS DETAILS OF MECHANISM AND SPECIFICITY. William N. Hunter, David R. Hall, Department of Biochemistry, University of Dundee, Dundee, DD1 5EH, United Kingdom, Gordon A. Leonard, Joint Structural Biology Group, ESRF, BP 220, F38043 Grenoble CEDEX, France, Christopher D. Reed, C. Ian Watt, Department of Chemistry, University of Manchester, Oxford Road, Manchester, M13 9PL, United Kingdom, and Alan Berry, School of Biochemistry and Molecular Biology, University of Leeds, Leeds, LS2 9JT, United Kingdom.

The structure of a Class II fructose-1,6-bisphosphate aldolase in complex with the substrate analogue and inhibitor phosphoglycolohydroxamate (PGH) has been determined using X-ray diffraction terms to a resolution of 2.0Å. PGH resembles the ene-diolate transition state of the physiological substrate dihydroxyacetone phosphate. It is well ordered and bound in a deep polar cavity at the C-terminal end of the $(\alpha/\beta)_8$ barrel where it chelates the catalytic zinc ion using hydroxyl and enolate oxygens. Trigonal bipyramidal coordination of the zinc is completed by three histidines. A complex network of hydrogen bonds occurs at the catalytic centre and are required to organise the position of key functional groups and metal ion ligands. A well defined monovalent cation binding site is observed following significant re-organisation of loop structures. This assists the formation of a phosphate binding site on one side of the barrel that tethers PGH in the catalytic site. The positions of functional groups of substrate and putative interactions with key amino acids are identified. Knowledge of the complex structure complements spectroscopic and site-directed mutagenesis studies and contributes to the understanding of the mechanism and substrate specificity of this family of enzymes. A reaction mechanism distinct from that of other Class II aldolases is proposed. The results suggest that the Class II aldolases should be sub-divided into two groups on the basis of both distinct folds and mechanism.

P11.04.069 THE STRUCTURE OF DI-MANGANESE CATALASE FROM *LACTOBACILLUS PLANTARUM* AT 1.8 Å RESOLUTION. V.V. Barynin and P.M. Harrison and P.J. Artymiuk , The Krebs Institute for Biomolecular Research, Department of Molecular Biology and Biotechnology, The University of Sheffield, Sheffield S10 2TN, UK, and S.V. Antonyuk, The Institute of Crystallography, Russian Academy of Sciences, Leninsky pr.59, Moscow 117333, Russia, and V.S. Lamzin, EMBL Hamburg Outstation , c/o Desy, Notkestrasse 85, 22603, Germany, and M.M. Whittaker and J.W. Whittaker, Dept. of Biochemistry and Mol. Biology, Oregon Graduate Institute, Portland, OR 97291-1000, USA

The *L. plantarum* catalase structure has confirmed the hexameric nature of this enzyme with a novel arrangement of di-Mn catalase domains in the monomer. The first coordination sphere of the di-Mn cluster in the active site is composed of three Glu and two His ligands. Only the His ligands and a (Mn,Mn) bridging Glu have the same geometry as the equivalent *T.thermophilus* manganese catalase residues. The positions of the Mn-monodentate Glu's of the active site are different. There are also three solvent ligands to Mn's. Both the Mn ions of the *L. plantarum* catalase active site are six-coordinate. The data set was obtained from the monoclinic crystal form of the native enzyme (a=75.5, b=97.6, c=108.0 Å, α=90.0, β=107.2, γ=90.0, space group $P2_1$, 6 subunits per a. u.) and was collected at 293K to 1.84 Å resolution. The structure has been solved by molecular replacement. The initial model used was that of a core of the *T.thermophilus* manganese catalase hexamer structure [1]. The structure of the *L. plantarum* catalase has been refined to an R-factor of 14.8% (free R of 20.3%). Comparison of the *L. plantarum* and *T.thermophilus* catalase structures has revealed that there are two distinct but related subfamilies of catalase in the manganese catalase family with different design of the hexamers and the active sites.

1. V.V.Barynin, P.D.Hempstead, A.A.Vagin, S.V.Antonyuk, W.R.Melik-Adamyan, V.S.Lamzin, P.M.Harrison & P.J.Artymiuk, (1997) J.Inorganic Biochem. 67, 196.

P11.04.070 CRYSTAL STRUCTURES OF FRAGMENTS TR_1C AND TR_2C FROM CALMODULIN L-L. Olsson and L. Sjölin, Dept. of Inorganic Chemistry and the Centre for Structural Biology, University of Göteborg, SE-412 96 Göteborg, Sweden

Calmodulin is a relatively small calcium binding protein, involved in the regulation of several biochemical processes in various organisms. The 148 amino acids are folded into two globular domains connected by a long solvent exposed alpha-helix. Each domain has a large hydrophobic cleft and two EF-hands, the characteristic helix-loop-helix motifs in calcium binding proteins, and each EF-hand binds one Ca^{2+} ion.

The fragments, which were expressed in E. coli, consist of amino acids 1 to 75 (tr_1c) and amino acids 76 to 148 (tr_2c). Tr_1c crystallizes in the space group $C222_1$ with unit cell dimensions a=34.5 Å, b=67.7 Å and c=60.0 Å, and data were collected to 1.8 Å resolution. Tr_2c crystallizes in the space groups $P4_32_12$ and $P4_3$ and also in yet another tetragonal space group with a=b=61.5 Å and c=73.2 Å. This crystal diffracts to 1.5 Å resolution. These structures were solved using rotation/translation functions, with the two calmodulin domains as models.

Comparisons between the X-ray structures of the whole calmodulin molecule and tr_1c and tr_2c, respectively, show that the structure of one single domain is not largely dependent on the second domain. This is advantageous since, for example, dynamic studies with NMR are more convenient with smaller molecules. The globular fragments contain two Ca^{2+}-binding EF-hands each, and the hydrophobic clefts observed in calmodulin are also found in these fragments.

The structures of tr_1c and tr_2c will be presented, and compared with the parent calmodulin structure.

P11.04.071 METALLO-β-LACTAMASE FROM B. CEREUS 569/H: MONO- OR BI-NUCLEAR ENZYME? Stella Maris Fabiane, M. K. Sohi, B. J. Sutton, Molecular Biology and Biophysics Group, The Randall Institute, King's College London, 26-29 Drury Lane, London WC2B 5RL, UK.

Elucidation of the mechanism of metallo-β-lactamases is an important step in the production of drugs to counteract bacterial resistance to β-lactam antibiotics. Following the structure determination of the metallo-β-lactamase from *B. cereus* 569/H/9 at 1.9Å [1], its active site structure has now been probed by changing the pH of the crystals.

At pH 5.2, there are two Zn^{2+} ions in the active site. The first of these, Zn1, has a high affinity to the protein (1μM) and the second, Zn2, has a low affinity (24mM). When the pH of the crystal is raised to 6.0, the structures solved in two different space groups at 1.7Å (crystal grown from ammonium sulphate, space group $P3_121$, R_{cryst}=20%) and 1.9Å (crystal grown from PEG 8000, space group C2, R_{cryst}=24.2%) show that Zn2 has moved out of the active site and the previously co-ordinating cysteine (Cys168) residue is oxidised to the sulfinic form, SO_2. The same is true for crystals transferred to pH 7.5 (2.0Å, space group $P3_121$, R_{cryst}=18.1%). There is also considerable movement of another of the ligands to Zn2, His210. These data indicate that there are substantial conformational and chemical changes in the active site depending upon pH, throughout the pH range over which the enzyme is active.

All structures, whether mono- or bi-zinc, reveal a water molecule tightly bound to Zn1, which is the probable nucleophile for β-lactam ring hydrolysis. A catalytic mechanism is proposed.

[1] Fabiane *et al.* (1998). Biochemistry, **37**, 12404-12411.

P11.04.072 1.27Å CRYSTAL STRUCTURE OF RUSTICYANIN AND POINT MUTATIONS OF SER86 AND MET148. Ian Harvey [1], John Hall [2], Lalji Kanbi [1,2], S. Samar Hasnain [1,2], [1] Syncrotron Radiation Department, CLRC Daresbury Laboratory, Warrington, WA4 4AD, UK, [2] Faculty of Applied Sciences, De Montfort University, Leicester, LE1 9BH, UK

Rusticyanin is the highest redox potential single blue copper protein, from the acidophilic chemolithotroph Thiobacillus ferrooxidans. Its crystal structure has been determined and refined to 1.27Å resolution using SHELX with anisotropic temperature factors. Errors have been determined by full matrix inversion. This is the only single blue copper protein which has been determined to this resolution and is refined in this way. A number of mutants have been expressed in E.coli, including mutations at Met 148 and Ser86 (Asp, Asn,Gln, Leu). This residue is adjacent to the copper ligand His85 and is a conserved Asn in other blue proteins. The oxidised form of all four Ser mutants are less acid stable than the wild-type protein, although the mechanism of lability varies. These mutations modulated the redox potential by more than 110 mV. The characteristics of these mutants support the idea that this residue is in part responsible for the acid stability and redox potential.

Similarly, the Met 148 ligand has been mutated to Leu, Lys, Glu & Gln showing remarkable variation in clour & redox potential. The effect of these mutations would be discussed in the light of our 1.27Å resolution crystallographic structure of Rusticyanin.

P11.04.073 CRYSTAL STRUCTURE OF *PORPHYRA YEZOENSIS* CYTOCHROME c_6. Tomokazu Sasaki, Akira Uchida and Isao Oonishi, Department of Biomolecular Science and Fuminori Yoshizaki, Department of Biology, Faculty of Science, Toho University, Miyama, Funabashi 274-8510, Japan

Cytochrome c_6 transfers electrons from the cytochrome b_6f complex to the cytochrome *P700* in photosynthesis. The protein is a small type cytochrome *c*. Plastocyanin is also known to have the same function as cytochrome c_6, but no structural similarities are recognized between them. Cytochrome c_6 contains a heme prosthetic group which is mainly composed of alpha helices, while plastocyanin, a copper containing protein, is largely made up of beta sheets. Some algae have the ability to synthesize both cytochrome c_6 and plastocyanin; cytochrome c_6 replaces plastocyanin when copper is deficient, while other algal species synthesize either cytochrome c_6 or plastocyanin solely. The red alga *Porphyra yezoensis* has only cytochrome c_6 of 85 amino acid residues with a redox potential of 342 mV.

Two crystal forms with good quality for X-ray diffraction have been obtained. The crystals belong to the space group $P2_12_12_1$ with cell dimensions a=46.7, b=49.5 and c=37.1≈ (orthorhombic form) and the space group $P4_32_12$ with cell dimensions a=48.2 and c=83.0 ≈ (tetragonal form). Each crystal form has one molecule in an asymmetric unit. The structure of cytochrome c_6 in each crystal form was solved by molecular replacement and refined by simulated annealing.

The cytochrome c_6 in each form has almost the same structure, being very similar to those of other algal species; two long alpha helices at both ends of the chain cross at nearly right angles to each other and the heme is covalently linked to the two cysteine residues. Dimerization about the heme crevice is found in tetragonal crystal form, whereas no such dimerization is present in orthorhombic form.

P11.04.074 IRON SUPEROXIDE DISMUTASE FROM THE HYPERTHERMOPHILE SULFOLOBUS SOLFATARICUS. T. Ursby, LCCP, IBS, 41 avenue des Martyrs, F-38027 Grenoble Cedex 1, France and S. Al-Karadaghi, Molecular Biophysics, Center for Chemistry and Chemical Engineering, Lund University, P.O.Box 124, S-22100 Lund, Sweden and B.S. Adinolfi, E. De Vendittis and V. Bocchini, Dipartimento di Biochimica e Biotecnologie Mediche Università di Napoli Federico II, Via S. Pansini 5, I-80131 Naples, Italy.

We have determined the structure of superoxide dismutase (SOD) from the hyperthermophile *Sulfolobus solfataricus* to 2.3 Å resolution by molecular replacement (R_{cryst} 16.8%, R_{free} 19.8%) [1]. There are two identical monomers in the asymmetric unit (space group C2; a=76.3 Å, b=124.3 Å, c=60.3 Å, β = 128.8º). The monomer has a molecular weight of 24 kDa and consists of 210 amino acid residues of which 205 are visible in the electron density map. The overall fold of the monomer of *S. solfataricus* SOD is similar to that of other known Fe or Mn-SODs. *S. solfataricus* SOD forms a very compact tetramer of a type similar to that of SOD from the hyperthermophile *Aquifex pyrophilus* [2]. Both structures show an elevated number of inter-subunit ion-pairs compared with the mesophilic SOD from *Mycobacterium tuberculosis* and the thermophilic SOD from *Thermus thermophilus*. However, in contrast to the *A. pyrophilus* SOD structure, the number of intra-subunit ion-pairs and inter-subunit hydrogen bonds is not higher than in the compared mesophilic and thermophilic SOD structures. The electron density also revealed an unexpected and unusual covalent modification of a conserved tyrosine in the active site. The modification was shown to lower enzyme activity.

P11.04.075 TOWARD IMPROVED BIODEGRADATION OF PCBS: STRUCTURES OF COMPONENTS OF BIPHENYL DIOXYGENASE. Christopher L. Colbert, Mathew Chakko, Giuseppe Terracina, and Jeffrey T. Bolin Dept. of Biological Sciences, Purdue University, West Lafayette, IN 47907-1392, USA

The first step in the aerobic microbial degradation of biphenyl and polychlorinated biphenyls (PCBs) utilizes a short electron transfer chain to facilitate dioxygenase-catalyzed formation of a *cis*-dihydrodiol from the aromatic substrate. The electron transfer chain includes a ferredoxin reductase (BphG), a Rieske-type ferredoxin (BphF), and the ring-hydroxylating dioxygenase ($BphA_1A_2$). We determined the structures of the ferredoxin from *Burkholderia cepacia* to 1.6Å resolution and the biphenyl dioxygenase from *Comomonas testosteroni* to 2.2Å resolution in the absence of O_2. Intrinsic Fe atoms provided MAD phasing information in both cases.

The structure of BphF is the first for a dioxygenase ferredoxin (Fd) and affords an opportunity for comparisons with Rieske subunits from other systems. For the refined model, R_{work}=20.6% and R_{free}=22.7%. The redox properties of dioxygenase Fds differ significantly from those of the Rieske proteins of the bc_1 (mitochondria) and the b_6f (chloroplasts) complexes: the midpoint potentials of the former are ~450mV lower and are relatively independent of ionic strength and pH. Others proposed that differences in the accessibility of the clusters are the cause of these variations, and that the Fe_2S_2 cluster of the dioxygenase Fd was likely to be sequestered. Despite low

sequence identity and variations in key segments of the cluster binding domain, BphF clearly shows a remarkable overall similarity to the bc_1 and b_6f structures, and the Fe_2S_2 cluster has equivalent solvent accessibility. Therefore, the differences in redox properties must arise from other factors. The BphF system allows for a detailed study of the subtleties of protein control of redox potential using mutagenesis coupled to biochemical, structural, and computational studies.

Biphenyl dioxygenase is an $\alpha_3\beta_3$ heterohexamer. Each α subunit binds one Rieske Fe_2S_2 cluster and catalyzes ring-hydroxylation at a mononuclear, non-heme Fe(II) active site. Comparison of the biphenyl and naphthalene dioxygenases provides insight into key aspects of structure and catalysis. Moreover, the structure of biphenyl dioxygenase can be used in conjunction with that of BphF to identify features involved in protein-protein association and electron transfer.

Support from NIH grant R01-GM52831 is gratefully acknowledged.

P11.04.076 STRUCTURE AND REACTION MECHANISM OF GLYOXALASE II Alex D. Cameron[‡], Marianne Ridderström[§], Birgit Olin[§], Bengt Mannervik[§] and T. Alwyn Jones[¶], [‡]Dept. of Chemistry, University of York YORK, YO10 5DD; Departments of Molecular Biology[¶] and Biochemistry[§], Uppsala University, Biomedical Center, Box 590, S-751 24, Uppsala, Sweden.

Glyoxalase II is the second of two enzymes in what has been termed the glyoxalase system. The physiological role of this system appears to be to detoxify methylglyoxal which is produced as a byproduct of glycolysis. With the use of glutathione as coenzyme the methylglyoxal is converted to D-lactic acid. Glyoxalase II, a thiolesterase, catalyses the conversion of D-lactoylglutathione which is produced by glyoxalase I to form D-lactic acid and glutathione. Recently it has been reported that glyoxalase II is a member of a family that includes the metallo-β-lactamases (MBLs), of which the structure is known. The MBLs contain either a mono or a binuclear zinc binding site. Conservation amongst the family, of the residues involved in binding the zinc in the MBLs, suggested that glyoxalase II may be a metalloenzyme.

We have solved the structure of human glyoxalase II by SIRAS. The enzyme consists of two domains. The N-terminal domain is built up of a 4 layered β-sandwich. It is this domain which is similar to the MBLs. This includes the bi-nuclear metal binding site which was apparent in the associated electron density maps at one edge of the β-sandwich. The C-terminal domain, not found in the MBLs, is built mainly of α-helices. The active site is situated at the domain interface. We have succeeded in soaking a substrate analogue into the active site. The position of the analogue next to the metal centre suggests a mechanism for hydrolysis in which a water molecule shared between the two metal ions acts as a nucleophile in the reaction. Such a proposal was also made for the the MBLs but without the crystallographic evidence of a substrate analogue in the active site.

P11.04.077 HIGH RESOLUTION STRUCTURE OF THE ACTIVE SITE OF THE HEMOPROTEIN FROM SULFITE REDUCTASE. M. E. Stroupe, B. R. Crane, and E. D. Getzoff, The Scripps Research Institute, La Jolla, CA 92037, USA.

The chemical properties of metalloenzymes are related to the detailed structure of the metallic cofactors used in catalysis. Sulfite Reductase (SiR) catalyses the six electron reduction of sulfite to sulfide by coupling the reducing power of two flavin molecules to a redox-active Fe_4S_4 cluster and an iron-containing siroheme (of the bacteriochlorin class). Each of eight 66-kDa flavoproteins that make up the holoenzyme contain one FAD and one FMN [1]. The four 64-kDa hemoproteins complete the holoenzyme and couple the Fe_4S_4 cluster to the siroheme through an endogenous cysteine ligand [2]. The 1.6 Å resolution structure of the hemoprotein suggests that structural perturbations in the Fe_4S_4 cluster and the siroheme may play a role in driving the reduction of sulfite by facilitating cofactor coupling [3]. Using high-intensity synchrotron radiation and frozen crystals, a higher resolution structure is attainable. The non-canonical geometry of its metal cofactors reveals how the SiR protein environment contorts the inorganic compounds to efficiently perform a complex chemical process.

P11.04.078 CRYSTAL STRUCTURE OF CATECHOL 2,3-DIOXYGENASE (METAPYROCATE CHASE) FROM PSEUDOMONAS PUTIDA MT-2. A. Kita*, S. Kita**, I. Fujisawa*, K. Inaka**, T. Ishida***, K. Horiike***, M. Nozaki***, K. Miki*, *Department of Chemistry, Graduate School of Science, Kyoto University, Sakyo-ku, Kyoto 606-8502, Japan, **Research Laboratory of Resources Utilization, Tokyo Institute of Technology, Nagatsuta, Midori-ku, Yokohama 226-8503, Japan, ***Department of Biochemistry, Shiga University of Medical Science, Seta, Ohtsu, Shiga 520-2192, Japan

Catechol dioxygenases have a key role in the degradation of aromatic moelcules in the environment by soild bacteria. Catechol 2,3-dioxygenases catalyze the incorporation of dioxygen into catechol and the extradiol ring cleavage to form 2-hydroxymuconate semialdehyde. Catechol 2,3-dioxygenase (metapyrocatechase, MPC) from Pseudomonas putida mt-2 was the first extradiol dioxygenase to be obtained in a pure form and has been studied extensively. MPC is a tetramer of identical subunits, each with a single non-heme ferrous ion and 307 amino acids; the enzyme is designated as (a-Fe2+)4. Crystals of MPC enough for X-ray work were obtained from sodium citrate solution by vapur-diffusion procedure with direction-restricted stepwise seeding method at 4°C [1]. The three-dimensional structure of MPC has been determined at 2.8Å resolution by the multiple isomorphous replacement method [2]. The crystallographic R and free R (5% subset) factors for the reflections between 10 to 2.8Å resolution are 0.200 and 0.280, respectively. The structure shows that the four subunit molecules are related by a noncrystallographic 222 symmetry. The monomer comproses N-terminal and C-terminal domains, which are structurally similar to each other and related by a local twofold axis. The structure of the MPC subunit resembles that of 2,3-dihydroxybiphenyl dioxygenase, although there is low amino acid sequence identity between these enzymes. The active site structure reveals a distorted tetrahedral Fe(II) site with three endogenous ligands (His153, His214, and Glu265) and an additional molecule that is most probably acetone. The present MPC structure shows that the putative acetone molecule is directly ligated to the iron atom to block the Fe(II) binding sites.

P11.04.079 STRUCTURES OF SUBUNITS IIIA AND IV ILLUMINATE COOPERATIVE OXYGEN BINDING BY LIMULUS HEMOCYANIN. Karen A. Magnus [1], Shenping Liu [2], [1] Department of Biochemistry, Case Western Reserve University School of Medicine, Cleveland, OH 44106, USA, [2] Department of Biochemistry, Case Western Reserve University School of Medicine, Cleveland, OH 44106, USA - present address: Department of Chemistry, Cornell University

The structures of subunits IIIa and IV of Limulus polyphemus (horseshoe crab) hemocyanin were determined by molecular replacement using the backbone structure of subunit II (1OXY) as the test molecule. Because both crystal forms have large unit cells, data were collected at the Cornell High Energy Synchrotron Source. Phases for the oxygenated hemocyanin subunit IV were improved by averaging, solvent flattening and histogram matching. The resultant electron density map was of sufficient quality that the identities of many amino acids could be seen. The dicopper active site of subunit IV is the same as in subunit II. Interestingly, subunit IV hemocyanin also has density at the same position postulated to be an allosteric effector in subunit II, suggesting the possibility of a general cooperative mechanism for all arthro- pod hemocyanins. Hemocyanin subunit IIIa is the only Limulus subunit capable of catalyzing the decomposition of hydrogen peroxide. This subunit does not have the key "oxygen sensor" phenylalanine at its position 49, thus conferring special properties on its active site.

Supported by NSF MCB9305250 and MCB9817090.

P11.04.080 CRYSTALLIZATION AND PRELIMINARY CRYSTALLOGRAPHIC ANALYSIS OF ACONITASE FROM THERMUS THERMOPHILUS HB8. Hiroshi Aoyama, Shin-ichi Kawaguchi, Yorinao Inoue [1], Minori Kuraishi, Seiki Kuramitsu [2]. [1] SPring-8, The Institute of Physical and Chemical Research (RIKEN), 323-3 MIkazuki-cho, Mihara Sayo, Hyogo 679-5143, Japan, [2] Graduate School of Science, Osaka University, 1-1 Machikaneyama-cho, Toyonaka, Osaka 560-0043, Japan

Aconitase [citrate(isocitrate) hydrolyase, EC 4.2.1.3] catalyzes the stereospecific conversion of citrate to isocitrate via cis-aconitate in the tricarboxylic acid cycle. The enzyme contains iron-sulfer cluster, which functions as not redox reaction but hydratases.

We crystallized aconitase by a hanging-drop vapor diffusion method. Crystals were grown in 100 mM Hepes buffer at pH 7.0, using ammonium sulfate as a precipitant. They belong to the orthorhombic system, with unit cell dimensions of a=95.4, b=170.3, c=185.5Å.

X-ray data collection were carried out at beamline BL45XU of SPring-8. The crystal diffracts beyond 2.8Å. The structure analysis is in progress.

This work is a part of the "Structurome Project" that aims at structure determination of all the proteome components of T. thermophilus HB8 at SPring-8, Harima Institute of RIKEN.

P11.04.081 CRYSTAL STRUCTURE OF HYDROXYLAMINE OXYDOREDUCTASE IN AN ORTHORHOMBIC FORM. N. Igarashi, Institute of Materials Structure Science, High Energy Accelerator Research Organization, Tsukuba, 305-0801, Japan, K. Hiraishi and N. Tanaka, Faculty of Bioscience and Biotechnology, Tokyo Institute of Technology, Yokohama, 226-8501, Japan

We have solved the X-ray crystal structure of hydoxylamine oxidoreductase (HAO) from an autotrophic bacterium *Nitrosomonas europaea* obtains [1]. HAO catalyzes the oxidation of hydroxylamine to nitrite. The enzyme has a molecular mass of 200 kDa with 24 hemes which participate in catalytic function and electron transport. The crystal structure revealed the peculiar heme assembly and the “dielectron transfer” mechanism. However, the complete molecular structure still remains unsolved because of the crystal packing. In order to determine the entire three-dimensional structure of HAO, we have carried out the X-ray studies on this enzyme in another crystal form.

In our previous paper [1], obtained crystals were hexagonal space group $P6_3$ with unit cell dimensions of a=b=96.2Å, c=265.6Å and with two subunits per asymmetric unit. After screening for crystallization, new crystals suitable for the X-ray diffraction experiment were acquired by equilibration of HAO solution (20 mg/ml) against 17% (w/v) PEG4000 in 50mM potassium phosphate buffer (pH6.5). HAO crystallized in the orthorhombic space group $P2_12_12_1$ with unit cell dimensions of a=126.4Å, b=171.7Å, c=100.5Å and with one trimer molecule per asymmetric unit. Intensity data were collected up to 3.5Å resolution at BL6A in the Photon Factory.

Molecular replacement using the coordinates of HAO subunit has been successful and the current R-factor is 22%. The overall molecular assembly is the same as the one in the hexagonal crystal form. Further refinement is in progress. Structural details and comparison between the different crystal forms of HAO will be presented.

P11.04.082 THREE-DIMENSIONAL STRUCTURE OF THE REDUCED FORM OF A NINE HAEM CYTOCHROME C AT PH 7.5 AND PH 9.5 I. Bento, P. M. Matias, R. Coelho and M. A. Carrondo, ITQB-UNL, P. O. Box 127, P-2780 Oeiras, Portugal

The nine haem cytochrome c has been isolated form Desulfovibrio desulfuricans ATCC 27774 cells grown under both nitrate and sulfate respiring-conditions [1]. Its physiological function is not yet known, but it is believed to be part of the periplasmic assembly of proteins involved in recycling the molecular hydrogen release by the cells as a result of the lactate metabolisation [2]. Nine haem cytochrome c is a monomer of 37.8 kDa, with 292 residues and nine heam groups colvalently bound to the polypeptidic chain [2,3]. Reduced crystals were obtained by adding sodium dithionite to the oxidized crystals, grown as described by Matias et. al. (1999), after transfering them to a set of new crystallization drops at different pH values. Two data sets, from two crystals reduced at different pH values (7.5 and 9.5) were collected at ESRF (BM-14 and EH-3) in Grenoble. The first data set showed a resolution of 2.0Å and the second a resolution of 1.8Å. Both crystals belong to the monoclinic space group with two molecules in the asymmetric unit. In this presentation we report the results of the structure refinement of the two reduced forms at pH 7.5 and 9.5. Also, the differences found will be discussed.

P11.04.083 STRUCTURE - FUNCTION RELATIONSHIPS IN BOTULINUM NEUROTOXIN TYPE B. S. Swaminathan, S. Eswaramoorthy, & J. Hartling, Biology Department, Brookhaven National Laboratory, Upton, NY 11973, USA

Clostridial neurotoxins belong to the class of AB toxins with separate domains for activity and binding. Botulinum and tetanus neurotoxins cause neuroparalytic syndromes of botulism and tetanus, which are characterized by serious neurological disorders. These toxins are among the most poisonous, with their

LD_{50} in humans in the range of 0.1 - 1 ng per kg. Of the seven serotypes, A to G (BoNT, EC 3.4.24.69), produced by *Clostridia botulinum,* only BoNT/A, B and E have been implicated in cases of botulism in humans. These toxins produced as a single chain of 150 kDa are cleaved by an endo protease before being released into a heavy chain of 100 kDa and a light chain of 50 kDa held together by a single disulfide bond. Except for BoNT/E, other botulinum neurotoxins are released as di-chains which are multifold more poisonous than single-chain toxins. BoNTs block the release of acetylcholine at the neuromuscular junction causing flaccid paralysis. The presence of a conserved zinc binding motif HEXXH in the middle of the light chain has led to the discovery that these toxins are zinc endopeptidases acting specifically on protein components of the same neuroexocytosis apparatus present in cytosol.

BoNT/B has been crystallized in the space group $P2_1$ with unit cell dimensions a = 78.16, b = 125.56, c = 94.26 Å and β = 112.46° with two molecules per unit cell. These crystals diffract at least to 2.0 Å resolution. Native and derivative data have been collected at the National Synchrotron Light Source, Brookhaven National Laboratory. The crystal structure has been determined by a combination of MIR and MAD methods. Results from the structural analysis and the functional relationships of the three distinct domains observed in the crystal structure will be discussed.

Research supported by the Office of Non-proliferation and National Security of the U.S. Department of Energy under prime contract No. DE-AC02-98CH10886 with Brookhaven National Laboratory.

P11.04.084 TOWARDS THE CRYSTAL STRUCTURE DETERMINATION OF GLYCEROL DEHYDROGENASE FROM THERMOTOGA MARITIMA. Vasundara Srinivasan, Kesen Ma, J. P. Rose, Michael W. W. Adams and B.-C. Wang, Department of Biochemistry and Molecular Biology, University of Georgia, Athens, GA 30602, U.S.A.

Glycerol dehydrogenases catalyze the reversible reaction of glycerol to glyceraldehyde. This enzyme has been isolated from several organisms. One of the most thermostable is from Thermotoga Maritima, which is an anaerobic, hyperthermophilic organism growing optimally at 80°C.

Glycerol dehydrogenase from Thermotoga is a tetramer with a subunit molecular weight of 45 kDa. The isolated enzyme contains both 'Fe' and 'Zn' and is NAD dependent. This enzyme has been crystallized by hanging drop vapor diffusion method using 2-Methyl -2,4-pentane diol as the precipitant. The crystals diffracted to a resolution of 1.4Å at the EMBL Hamburg Synchrotron source and belong to the space group I422 with cell dimensions of a =105.2 Å, c = 134.4 Å. Heavy atom derivative data using Pt has also been collected to a resolution of 2.3 Å and the structure solution is in progress.

Elucidation of the structure will give an insight into the thermostability and metal binding characteristics of the enzyme. It will also enable comparisons to be made with other classes of enzymes.

P11.04.085 CRYSTALLOGRAPHIC STUDY OF HEMOGLOBIN FROM THE GREEN ALGA *C.EUGAMETOS*. Pesce, A. Advanced Biotechnology Center and Department of Physics-INFM, University of Genova, Italy, and Couture, M. and Guertin, M., Department of Biochemistry, Laval University, Quebec-Canada, and Ascenzi, P., Department of Biology, Third University of Roma, Italy, and Bolognesi, M. Advanced Biotechnology Center and Department of Physics-INFM, University of Genova, Italy.

Besides the universal occurrence of hemoglobin (Hb) in vertebrates, heme-based oxygen carriers are widespread also in invertebrates, plants, fungi, protozoa and bacteria. This discovery has brought about unexpected views on the functional properties and structural organization in this protein homology family.

Here we present our current work and results on the crystallographic analysis of hemoglobin from the unicellular green alga *C.eugametos*. In this alga, a Hb (Chlamy_Hb) is expressed in response to visible light: this constitutes the first evidence for the presence of Hb in chloroplasts. Chlamy_Hb was expressed as the H19 mutant (121 amino acid residues), bearing shortened N-terminal helix. Very thin and small crystals have been grown in a week and a native data set has been collected at ESRF in Grenoble, at 1.53 Å resolution. The crystals belog to space group $P2_12_12_1$ (unit cell: a = 34.6 Å, b = 53.1 Å, c = 67.2 Å, one molecule per asymmetric unit).

Due to low sequence homology with known Hb structures, it was not possible to solve the structure via Molecular Replacement.

Up to now, we have found phase information with the MIR method, using an uranyl-acetate and a potassium-tetrachloroplatinate derivative (data sets collected in house, 16-3.1 Å resolution). Two sites were found for uranium and one for platinum. Heavy atom refinement and phase extraction was performed by Phases, to 3.1 Å resolution. Map quality was improved using Sharp, and at this stage the map is good enough to build part of the model, using O.

P11.04.086 STRUCTURAL STUDIES OF DERIVATIVES OF COPPER-CONTAINING AMINE OXIDASE FROM ARTHROBACTER GLOBIFORMIS. Hiroshi Yamaguchi, Misa Kim, Takeshi Hiromoto, Takeshi Narita and Megumi Yoshimura, School of Science, Kwansei Gakuin University, Nishinomiya, Hyogo 662-8501, Japan, Hideyuki Matsunami and Katsuyuki Tanizawa, Institute of Scientific and Industrial Research, Ibaraki, Osaka 567-0047, Japan

Copper-containing amine oxidase (EC 1.4.3.6) catalyzes the oxidative deamination of various biogenic primary amines to the corresponding aldehydes, ammonia and hydrogen peroxide. The enzyme also contains a covalently bound organic cofactor, 2,4,5-trihydroxyphenylalanyl (topa) quinone, which is formed by the post translation of tyrosine residue in the presence of Cu^{2+} and oxygen molecule. To elucidate the mechanism of the topa quinone formation, we are studying structures of various derivatives of phenylethylamine oxidase from Arthrobacter globiformis (AGAO). Each subunit of the dimeric enzyme has a molecular size of about 70kDa and consists of 638 amino acid residues.

Wild-type and several mutants of AGAO were purified in the copper/topa quinone-less precursor form (apoenzyme), which contains the precursor tyrosine residue in an unmodified state. Crystals of apoenzyme bound with Ni^{2+} and with Co^{2+} at the copper site were obtained by both of the cocrystallization and soaking methods using the corresponding metal ions. Crystals of several mutant enzymes were also obtained. All crystals are isomorphous and belong to the space group C2 with cell dimensions about a=158Å, b=64Å, c=93Å and β=112°. Diffraction data of these crystals were collected on imaging plate diffractometers installed in rotating anode X-ray generator in house and at the station BL44B2 of SPring8, and on a large Weissenberg camera at the station BL18b of the Photon Factory. Structures of these crystals were refined by using a program XPLOR. These structures will be reported and the mechanism of post-translational formation of the topa quinone cofactor in AGAO will be discussed on the bases of those structures.

P11.04.087 CRYSTAL STRUCTURE OF THE VANADIUM DEPENDENT HALOPEROXIDASE FROM C. OFFICINALIS. M.N.Isupov, A.R.Dalby, A.A.Brindley, J.A.Littlechild Departments of Chemistry and Biological Sciences, University of Exeter, Stocker Road, Exeter, EX4 4QD, UK.

The crystal structure of the Corallina officinalis vanadium bromoperoxidase has been determined by single isomorphous replacement and refined at 2.3Å resolution to an R-factor of 18% (R-free 23%). The enzyme consists of 598 amino-acid residues folded into a single a -helical domain. The centre of this domain is formed by a four helix bundle, at the end of which the active site is located. Two bromoperoxidase subunits interact to form a tight dimer. The arrangement of subunits in the dodecamer has 23 point symmetry. At the centre of the dodecamer is a spherical cavity made up of the N-terminal helix from each of the twelve subunits.

A comparison of the three-dimensional structures of the Cor. officinalis bromoperoxidase and the chloroperoxidase from the fungus Curvularia inaequalis reveals similarities in their active sites. A monomer of the fungal enzyme can be structurally aligned with a dimer of the algal enzyme. This would suggest that the two enzymes share a common ancestor. The differing halogen specificity between the two enzymes appears to be controlled by the electrostatics within the vanadium-binding active site.

Brindley, A.A., Dalby, A.R., Isupov, M.N. and Littlechild, J.A. (1998) Acta Cryst. D54 p454-457.

P11.04.088 MOLECULAR EVOLUTIONARY ASPECTS OF PLASTOCYANINS BASED ON CRYSTAL STRUCTURES N. Okazaki†, T. Inoue†, N. Shibata†, H. Sugawara†, M. Gotowda†, S. Hamanaka†, T. Kohzuma§, F. Yoshizaki‡, and Y. Kai† †Dept. of Materials Chemistry, Osaka University, Osaka 565-0871, JAPAN, §Dept. of Chemistry, Faculty of Science, Ibaraki University, Ibaraki 310-0000, JAPAN, ‡Dept. of Biology, Faculty of Science, Toho University, Chiba 274-8510, JAPAN.

Plastocyanin is a small (91-105 amino acids) copper-binding protein, which functions as an electron transfer shuttle from cytochrome *f* of the b_6/f complex to $P700^+$ of Photosystem I in chloroplasts of algae and higher plants, and also in many cyanobacteria. We have determined the structures of plastocyanins from higher plant *silene*, green alga, *Ulva pertusa*, fern *Dryopteris crassirhizoma*, and cyanobacterium *Synechococcus* sp. PCC7942 at high resolution. Plastocyanins have a half-turn helix between two β-sheets at position 52 to 55 in eucaryotic plastocyanins. However, the conserved residue of Gly49 is changed to Ala49 in the fern plastocyanin, in which a three-turn helix is formed. The copper structures as well as the backbone structures of four plastocyanins are quite similar with that of poplar plastocyanin in spite of the sequence divergence among plastocyanins from cyanobacteria, algae and higher plants. However, the surface structures are strikingly different with each other. The negative charged acidic patch around Tyr83, which is thought to be important for docking with physiological redox partners, located on the east side of the molecule. The cyanobacteria and fern plastocyanins have only two acidic residues around Tyr83, and those are neutralized by basic residues. However, the latter plastocyanin possesses two acidic clusters at position 59-61 and 65-67. On the other hand, in all plastocyanins from higher plant the acidic clusters locate at position 42-44 and 59 to 61, while in all plastocyanins from green algae residues 58 and 59 are deleted. As the result, the charge distribution is quite different with each other, and these findings may provide new insights into the molecular evolutionary aspects of plastocyanins.

P11.04.089 CRYSTALS OF FAB+hCG COMPLEX AND FABS. M.A. Dingwall and N. W. Isaacs. Department of Chemistry, Joseph Black Building, University of Glasgow, G12 8QQ, U. K.

hCG, M_W ~40kDa, is a member of the family of Glycoprotein Hormones which includes Luteinizing Hormone, Follicle Stimulating Hormone, and Thyroid Stimulating Hormone. All are glycosylated and have cystine knot growth factor fold. The holo-hormone consists of α and β subunits which are species specific. The 92 residue α-subunit is identical but the β-subunit varies in size and sequence according to the hormone. The β-subunit defines biological specificity. The holo-hormone is required for function. hCG is the only placental member of the Glycoprotein Hormone family, and is essential for maintainence of early pregnancy.

Monoclonal antibodies(mabs), M_W ~150kDa, against hCG are used in the early detection of pregnancy, design of antifertility vaccines, in the detection of certain cancers, and investigations of receptor binding. Fragment antibodies (Fab) have been prepared by papain digestion.

Crystals of hCG+FabB111 and hCG+A113 complexes show weak diffraction. FabB111 and FabINN-hCG-53 (Fab53) crystals have been grown. Antibody B111 is directed against the C-terminal region of the β-subunit. Diffraction data has been collected to 2.8Å for the FabB111 on a MAC Science 2020 Image Plate at room temperature. The structure has been solved by molecular replacement using AMoRe [1], and refinement is in progress. Antibody INN-hCG-53 is directed against c1/c2 epitope that involves residues from both subunits of the hormone. A crystal of Fab53 has shown diffraction to 2.8Å at the synchrotron radiation source, Station 9.6, Daresbury, at room temperature.

(1) Narvaza. J. 1994. Acta Cryst. A50, 157-163.

P11.04.090 CAMELID SINGLE-DOMAIN ANTIBODIES: MORE NEW FEATURES. Decanniere, K., Desmyter, A., Lauwereys, M., Muyldermans, S. & Wyns, L. Vlaams Instituut voor Biotechnologie, Vrije Universiteit Brussel, Paardenstraat 65, B-1640 St. Genesius Rode.

In addition to normal antibodies, the serum of camelidae contains antibodies consisting of heavy chains only. These antibodies bind with high affinity and high specificity, and they are a fully functional part of the immune system. A substantial part of single-chain antibodies have competitive enzyme inhibiting capacity. The structure of the variable domain (VHH) cAb-Lys3 in complex with its antigen lysozyme shows how this can be achieved: part of the 24 amino acid long CDR3-loop of cAb-Lys3 inserts into the active site cleft of lysozyme, blocking it for the substrate. The remaining residues of the CDR3-loop are used to cover the VL-interface.

Recently, the structure of the VHH cAb-RN05 with its antigen RNase A showed high-affinity binding of an antibody using only two CDR-loops. A considerable number of the interactions involve main chain atoms from either the antibody or the antigen. Although cAb-RN05 has a “short” 11 amino acid CDR3-loop, it also folds back over the VL-side, making the protein less hydrophobic.

The analysis of the cAb-RN05 structure also confirmed an observation made for cAb-Lys3: the H1 and the H2-loop of both antibodies deviate from the known canonical structures. We therefore question the general validity of the canonical structures.

Currently, the structure of cAb-CA05 with specificity for carbonic anhydrase is under analysis. This antibody could be crystallized both as free antibody and in complex with the antigen. Preliminary results show yet another mode of binding, involving only the CDR3-loop.

The wide variety of binding modes revealed by only 3 structures make the VHH-domains of single-chain antibodies an interesting model system for protein-protein interactions.

P11.04.091 CRYSTAL STRUCTURE OF THE HUMAN P58 KILLER CELL INHIBITORY RECEPTOR (KIR2DL3, NKAT2). Katsumi Maenaka , Nathan Zaccai, Taeko Maenaka, David I. Stuart, and E. Yvonne Jones, Laboratory of Molecular Biophysics, Rex Richards Building, South Parks Road, Oxford OX1 3QU U.K. and Takeo Juji, Japanese Red Cross Central Blood Centre, Hiro-o, Shibuya-ku, Tokyo 120 Japan.

Human killer cell inhibitory receptors (KIRs), which belong to the immunoglobulin (Ig) superfamily, inhibit or activate the cytotoxic activity of natural killer (NK) cells by specific binding to MHC class I molecules on the target cell.

The extracellular region of the human p58 KIR specific for HLA-Cw3 related MHC class I (KIR2DL3, NKAT2) was produced and crystallised in 9-10% PEG8000, 50mM HEPES, 8% ethylene glycol, 0.5% octyl-β-glucoside, pH7.5, at 294K [1]. The crystal structure of KIR2DL3 has been solved at 3Å resolution. The structure shows the predicted topology of two tandem Ig-like domains but comparison with the previously reported structure of KIR2DL1 specific for HLA-Cw4 [2] reveals an unexpected change of 23° in the relative orientation of these domains. The altered orientation maintains the unusually acute inter-domain elbow angle, which therefore appears to be a distinctive feature of the KIRs. The putative MHC class I binding site which is located on the outer surface of the elbow, spanning both domains, can be modulated by differences in the relative domain orientations. This observation has implications for the general mechanism of KIR/MHC Class I complex formation.

P11.04.092 CRYSTAL STRUCTURE OF CD2-BINDING DOMAIN OF CD58. Shinji Ikemizu, Karl Harlos, David I. Stuart, E. Yvonne Jones, Laboratory of Molecular Biophysics, Rex Richards Building, South Parks Road, Oxford OX1 3QU UK and Simon J. Davis, Molecular Sciences Division, Nuffield Department of Clinical Medicine, John Radcliffe Hospital, Oxford, OX3 9DU, U.K.

The crystal structure of a CD2-binding chimeric form of CD58, solved to 1.8Å resolution [1], reveals that the ligand binding domain of CD58 has the expected IgSF V-set topology and shares several of the hitherto unique structural features of CD2, underlining their close evolutionary relationship. The chimeric protein

The chimeric protein was expressed in CHO cells and deglycosylated with endo H. Crystals grew in the presence of 1.1-1.5M ammonium sulphate, 50 mM Tris pH 8. Diffraction data were collected in-house at 297K and on BM14 of the ESRF at 100K to resolution of 3.0Å and 1.8Å respectively. The structure was determined by molecular replacement using the program AmoRe with the rat CD2 [2] as a search model. Initially, an unambiguous solution was found and a model was built using those diffraction data to 3.0Å. Subsequently, the model was refined and the phases extended to 1.8Å using data collected at ESRF. The current R and Rfree are 0.202 and 0.243, respectively. The refined atomic model comprises residues 1 to 171 of the chimera, 3 N-linked GlcNAc carbohydrates and 197 ordered water molecules.

P11.04.093 THE STRUCTURE OF CALCIUM-DEPLETED HUMAN C-REACTIVE PROTEIN FROM PERFECTLY TWINNED CRYSTALS. Mohamed A.M. Ramadan, Annette K. Shrive and Trevor J. Greenhough, School of Life Sciences, Keele University, Staffs ST5 5BG, UK, and John E. Volanakis and Larry J. DeLucas, University of Alabama at Birmingham, Birmingham, Alabama 35294 USA.

Human C-reactive protein (CRP) is the classical acute-phase reactant produced in response to tissue damage and inflammation, and is used almost universally as a clinical indicator of infection and inflammation. CRP and serum amyloid P component (SAP) are members of the pentraxin family of oligomeric serum proteins which has been conserved through evolution, homologues having been found in every species in which they have been sought.

While the Ca-dependent ligand-binding specificity of CRP for phosphocholine moieties has long been recognised, the ligand-binding and functional properties of Ca-depleted CRP remain the subject of some debate. In order to clarify the conformational changes which accompany calcium binding, the structure of Ca-depleted human CRP has been determined by X-ray crystallography.

Crystals of calcium-depleted human CRP are invariably twinned and those suitable for analysis are merohedral type II twins of point group 4 single crystals. Although R_{symm} values clearly indicate point group 422, the 50/50 twinning is revealed by the intensity statistics. The structure has been solved by molecular replacement using the Ca-bound human CRP structure [1], revealing two independent pentamers which form a face to face decamer across the twinning 422 2-fold axis. Cycles of intensity deconvolution, density modification (10-fold ncs) and model building (*O*), eventually including refinement (*X-PLOR*), give a final R-factor of 0.19 (R-free = 0.20). The structural changes which accompany calcium binding, and their implications for ligand, C1q and receptor-binding, will be discussed.

P11.04.094 STRUCTURE OF A SCAVENGER RECEPTOR CYSTEINE-RICH DOMAIN SHEDS LIGHT ON AN ANCIENT SUPERFAMILY. E. Hohenester, T. Sasaki and R. Timpl, Biophysics Section, Blackett Laboratory, Imperial College, Prince Consort Road, London SW7 2BZ, UK, and Max-Planck-Institut für Biochemie, D-82152 Martinsried, Germany.

Scavenger receptor cysteine-rich (SR) domains are found widely in cell surface molecules and some secreted molecules of the immune system, with about 3% of all known leukocyte receptor molecules containing SR domains [1]. The SR domain is evolutionarily ancient: SR domains in marine sponges and sea urchins are ≈30% identical to human homologues. The biological functions of SR domains are generally not well understood, but in some proteins they have been shown to mediate protein-protein interactions and ligand binding. We have determined the 2.0 Å crystal structure of the single SR domain (≈110 residues) of human Mac-2 binding protein, a tumour-associated antigen and extracellular matrix protein. The first structure of an SR domain reveals a novel fold composed of a six-stranded β-sheet cradling an α-helix. Sequence alignment demonstrates that the structure is a valid template for the entire SR superfamily. This allows a structural interpretation of previous mutagenesis data on ligand binding by the lymphocyte receptor CD6. The SR domain structure also reveals a curious close structural similarity to certain toxins. The pattern of disulfide bridges is completely unrelated, however, arguing against an evolutionary relationship.

P11.04.095 THE CRYSTAL STRUCTURE OF MRP8, A MEMBER OF S100 CALCIUM-BINDING PROTEIN FAMILY, AT 1.9 Å RESOLUTION. A.Nakagawa, K.Ishikawa and I.Tanaka, Division of Biological Sciences, Graduate School of Science, Hokkaido University, Sapporo 060-0810, Japan, and J.Nishihira, Central Research Institute, Hokkaido University, Sapporo 060-8638, Japan.

MRP8 (macrophage migration inhibitory factor-related protein 8) is a calcium-binding protein belonging to the family of S100 proteins, which is mostly expressed in myeloid cells and monocytes in events of acute and chronic inflammation. This protein was identified together with MRP14 in the synovial fluid of rheumatoid arthritis; MRP8 and MRP14 are reported to be involved in various biological events such as cytoskeltal-membrane interactions, regulation of cellular differentiation and cell-cycle progression beyond inflammatory reaction. MRP8 possesses two calcium-binding EF-hands shown by biochemical studies; however, its three dimensional structure has not been reported. In this study, we attempted to solve the three dimensional structure of MRP8 in a complex with Ca^{2+} by X-ray crystallography.

The structure of human MRP8 in a complex with Ca^{2+} was determined at 1.9 Å resolution by X-ray crystallography. The structure was initially solved by MAD phasing of ytterbium(Yb)-substituted crystal. MRP8 monomer consists of two helix-loop-helix (EF-hand) motifs that are joined by a 8-residues linker, and each EF-hand binds one Ca^{2+}. The MRP8 dimer is formed by non-covalent interactions between large hydrophobic patches of the two monomers that are related by a non-crystallographic two-fold symmetry.

In the Yb-substituted structure, Ca^{2+} bound to the C-terminal EF-hand was substituted Yb^{3+}, whereas the N-terminal EF-hand was not. The differential affinity of these two EF-hands to Ca^{2+} may affect the protein conformation of MRP8, which may induce variable forms of the complex with MRP8 homodimer or heterodimer with MRP14.

P11.04.096 CRYSTAL STRUCTURE OF HUMAN D-DOPACHROME TAUTOMERASE AT 1.54Å RESOLUTION. Hiroshi Sugimoto, Masae Taniguchi, Atsushi Nakagawa, Isao Tanaka, Division of Biological Sciences, Graduate School of Science, Hokkaido University, Sapporo 060-0810, Japan, and Masaki Suzuki and Jun Nishihira, Central Research Institute, School of Medicine, Hokkaido University, Sapporo 060-0815, Japan

D-dopachrome tautomerase (DDT) shows a low sequence homology (33%) with the macrophage migration inhibitory factor (MIF) and possesses similar tautomerase activity as well. Recent studies have identified MIF as pituitary hormone and immunoregulator. Therefore, interest in the structure-function relationship between DDT and MIF has increased as regards inflammation and immune responses. The diffraction data of human DDT were collected at the Photon Factory and the initial model was obtained by molecular replacement method. We refined the model, yielding an *R* factor of 0.164 and a free *R* factor of 0.192 in the resolution range of 20-1.54Å. The crystal structure shows cylindrical homotrimeric formation that has extensive contact between subunits by inter-subunit β-sheets. Its overall topology and trimeric formations are similar to human MIF. The Pro1 is located at the bottom of a positively charged pocket in which the conformations of Lys32 and Ser63 are highly conserved. A detailed comparison with human MIF, bacterial CHMI, and 4-OT structures revealed significant differences in the active site, the inter-subunit contacts and charge distribution on the molecular surface. It can be concluded that these features are related to the physiological role and tautomerase activity of MIF and DDT.

P11.04.097 CRYSTAL STRUCTURE OF THE SM3 ANTIBODY AGAINST POLYMORPHIC EPITHELIAL MUCIN MUC1 J.M. Lally[1], P. Dokurno[1], J. Taylor-Papadimitriou[2] and P.S. Freemont[1] [1] Molecular Structure and Function Laboratory, [2] Epithelial Cell Biology Laboratory, ICRF, PO Box 123, London, WC2A 3PX

The MUC1 epithelial mucin is a transmembrane glycoprotein with the extracellular domain made up largely of exact tandem repeats of 20 amino acids, each of which contains five potential glycosylation sites. Attention has been focused on this mucin as a tumour antigen because not only is it over-expressed in breast and other carcinomas, but it is aberrantly glycosylated making it antigenically distinct from the normally processed mucin. In breast tumours, the O-glycans which are added are shorter, resulting in the exposure of epitopes on the core protein which are normally masked. Several monoclonal antibodies recognising the core of the MUC1 repeat unit have been reported [1]. We have solved the structure of one of these antibodies, namely SM3 in complex with a 13-residue fragment of the MUC1 repeat [2]. We have also collected diffraction data from the SM3 antibody in complex with the 13-residue peptide containing the β-D-N-acetylgalactosamine (GalNAc) bound to the central threonine residue of the MUC1 core.The electron density map shows density consistent with the presence of a sugar residue attached to the central threonine. Such a modified peptide would be more akin to the natural state of the mucin on the carcinoma cell surface.

P11.04.098 GLYCOSYLATION AND FUNCTION? STRUCTURAL AND BIOLOGICAL CHARACTERISATION OF NONGLYCOSYLATED AND GLYCOSYLATED HBP. L.F. Iversen[1], P.B. Rasmussen[1], I.K. Larsen[2], H.J. Flodgaard[1] and J.S. Kastrup[2], [1]Novo Nordisk A/S, Novo Allé, DK-2880 Bagsvaerd, Denmark, [2]Dept. of Medicinal Chemistry, Royal Danish School of Pharmacy, Universitetsparken 2, DK-2100 Copenhagen, Denmark.

Previously, we have determined the structure of glycosylated heparin binding protein (HBP) [1] and elucidated the biological functions of HBP by the use of glycosylated protein (as it is found in vivo) [2]. HBP is strongly involved in host defence against infections. HBP is a chemoattractant for monocytes [3]. The three N-glycosylation sites of human HBP have been mutated to produce a nonglycosylated HBP (ng-HBP) mutant. ng-HBP has been crystallised and tested for biological activity. Complete X-ray data have been collected to 2.1 Å and the structure has been fully refined to an R-factor of 18.4%. The ng-HBP structure reveals that neither the secondary nor the tertiary structure have changed due to the removal of the glycosylation, compared to the glycosylated HBP structure. Although N-linked glycosylation occurs concomitant with polypeptide synthesis and therefore possesses the ability to influence early events in protein folding, we see no evidence of glycosylation influencing the structure of the protein. Also, the overall stability of ng-HBP seems to be unaffected as compared to glycosylated HBP as judged by the B-factors derived from the two X-ray structures. The flexibility of a glycosylation site might be determined by the local polypeptide sequence and structure rather than the specific glycosylation attached to a certain site The biological assay data indicate that ng-HBP has reduced potency as compared to its glycosylated counterpart, in that ng-HBP in combination with lipopolysaccharide (LPS), is less capable of stimulating monocytes cytokine release. The ability of ng-HBP to function as a LPS presenting protein towards the monocytes seems grately

affected by the removal of glycosylation. Protein fold, structure and stability are apparently similar for nonglycosylated and glycosylated HBP molecules, however the biological activity seems to be critically influenced by glycosylation.

P11.04.099 HUMAN HEPARIN BINDING PROTEIN: STRUCTURE AND FUNCTION OF TWO MUTANTS. A.K. Pedersen[1,2], L.F. Iversen[2], B.B. Stoffer[1], I.K. Larsen[1] and J.S. Kastrup[1]. [1]Department of Medicinal Chemistry, Royal Danish School of Pharmacy, Universitetsparken 2, 2100 Copenhagen, Denmark. [2]Novo Nordisk A/S, Novo Alle, 2880 Bagsværd, Denmark.

Heparin binding protein (HBP), also known as CAP37 or azurocidin, is a multifunctional protein with diverse and far reaching implications in host defence and inflammation. The antibiotic activity of HBP, directed against Gram-negative bacteria, was one of the first functions of HBP to be elucidated . HBP binds strongly to the lipid A component of endotoxin, and it has been suggested that the bactericidal effect of HBP is due to binding of lipid A [1].

HBP is an inactive serine protease homologue, and the inactivity is caused by selective mutations in the active-site triad (H41S and S175G). The human HBP exhibits 44 % sequence identity with human neutrophile elastase [2]. Despite the inactivity of HBP, the serine protease inhibitor BPTI (bovine pancreatic trypsin inhibitor) is still capable of binding to HBP [3].

HBP consists of 225 amino acid residues, possesses three putative N-glycosylation sites, and is highly glycosylated. Human HBP has been expressed in the baculovirus system as a 28 kDa protein, resulting in a glycosylation degree of 13 % [4]. The structure of native glycosylated HBP has been determined at 2.3 Å resolution at room temperature [1] and at 1.1 Å resolution at 120 K [5].

In order to identify amino acid residues of importance for lipid A and BPTI binding, respectively, two different mutants have been designed ([R23S,F25E]hHBP and [G175Q]hHBP). X-ray data have been collected to 2.5 Å and 1.9 Å, respectively, of the mutants. Structure determinations and refinements are in progress.

P11.04.100 STRUCTURAL STUDIES ON A N-TERMINALLY TRUNCATED C3d,g FRAGMENT OF THE COMPLEMENT SYSTEM. G. Zanotti, A. Bassetto, Dept. of Organic Chemistry and Biopolymer Research Center, U. of Padova, Padova, Italy, and M. Stoppini, Dept. of Biochemistry, U. of Pavia, Pavia, Italy and C. Folli, and R. Berni, Inst. of Biochemical Sciences, U. of Parma, Parma, Italy

The complement system is the primary humoral mediator of antigen-antibody reactions. It consists of at least 20 chemically and immunologically distinct plasma proteins capable of interacting with one another, with antibody, and with cell membranes. Following activation of the system, these interactions lead to the generation of biological activity which ranges from lysis of a spectrum of different kinds of cells, bacteria, and viruses to direct mediation of inflammatory processes.

Serum complement protein C3 plays a central role in both classical and alternative pathways of complement activation. The C3dg fragment, an activation product of C3, is involved in the amplification of antigen signal to B lymphocytes through the interaction with the B cell complement receptor CR2.

The C3dg fragment has been purified from rat plasma. A N-terminally truncated form of this fragment has been crystallised by vapour diffusion and diffraction data have been collected under cryogenic conditions by using the ELETTRA synchrotron source. Two crystal forms have been found: a) a tetragonal space group $P4_32_12$, with one molecule in the asymmetric unit and a resolution limit of 1.4 Å; b) an orthorhombic space group $P2_12_12_1$, with four molecules in the asymmetric unit and a resolution limit of 1.9 Å. The structure has been solved for both crystal forms, using the molecular replacement method, and refined. In both cases the C3d,g fragment presents a fold very similar to the C3d fragment [1] and a dimeric arrangement in the crystal.

[1] Nagar, B., Jones, R. G., Diefenbach, R. J.., Isenman, D. E. and Rini, J. M. Science 1998, 280, 1277-1281

P11.04.101 CRYSTAL STRUCTURE OF MHC CLASS II ASSOCIATED INVARIANT CHAIN FRAGMENT IN COMPLEX WITH CATHEPSIN L Gregor Guncar, Galina Pungercic, Ivica Klemencic, Vito Turk, Dusan Turk @ Department of Biochemistry and Molecular Biology, Josef Stefan Institute, Jamova 39, 1000 Ljubljana, Slovenia

Lysosomal cysteine proteases cathepsins S and L play crucial roles in degradation of invariant chain during maturation of MHC class II molecules and antigen processing. p41 form of invariant chain includes a fragment, which specifically inhibits cathepsin L but not S. The crystal structure of p41 fragment, a sequence homologue of the thyroglobulin type-1 domains, has been determined at 2.0 Å resolution in complex with cathepsin L. Structure of the p41 fragment has revealed a novel fold of cysteine protease inhibitors. It consists of two subdomains, each stabilized by disulfide bridges. The first subdomain is an α-helix - β-strand motif, whereas a β-strand arrangement is the predominant feature of the second subdomain. The wedge shape and three-loop arrangement of p41 fragment bound to the active site cleft of cathepsin L is reminiscent of the inhibitory edge of cystatins, and is the first observed example of convergent evolution in cysteine protease inhibitors. However, the different fold of the p41 fragment enables additional contacts with the top of the R-domain of the enzymes, which defines the specificity determining S2 and S1' substrate binding sites. This enables inhibitors based on the thyroglobulin type-1 domain fold, in contrast to the rather nonselective cystatins, to exhibit specificity for their target enzymes.

P11.04.102 STRUCTURAL BASIS FOR THE BINDING OF AN ANTI-CYTOCHROME C ANTIBODY TO ITS ANTIGEN. Shankari E. Mylvaganam [1,2], Yvonne Paterson [3] and Elizabeth D. Getzoff [1]. [1] The Scripps Research Institute, Dept. of Molecular Biology MB4, 10550 N. Torrey Pines Rd., La Jolla, CA 92037 USA, [2] Structural Bioinformatics, Inc., Dept. of Structural Sciences, 10929 Technology Place, San Diego, CA 92127 USA and [3] University of Pennsylvania, Dept. of Microbiology, PA 19104, USA.

The structural mechanism involved in the binding of the IgG_1 monoclonal antibody E8 to its highly charged protein antigen horse cytochrome *c* (cyt *c*) is revealed by the crystal structures of the antigen-binding fragment (Fab) of E8 bound to cyt *c* (FabE8-cyt*c*), determined to 1.8Å resolution, and of the uncomplexed Fab E8 (FabE8), determined to 2.26Å resolution. The antigen binds to the pre-formed V_L `hill' and $V_H$ `valley' shape of the grooved E8

paratope. The E8-cyt*c* association covers a buried surface area (1084Å^2) similar to that of other protein-antigen antibody interfaces, but is unique in that the E8 antibody uses V_L and V_H equally to bind its antigen. All six complementarity determining regions of E8 contact the antigen, covering three major discontiguous segements (33 to 39; 56 to 66; 96 to 104) and two minor sites on cyt *c*. This crystallographic definition of the E8 epitope complements and extends biochemical mapping and two-dimensional nuclear magnetic resonance with hydrogen-deuterium exchange studies. Local changes in atomic positions in both the cyt-*c* (of up to 9Å) and E8 (4Å) and 48 bound water molecules at the FabE8-cyt*c* interface facilitate antibody-antigen interactions. The antibody-antigen interactions include 13 hydrogen bonds, five ion pairs and 67 van der Waals contacts. Our comparative studies of FabE8-cyt*c* x-ray structure with the 1.8Å resolution x-ray structure of D1.3Fv-hen-egg-white lysozyme (HEL) complex reveal how the nearly identical V_L sequences of E8 and D1.3 antibodies bind to their respective antigens. Details of the antibody/antigen complementarity, conformational change, interactions and solvation will be presented.

P11.04.103 HIGH RESOLUTION CRYSTAL STRUCTURE OF FREE ANTIBODY HYHEL-63 AND COMPLEX WITH ITS ANTIGEN HEN EGG-WHITE LYSOZYME Hongmin Li[1], Yili Li[2], Sandra J. Smith-Gill[2] and Roy A. Mariuzza[1], [1]Center for Advanced Research in Biotechnology, University of Maryland Biotechnology Institute, 9600 Gudelsky Drive, Rockville, MD 20850 USA; [2]National Cancer Institute, National Institute of Health, Frederick, MD 21702-1201 USA

A detailed knowledge of the molecular basis of protein-protein recognition is an essential element in understanding protein function. Monoclonal antibodies specific to hen egg-white lysozyme have been studied extensively by X-ray crystallographic techniques, providing valuable information on the molecular architecture of protein-protein interactions. Here we report the high resolution crystal structure of the antigen binding fragment (Fab) of the monoclonal antibody HyHel-63, both free and bound to its protein antigen. HyHel-63 is an IgG2a(κ) antibody specific for hen egg-white lysozyme. The sequence of HyHel-63 is about 90% homologous to that of HyHel-10, a well characterized antibody specific for the same antigen. The affinity of HyHel-63 is lower than that of HyHel-10. Both the free Fab fragment and Fab complexed with lysozyme were crystallized in two crystal forms and four sets of X-ray diffraction data were collected to high resolution under cryo-conditions (for free Fab: space group C2: 2.0A; P1: 1.9Å; for the complex: space group $P4_22_12$: 2.0A; $P4_12_12$: 2.8Å). The epitope on hen egg-white lysozyme recognized by HyHel-63 is similar to that recognized by HyHel-10; however, some differences were observed between the two structures. A more detailed comparison of free and complexed Fab and of different crystal forms will be described.

P11.04.104 STRUCTURE OF THE SINGLE-CHAIN FV MFE-23: INTERMOLECULAR CONTACTS PROVIDE A MODEL FOR ANTIBODY-ANTIGEN INTERACTIONS M. K. Boehm[1,2], A. L. Corper[3], T. Wan[3], M. K. Sohi[3], B. J. Sutton[3], J. D. Thornton[2], P. A. Keep[2], K. A. Chester[2], R. H. J. Begent[2], S.J. Perkins[1] [1] Dept. Biochemistry and [2] Dept. Oncology, Royal Free Campus, Royal Free and UC Medical School, UCL, Rowland Hill St., London NW3 2PF, UK. [3] Randall Institute, King's College London, 26-29 Drury Lane, London WC2B 5RL, UK.

MFE-23 is an important murine filamentous phage-derived single-chain Fv antibody molecule which targets colorectal cancer through its specificity for carcinoembryonic antigen (CEA), a cell-surface member of the immunoglobulin superfamily. MFE-23 used in this study contains an N-terminal V_H domain joined by a $(Gly_4Ser)_3$ linker to a V_L domain (κ chain) with an 11-residue C-terminal myc-tag. The crystal structure was determined at 2.4 Å resolution by molecular replacement with an R_{cryst} of 19.0%. In the crystal lattice, two MFE-23 molecules were associated back-to-back, related by a crystallographic two-fold axis. Five of the six antigen-binding loops (*L1, L2, L3, H1, H2*) conformed to known canonical structures. The sixth loop *H3* was fitted to well-ordered electron density, and its structure was atypical of those previously described for H3 loops, being defined by a buried Thr-H100 residue. The antigen binding site displayed a large acidic region mainly located within *H2* and a large hydrophobic region within *H3*. A striking feature of the intermolecular packing within the crystal was a large region of contact and surface complementarity between the *H1*, *H2* and *H3* loops and the DEBA β-sheet of an adjacent molecule. These interactions involved salt bridges and hydrogen bonds, and the intermolecular contacts coincided with residues in *H1*, *H2* and *H3* that were predicted to be important for antigen contacts. A previously-described mutation that significantly perturbed MFE-23 binding to CEA corresponded to a *H3* residue that participates in these lattice contacts. It is concluded that these contacts may provide a model for antigen binding.

P11.04.105 LARGE PEPTIDE AND GLYCOPEPTIDE ANTIGEN PRESENTATION BY MHC CLASS I MOLECULES. Jeffrey A. Speir[1], James Stevens[2], Ussama M. Abdel Motal[3], Etienne Joly[2], Mikael Jondal[3], Kristen Fischer Lindahl[4], Geoff W. Butcher[2], and Ian A. Wilson[1], [1]The Scripps Research Institute, La Jolla CA USA, [2]The Babraham Institute, Babraham Cambridge UK, [3]Karolinska Institutet, Stockholm Sweden, [4]University of Texas Southwestern Medical Center, Dallas TX USA

Post-translationally modified peptides and peptides bulged from the MHC class I binding groove have the potential to alter T cell reactivity through hapten interactions with the TCR and altered exposed peptide conformations, respectively. We have determined the crystal structures of two representative MHC complexes having the largest and longest single peptides observed in MHC class I molecules. H-2Kb restricted glycopeptide RGY8-6h-Gal2 generates CTL expressing both a/b TCR, specific for glycopeptide, and g/d TCR, specific for the disaccharide. The 2.2A resolution crystal structure of Kb/RGY8-6h-Gal2 demonstrates the central region of the TCR footprint is dominated by the highly exposed carbohydrate and thus explains the generation of carbohydrate-specific T cell responses. Rat MHC class I RT1.Aa is believed to be the maternally-transmitted factor responsible for tissue graft rejection between rats expressing polymorphic forms of mitochondrial ATPase 6. Indeed, RT1.Aa complexed with a 13 residue peptide from ATPase 6 elicits full CTL activity in vitro and is the first rat CTL epitope and minor histocompatibility antigen identified at the molecular level. The preliminary crystal structure of RT1.Aa/13N3E reveals the N and C-termini of 13N3E are both anchored in the RT1.Aa binding groove and a distinct peptide conformation for each of the two molecules occupying the asymmetric unit. One conformation, free of crystal contacts, is bulged near the C-terminus highly exposing four of the peptide residues. The other conformation, influenced by crystal packing contacts, is in a completely different conformation in order to adapt to its new environment. Interestingly, the polymorphic residue of 13N3E remains highly exposed in either conformation. Together these complexes represent highly exposed MHC class I antigens that can readily change structure and therefore significantly alter the nature of the TCR-MHC interaction.

P11.04.106 THE CRYSTAL STRUCTURE OF HORSESHOE SHAPED HEMOLIN MONOMER: A NOVEL MECHANISM FOR HOMOPHILIC ADHESION? Xiao-Dong Su[1], Louis N. Gastinel[2], Pamela J. Bjorkman[3], [1]Department of Molecular Biophysics, Center for Chemistry and Chemical Engineering, P.O. Box 124, Lund University, S-221 00 Lund, Sweden, [2]AFMB, CNRS UPR 9039, 31 Chemin Joseph Aiguier, 13402 Marseille Cedex 20, France, [3]Division of Biology 156-29, and Howard Hughes Medical Institute, California Institute of Technology, Pasadena CA

Hemolin, an insect immunoglobulin superfamily member, is a lipopolysaccharide-binding immune protein induced during bacterial infection. The 3.1 Å crystal structure reveals a bound phosphate and patches of positive charge that may represent the lipopolysaccharide binding site, and a new and unexpected arrangement of four immunoglobulin-like domains forming a horseshoe. Sequence analysis and analytical ultracentrifugation suggest that the domain arrangement is a feature of the L1 family of neural cell adhesion molecules related to hemolin. These results are relevant to interpretation of human L1 mutations in neurological diseases, and suggest a domain swapping model for how L1 family proteins mediate homophilic adhesion.

P11.04.107 1.9Å STRUCTURE OF THERAPEUTIC ANTIBODY CAMPATH-1H Fab IN COMPLEX WITH A SYNTHETIC PEPTIDE ANTIGEN: A.C.Bloomer and L.C.James, MRC Laboratory of Molecular Biology, Hills Road, Cambridge CB2 2QH, UK and G.Hale & H.Waldmann, Sir William Dunn School of Pathology, South Parks Road, Oxford, OX1 3RE, UK

CAMPATH-1 antibodies have a long and successful history in the treatment of leukaemia, autoimmune disease and transplant rejection. The first antibody to undergo 'humanisation', CAMPATH-1H permits treatment with limited patient anti-globulin response. It recognises the CD52 antigen which is a small glycosylphosphatidylinositol(GPI)-anchored protein expressed on lymphocytes and it mediates cell depletion. We present the 1.9Å structure of Fab from CAMPATH-1H complexed with a peptide analogue of the antigenic determinant of CD52.

Analysis of the CAMPATH-1H binding site reveals features of the CDRs that contrast with most other known antibodies:
L3 plays a dominant role in antigen binding. H3 participates in only two main-chain interactions in CAMPATH-1H, although this loop is usually essential for effective antigen recognition.

The CAMPATH-1H binding site is highly basic; ionic interaction with the ethanolamine phosphate in the GPI anchor of CD52 has long been thought to be important in antigen binding. The structure reveals a number of important specific ionic interactions, including Lys53H but not Lys52bH as previously suggested. Prolonged treatment with CAMPATH-1H can lead to patient anti-idiotype responses which may be exacerbated by the unusually high number of basic residues in the antibody. This suggests that a strategy where redundant basic residues are replaced with neutral counterparts may be effective in further reducing the immunogenicity of this versatile and widely used antibody.

This CAMPATH-1H structure is guiding current antibody engineering in three important ways:

- rational design of a higher-affinity antibody
- removal of potentially immunogenic residues not affecting antigen-binding
- facilitating the design of non-binding mutants for use as tolerogens.

P11.04.108 THE STRUCTURE OF THE SUPERANTIGEN STAPHYLOCOCCAL ENTEROTOXIN H DETERMINED TO 1.7 Å RESOLUTION. M. Håkansson, K. Petersson, L. A. Svensson, Molecular Biophysics, Lund University, Box 124, 221 00 Lund, H. Nilsson, G. Forsberg, P. Björk, P. Antonsson, Active Biotech Research AB, Box 724, 220 07 Lund

Staphylococcal enterotoxin H (SEH) has been determined to 1.7 Å resolution using data from the crystallographic beamline, BL711, at the MAX-laboratory. It has the conventional superantigen fold; a β-grasp domain and a smaller β-barrel domain. Superantigens are molecules of biological interest, since they trigger the immunosystem by cross-linking T cell receptors (TcR) and MHC class II molecules in a more non-specific way than a normal antigen. SEH has a pI of 5.7 and exhibits a markedly negatively charged surface in a probable MHC class II binding region. The large deviations in both MHC and TcR binding regions implies substantial differences in receptor interactions compared to related superantigens. SEH was solved by molecular replacement technique making use of the SEA structure (Schad *et al*, 1995) as a model. SEA and SEH share 37 % sequence identity and the root mean square deviation of Cα between the structures are 2Å. At present the SEH model contains 210 amino acids, 100 water and four sulphate molecules. The R- and R_{free}-factors are 0.204 and 0.235, respectively.

Schad EM, Zaitseva I, Zaitsev VN, Dohlsten M, Kalland T, Schlievert PM, Ohlendorf DH, Svensson LA. 1995. Crystal structure of the superantigen staphylococcal enterotoxin type A. EMBO J 14: 3292-3301.

P11.04.109 THE 2.16 Å REFINED STRUCTURE OF 38-KDA PROTEIN ANTIGEN B (PAB) FROM *MYCOBACTERIUM TUBERCULOSIS*. Nand K. Vyas, Meenakshi N. vyas, Abha Choudhary and Florante A. Quiocho. Department of Biochemistry and Howard Husghes Medical Institute, Baylor College of Medicine, Houston, Tx-77030, USA

The World Health Organization (WHO) estimates that about one third of the world population is infected by mycobacteria of *M. tuberculosis complex*. Tuberculosis kills about 2 to 3 million people each year. The efficacy of BCG vaccine varies from 0 to 80% when tested in different population of the world. The multi-drug-resistant tuberculosis and the high susceptibility of tuberculosis in HIV/AIDS infected population are the major public health concerns according to the WHO. For rational design of diagnostic reagents and subunit vaccines, high resolution structures of several species-specific antigens are needed. Among well characterized secreted protein antigens, the 38 kDa protein antigen b (Pab) from *M. tuberculosis* is a species-specific immunodominant antigen. We have determined the X-ray structure of this antigen to understand its biological and immunological functions. We have previously demonstrated unequivocally that Pab is phosphate-binding protein, that, like its couterpart in gram-negative bacteria, is involved in active transport.

To determine the three-dimensional structure of Pab, a recombinant protein prepared in our laboratory, was used to obtain single crystals by vapour diffusion method. X-ray diffraction data from a orthorhombic single crystal (space group P2(1)2(1)2 and cell dimensions: a=125.38 Å, b= 71.27Å and c=73.43 Å) were collected to 2.16 Å resolution. An Initial Pab structure, two molecules (A and B) in the asymmetric unit, was determined by docking of the structure of *E. coli* phosphate-binding protein (PBP) in the 4.0 Å MIR electron density map. Refinement of the Pab structure at 2.5 Å resolution showed that the electron density for molecule B was weaker than the molecule A. At this stage R-factor was 0.27 and R-free was 0.37, which indicated a possible positional disorder in molecule B. We have

now determined two postions for molecule B in the asymmetric unit of cell and free-R is 0.27 and regular R-factor is 0.24 for the 2.16 Å resolution data. The refined structure has allowed us to determine antigen-phosphate interactions and mapping of the known B and T cell epitopes.

P11.04.110 STRUCTURE, FUNCTION AND EVOLUTION OF SERUM PENTRAXINS FROM INVERTEBRATES TO HUMANS. Trevor J. Greenhough, Annette K. Shrive, Mohamed A. Ramadan, Alison M. Metcalfe, Jamie R. Cartwright and Margaret Hopkins, School of Life Sciences, Keele University, Keele, Staffs ST5 5BG, UK

The serum pentraxins C-reactive protein (CRP) and amyloid P-component (SAP) are members of a conserved family of cyclic oligomeric Ca-binding proteins, homologues of which have been found in mammals, fish, amphibians and the phylogenetically ancient horseshoe crab *Limulus polyphemus*. In humans, CRP plays a pivotal and complex role in the immune response and is the classical acute-phase reactant produced in response to tissue damage and inflammation. SAP-like pentraxin homologues are circulating lectins. Humoral components, such as the pentraxins, which are directly implicated in non-specific host defence and innate immunity and which have been preserved over long evolutionary periods, provide an ideal basis for the study of the evolution of the immune system and of molecular phylogeny and protein evolution.

The sequence homology and conservation of the pentraxins, and of their ligand-binding specificities has long since been recognised and evidence from electron micrographs has suggested that the cyclic nature of protomer aggregation across species is generally conserved. A more detailed view of these structures at the x-ray level shows that while the protomer fold and a cyclic mode of aggregation are conserved, the number of protomers and their relative orientations within the cyclic, biologically functional oligomer show remarkable variations between species.

The crystal structures of pentraxins from four species ranging from an invertebrate to humans will be presented. The conservation and evolution of the pentraxins and their ligand-binding specificities, their relationship to lectins, and the resulting implications for the evolution of innate immunity, will be discussed in the light of this new structural evidence.

P11.04.111 CHLOROQUINE BINDS TO L-LACTATE DEHYDROGENASE IN THE MALARIAL PARASITE (*PLASMODIUM FALCIPARUM*. Jonathan A. Read, Kay W. Wilkinson, Rebecca Tranter, Richard B. Sessions & R.Leo Brady, Department of Biochemistry and Centre for Molecular Recognition, University of Bristol, Bristol BS8 1TD.

Although the molecular mechanism by which chloroquine exerts its effects on the malarial parasite *Plasmodium falciparum* remains unclear, the drug has previously been found to interact specifically with the glycolytic enzyme lactate dehydrogenase from the parasite. In this study we have determined the crystal structure of the complex between chloroquine and *Plasmodium falciparum* lactate dehydrogenase. The bound chloroquine is clearly seen within the NADH binding pocket of the enzyme, occupying a similar position to the adenyl ring of the cofactor. Chloroquine hence competes with NADH for binding to the enzyme, acting as a competitive inhibitor for this critical glycolytic enzyme. Specific interactions between the drug and amino acids unique to the malarial form of the enzyme suggest this binding is selective. Inhibition studies confirm that chloroquine acts as a weak inhibitor of lactate dehydrogenase, with mild selectivity for the parasite enzyme. As chloroquine has been shown to accumulate to millimolar concentrations within the food vacuole in the gut of the parasite, even low levels of chloroquine within the host blood may contribute to the biological efficacy of the drug and explain how specificity problems are not encountered. The structure of this enzyme-inhibitor complex provides a template from which the quinoline moiety might be modified to develop more efficient inhibitors of the enzyme.

P11.04.112 SINGLE POINT-MUTATION YIELDS 30-FOLD INCREASE IN BINDING AFFINITY OF A CARBOHYDRATE-SPECIFIC SCFV. Sonia I. Patenaude [1], Roula Thomas [1], C. Roger MacKenzie [2], N. Martin Young [2], Stephen V. Evans [1], [1] Department of Biochemistry, University of Ottawa, Ottawa K1H 8M5, Ontario, Canada, [2] Institute for Bioclogical Sciences, National Research Council of Canada, Ottawa K1A 0R6, Canada

The interactions between carbohydrate-specific antibodies and their antigens are typically of low affinity. Part of this weak binding lies in the fact that carbohydrate antigens are generally T-cell independant and cannot induce affinity maturation. Generation of mutant monoclonal antibodies with higher affinity for their carbohydrate antigens while maintaining the specificity of the wild-type antibody has proven challenging. We have used the three-dimensional crystal structure of an antibody scFv specific for the blood group A oligosaccharide antigen to design a number of site-directed mutants which show improved affinity while maintaining specificity. The higher affinities can be directly correlated with trends in amino acid mutations such as polarity, surface complementarity and side chain aliphatic character.

P11.04.113 INCOMPLETE MIMICRY OF THE RODENT BY A HUMANIZED FORM OF AN ANTI-γ-INTERFERON ANTIBODY. P.A. Ramsland, Z.-C. Fan, L.W. Guddat[†] and A.B. Edmundson. Oklahoma Medical Research Foundation, 825 NE 13th Street, Oklahoma City, OK 73104, USA. [†]Present address: Centre for Drug Design and Development, University of Queensland, St Lucia, Qld 4072, Australia.

The three-dimensional structures of "humanized" and mouse-human chimeric antigen-binding fragments (Fabs) of a murine anti-γ-interferon antibody have been determined by X-ray analyses at 2.9 Å resolution (Fan *et al*., J. Mol. Recognit. **12**:19-32). Comparison of these structures revealed that three of the four domains are nearly identical: V_L and C_L of the light (L) chains and C_H1 of the heavy (H) chains. However, the complementarity determining regions (CDRs) of the V_H domains do not resemble each other to the degree expected of loops with identical sequences. The substitution of serine for proline at position 7 allowed the N-terminal segment (designated 4-1) of the humanized V_H to be closely juxtaposed with the adjacent β strand (4-2). This tightening resulted in a decrease in space available for the last portion of the H chain framework region 1 (HFR1) and the first part of HCDR1, and led to the formation of an α-helix involving residues 25-32. In the humanized Fab, HCDR1, which is sandwiched between HCDR2 and HCDR3, modified the structures of both regions. HCDR2 was forced into a bent and twisted orientation both at the crown (around proline H52a) and the base of the loop. HCDR3 was also adjusted in shape and topography. In summary, the structural effects of humanization were (1) to increase the order of the HCDRs; (2) to confine the HCDRs into a smaller space; and (3) to change the directionality, accessibility and relative positions of side chains likely to serve as contacts in the binding of the γ–interferon antigen. Similarities in binding affinities of the two molecules can be rationalized by limited induced fit adjustments in their structures on antigen binding.

We thank, for supplying the antibodies, Protein Design Labs, Inc., Mountain View, CA 94043, USA.

P11.04.114 THE STRUCTURE AND MECHANISM OF THE BIOTIN BIOSYNTHETIC ENZYMES. D.Alexeev and L.Sawyer, Structural Biochemistry, ICMB, The University of Edinburgh, Michael Swann Building, King's Buildings, Mayfield Road, Edinburgh EH9 3JR, UK, and D.J.Campopiano, M.Alexeeva, S.P.Webster and R.L.Baxter, Edinburgh Centre for Protein Technology, The University of Edinburgh, Joseph Black Chemistry Building, West Mains Road, Edinburgh EH9 3JJ, UK.

Biotin is a vitamin synthesised only by bacteria and plants. They cannot use external biotin and have to rely on their own. We receive biotin from eating plants, and this makes the biotin biosynthetic pathway attractive for engineering the herbicides harmless to humans. Biotin is synthesised in four steps by four major enzymes: the products of the genes *bioF*, *bioA*, *bioD* and *bioB*. We have cloned, expressed and purified all four of them. Three enzymes have been crystallised: 8-amino-7-oxonanoate synthase (AONS, the product of the gene *bioF*), 7,8-diaminonanoate synthase (DANS from the gene *bioA*) and dethiobiotin synthetase (DTBS from *bioD*). We have solved the structures of AONS and DTBS and present the detailed study of their reaction mechanisms here.

DTBS is a unique ATP-dependent carboxylase that catalyses the insertion of CO, derived from carbon dioxide, in between the vicinal amino groups of the substrate, eventually resulting in formation of the *ureido* ring of dethiobiotin, the immediate precursor of biotin. We have examined by crystallography various trapped complexes of DTBS with substrates, products, reaction intermediates and their mimics. This information has been combined with kinetic measurements and site directed mutagenesis from which we propose the reaction mechanism and present a design for an inhibitor which targets the adenine binding site.

AONS belongs to the α-family of pyridoxal-5'-phosphate dependent enzymes. We present the structure of AONS in both the apo- and holo- forms, the structure of a reaction intermediate and the inhibited form of the enzyme. By analogy with related PLP-enzymes and using our spectroscopic, structural and mutational data, we have modelled the mechanism of AONS.

P11.04.116 NEW CRYSTAL FORM AND HIGH-RESOLUTION ANALYSIS OF PHOTO-REACTIVE NITRILE HYDRATASE IN THE ACTIVE FORM. Y. Kawano, N. Kamiya [1], N. Odaka, M. Yohda, I. Endo [2], [1] Division of Protein X-ray Crystal Analysis, RIKEN Harima Institute, The Institute of Physical and Chemical Research (RIKEN), Mikazuki-cho, Sayo-gun, Hyogo, 323-3, Japan. [2] Biochemical Systems Laboratory, The Institute of Physical and Chemical Research (RIKEN), Wako, Saitama 351-01, Japan.

Nitrile Hydratase (NHase) catalyzes the hydration of nitrile compounds to their corresponding amides and is used for the industrial production of acrylamide. NHase produced from Rhodococcus sp. N-771 consists of a- and b- subunits each with molecular weights of about 23k Da. The enzyme has a catalytic center of non-heme iron surrounded by a sequence of C109-X-L-C112-S-C114 in the a-subunit, which is highly consensus around NHases already known. The iron center is associated with an endogeneous nitric oxide (NO) in the inactive form, and the dissociation of NO molecule by irradiation of visible light leads the enzyme to the active form. The crystal structure of the inactive NHase has been analyzed at 1.7Å resolution by our group (Nature Struc. Biol. 5, 347-351 (1998)). This work clearly shows the NO molecule as a sixth ligand of the iron center. The NO molecule is stabilized by an unusual claw setting composed of three oxygen atoms of C112-sulfinic acids, hydroxyl group of S113 and C114-sulfenic acid. The two of three cystein residues in the consensus sequence of claw setting are post-translationally modified. The crystal structure of active NHase has also been analyzed by the other group (Structure 5, 691-699 (1997)). Unfortunately, however, the structure is only at a resolution of 2.6Å, which is insufficient for clarifying the claw setting structure in the active form. In order to realize much higher resolution analysis for the active NHase, we have searched a new crystal form. The new crystal obtained belongs to monoclinic system, space group C2 with cell dimensions of a=113.8Å, b=60.2Å, c=81.6Å, b=125.1º, and diffracts up to 1.5Å resolution. The high-resolution analysis of active enzyme will reveal conformational changes of the claw setting structure between the inactive and active NHases.

P11.04.117 STRUCTURAL ALLERGOLOGY: MAPPING B-CELL EPITOPES FROM CRYSTALLOGRAPHIC DATA. M. Gajhede, O. Mirza and A. Henriksen, Protein Structure Group, Department of Chemistry, Copenhagen University, Universitetsparken 5, DK-2100 Copenhagen, Denmark and H. Ipsen and M. D. Spangfort, Biochemical Allergy Research, ALK-Abelló, Bøge Alle 6-8, DK-2970 Hørsholm, Denmark.

The prevalence of allergic disorders has steadily increased in the Western world during the last decade and atopic individuals often show allergic reactions in response to protein allergens derived from pollens of trees and grasses, house dust and storage mites, animal dander and moulds. There are signs indicating that this increase is related to the general changes in the environment that has occurred during the later decades. Since allergy can have very severe symptoms or even be lethal, improved therapeutic tools (vaccines) is one of the large challenges of the next decade. One of the possible targets of a vaccine are the B-cell epitopes that can be identified using a combination of sequence alignments of related allergens and structure determination.

We have previously studied the conserved surface patches on the major allergen from birch pollen Bet v 1[1]. Here three patches on Bet v 1 was identified as common for the known major tree pollen allergens based on sequence alignment. Thus, any IgE recognizing these patches on Bet v 1 are prospective dominant epitopes and will be able to cross-react and bind to other Fagales major pollen allergens and give rise to allergic symptoms.

In order to confirm these results the two participants have done the crystal structure of a complex between Bet v 1 and the Fab fragment of a murine monoclonal antibody raised against Bet v 1 (BV16 Fab) (Mirza et al. submitted). The structure of the Bet v 1-BV16 Fab complex showed that the interaction surface was identical to one of the 3 predicted epitopes.

Recently we have done the structure of Ves v 5, a major allergen from the wasp venom (Henriksen et al. in preparation). Since there was not significant sequence similarity to any protein with known structure, the structure was solved by the MIR method to 1.9 Å resolution. An analysis of the structure and the B-cell epitopes will be presented.

P11.04.118 CRYSTAL STRUCTURE ANALYSIS OF FV FRAGMENT OF ANTIBODY (HYHEL10) COMPLEXED WITH HEN EGG LYSOZYME. H. Kondo, Bioscience and Chemistry Division, Hokkaido National Industrial Research Institute, Tsukisamu-Higashi 2-17, Toyohira, Sapporo 062-8517, Japan, K. Tsumoto, M. Shiroishi, Department of Biomolecular Engineering, Graduate School of Engineering, Tohoku University, Sendai 980-8579, Japan, M. Matsushima, Rational Drug Design Laboratories, Fukushima 960-1242, Japan, and I. Kumagai, Department of Biomolecular Engineering, Graduate School of Engineering, Tohoku University, Sendai 980-8579, Japan

In order to elucidate roles of non-covalent forces involved in antigen-antibody interactions in the structural aspects, we determined three-dimensional structure of Fv fragment of wild-type anti-hen egg white lysozyme (HEL) monoclonal antibody HyHEL10 complexed with HEL at 2.3Å resolution limit by molecular replacement method using HyHEL10 Fab fragment-HEL structure (Padlan *et al*., PDB code:3HFM) as a search model. In Fv-HEL complex, a salt bridge, which has not been observed in Fab-HEL complex, are found. In addition, some water molecules are found to locate in Fv-HEL interface, forming water-mediated hydrogen bonds between antigen and antibody. Furthermore, the area of the interface increases in about 10%. These structural changes are considered to compensate for unfavorable effect which is occurred by deletion of the constant regions of Fab, leading to the minimum decreased affinity of the antibody Fv fragment toward its antigen.

P11.04.119 CRYSTAL STRUCTURE OF S. CEREVISIAE UBC1 - CONFORMATIONAL FREEDOM IN A UBIQUITIN CONJUGATING ENZYME. R.S. Williams, R. Green, G. Garen, M.J. Ellison and J.N.M. Glover, Department of Biochemistry, University of Alberta, Edmonton, Alberta, T6G 2H7, Canada

The crystal structure of the core catalytic domain (aa 1-150) of Saccharomyces cerevisiae ubiquitin conjugating enzyme 1 has been determined at 1.9Å resolution. Ubc1(1-150) crystallized as a dimer and comparison of the two molecules in the monoclinic (p21) asymmetric unit reveal that Ubc1(1-150) can exist in distinct open and closed conformations. Regions conferring domain motion have been delineated through analysis of RMS phi-psi differences and alpha-carbon displacements of least-squared aligned coordinates for the two monomers. Comparisons with nuclear magnetic resonance dynamics data for human Ubc9 [1] indicate common regions of flexibility in Ubc core domains.

P11.04.120 CRYSTAL STRUCTURE OF A MAMMALIAN PURPLE ACID PHOSPHATASE WITH A μ-(HYDR)OXO BRIDGED DI-IRON CENTER. Eva H. Johansson[1] , Ylva Lindqvist[1], Helena Kaija[2], Pirkko Vihko[2] and Gunter Schneider[1], [1]Department of Medical Biochemistry and Biophysics, Karolinska Institutet, S-171 77 Stockholm, Sweden and [2]Biocenter Oulu and WHO Collaborating Centre for Research on Reproductive Health, University of Oulu, FIN-90220 Oulu, Finland

The crystal structure of purple acid phosphatase (PAP) from rat bone has been determined by molecular replacement and the structure has been refined to 2.2 Å resolution to an R-factor of 21.3 % (R-free 26.5 %). The core of the enzyme consists of two seven-stranded mixed β-sheets, with each sheet flanked by solvent-exposed α-helices on one side. The two sheets pack towards each other forming a β-sandwich. The di-iron center, located at the bottom of the active site pocket at one edge of the β-sandwich, contains a μ-hydroxo or μ-oxo bridge and both metal ions are observed in an almost perfect octahedral coordination geometry. The electron density map indicates that a μ-(hydr)oxo bridge is found in the metal center and that at least one solvent molecule is in the first coordination sphere of one of the metal ions.

The crystallographic study of rat PAP reveals that the mammalian enzymes are very similar in the overall structure to the plant enzymes in spite of 18 % overall sequence identity. In particular, coordination and geometry of the iron cluster is preserved in both enzymes and comparison of the active sites suggests a common mechanism for the mammalian and plant enzymes. However, significant differences are found in the architecture of the substrate binding pocket.

P12.04.001 HEMAGGLUTININ-NEURAMINIDASE FROM NEWCASTLE DISEASE VIRUS - THE CONTINUING SAGA. S.J. Crennell, A. Portner,[†] T. Takimoto,[†] and G.L.Taylor[‡]. School of Biology and Biochemistry, University of Bath, BA1 7RH, U.K.[†]St Judes Childrens Research Hospital, Memphis, TN, U.S.A. [‡]School of Biomedical Sciences, University of St. Andrews, KY16 9TS, U.K.

Hemagglutinin-Neuraminidase, (HN), one of the two surface proteins of paramyxoviruses, mediates the attachment of the virus to host cells and as such is a candidate for drug design not only against Newcastle disease (NDV), but also mumps and parainfluenza[1] whose HN share 33 and 25% sequence identity respectively with NDV HN.

HN was crystallised from 0.2M$(NH_4)_2SO_4$, 25%PEG4K and 0.1M acetate buffer pH4.6 in space group $P2_12_12_1$ with cell a≈73,b≈78 c≈200 Å. Native X-ray data have been collected to 1.98Å resolution on beamline X11 of the DESY synchrotron, Hamburg. HN has a predicted[2] structural similarity to influenza neuraminidase which shares 17% sequence identity but molecular replacement using the structures of influenza neuraminidases, bacterial neuraminidases or models based on these has been unsuccessful.

The crystals are very flexible, surviving abrupt changes of 3 pH points with severe lack of isomorphism being a major problem. 40 different native data sets and 165 derivative data sets at a variety of pH have cell dimensions varying by up to 16Å and have not yielded an isomorphous derivative. Multi-wavelength anomalous dispersion data collected on ESRF beamline BM14 from a Di-μ-iodobis(ethylene diamine)diplatinum(II) nitrate (PIP)-soaked crystal were processed with PHASES to give an overall figure of merit of 0.498 to 3.2Å. Phase extension has not yet given an interpretable map even when combined with in-house phased data sets in multi-crystal averaging.

P12.04.002 EXPRESSION AND PURIFICATION OF RECOMBINANT EBOLA VIRUS NUCLEOPROTEIN FOR CRYSTALLOGRAPHIC STUDIES. J.A. Potter and G. L. Taylor, University of Bath, Claverton Down, Bath, BA2 7AY, UK, and A. Fooks, CAMR, Porton Down, Salisbury, Wiltshire, SP4 OJG, UK.

The Ebola virus is an extremely virulent African haemorrhagic fever virus belonging to the *Filoviridae* family. The virions are composed of a central core formed by a ribonucleocapsid complex (RNP) which is surrounded by a lipid envelope derived from the host cell plasma membrane. The major structural RNP protein is the 83.3 kDa nucleoprotein (NP). The N-terminal 400 amino acids of NP show a high degree of homology within the filovirus family (1). This region, in common with other nonsegmented, negative strand RNA viruses, is hydrophobic. The less-conserved hydrophilic C-terminal half is highly acidic and may facilitate virion assembly by interacting with the matrix proteins or the putative second nucleoprotein, VP30.

Recombinant NP (cloned from Zaire subtype of Ebola virus) has been expressed as a histidine-tagged fusion protein in S*podoptera frugiperda* (Sf9) cells using the baculovirus expression system. The protein has an observed molecular weight of 104 kDa as determined by SDS PAGE and Western blots using both guinea-pig sera and anti-histidine monoclonal antibody. The

histidine-tagged protein will be purified by chromatography using resins charged with nickel ions. The purified sample will be used for crystallisation trials with the ultimate aim of deriving the atomic structure of NP using x-ray crystallography.

P12.04.003 TOWARDS THE STRUCTURE OF THE HERPES SIMPLEX VIRUS 1 SINGLE STRANDED DNA BINDING PROTEIN. Marina Mapelli, Hans van der Zandt and Paul Tucker, European Molecular Biology Laboratory, 69112 Heidelberg, DE.

ICP8 is the Herpes Simplex Virus 1 (HSV 1) single-stranded DNA-binding protein. It is a 128KDa nuclear zinc metalloprotein and participates in all the processes related to DNA replication, recombination and repair. It also has a function in the regulation of late gene expression. ICP8 binds ssDNA sequence non-specifically and cooperatively. The stoichiometry of binding falls in the range of 12 to 22 nucleotides, with a K_d of 0.2 mM and a cooperativity parameter ω of 38.

ICP8 is expressed in insect cells infected with a recombinant baculovirus. Purification is achieved by affinity and size exclusion chromatography. Despite the tendency to aggregation, it is possible to obtain a soluble and monomeric sample suitable for crystallization trials. The first ICP8 crystals grew by vapour diffusion in hanging drops as very thin plates. They exhibited poor (d_{min} = 7Å) and anisotropic diffraction.

Investigations were started in order to reduce the sources of structural or conformational microheterogeneities within the protein or between domains.

Limited proteolysis experiments in the presence and absence of ssDNA, suggested the existence of a 300 residue N-terminal domain not directly involved in DNA binding. The deletion mutant was produced but was found to be insoluble, probably indicating that a hydrophobic surface exists between domains. Genetic evidence supported by sequence analysis suggested that a 28 residue C-terminal tail, containing the nuclear localization signal, is likely to be unstructured and exposed. Therefore a mutant lacking 60 residues at the C-terminus was designed (ICP8ΔC). This mutant is soluble and monomeric and crystallizes under several conditions. Crystals are thicker, but retain a platy morphology. Nevertheless the diffraction pattern is greatly improved leading to a maximum resolution of 3.5Å. Recently two cysteines mapped on the N-terminal part of the protein, were identified as responsible for the cooperative nature of the binding [1], in agreement with the previous findings that cooperativity involves intermolecular contacts between free sulphidryl groups. We therefore decided to mutate the two cysteines to serines, to improve the protein stability and hopefully favour crystal growth. The new crystals look promising but their characterization is still at a preliminary stage.

P12.04.004 STRUCTURAL MODEL FOR THE RNA IN SATELLITE TOBACCO MOSAIC VIRUS. A. McPherson, S. B Larson, J. Day, A. Greenwood, and Yu. G. Kuznetsov. University of California, Irvine, Molecular Biology & Biochemistry, Irvine, CA 92697-3900.

The 1.8 Å structure of satellite tobacco mosaic virus (STMV) reveals approximately 50% of the genomic RNA organised as helical segments centred at icosahedral twofold axes, plus additional "free nucleotides". Proteolysis of 17 nm virions was shown by QELS to result in stable particles of 11 nm diameter which corresponds to the diameter of the RNA core. Amino terminal strands of protein subunits, the last twelve residues of which bear seven positive charges, appear to be included in the nucleic acid cores. Using QELS, it was shown that RNA cores remained condensed particles to about 75º C. Preparations of STMV, when examined by AFM, also showed some helicoid bodies of about 40-50 nm. which apparently reflect the structure of the RNA molecules when released from the virion. Low resolution difference Fourier analyses allowed us to delineate the paths of amino terminal strands which wrap tightly around the helical segments of RNA. An idealised model was constructed of the entire encapsidated RNA molecule based on the most efficient path of thirty helical stem–loop elements, connected by single stranded linkers, passing from dyad to dyad. The model consumes virtually all of the 1058 available nucleotides. Analysis of RNA base sequence in terms of secondary structure shows it is compatible with the model in that thirty stem–loop elements could indeed be expected to appear along the RNA. The predicted stems, based on Watson–Crick base pairing, vary in the number of base pairs, and have loops of variable sizes. Nonetheless, the array of stem–loop elements is a realistic variation on the idealized model, and is consistent with the RNA distribution observed by X-ray analysis.

P12.04.005 THE ROLE OF CAPSID PROTEIN INTERACTIONS IN THE DETERMINATION OF PARVOVIRAL TROPISM AND PATHOGENICITY. Mavis Agbandje-McKenna[1], Antonio Llamas-Saiz[2], Concepción Foces-Foces[2], Eva Hernando[3], Jose M. Almendral[3], Maria Kontou[1], Ian Portman[1], Robert McKenna[1]. [1]Department of Biological Sciences, University of Warwick, Coventry, CV4 7AL, UK; [2]Departmento de Cristografía, Instituto de Química-Física "Rocasolano", CSIC, Serrano 119, 28006 Madrid, Spain; [3]Centro de Biología Molecular "Severo Ochoa" (UAM-CSIC), Universidad Autónoma de Madrid, Cantoblanco, 28049 Madrid, Spain.

The successful infection of a host cell by a virion involves a series of macromolecular interactions. For the ssDNA parvoviruses, including minute virus of mice (MVM), canine parvovirus (CPV), feline parvovirus, porcine parvovirus and Aleutian mink disease parvovirus , the capsid protein has been shown to play a crucial role in host cell tissue tropism *in vitro* and pathogenicity *in vivo*. Two allotropic variants of MVM, MVMp (prototype fibrotropic strain) and MVMi (immunosuppressive strain), can serve as ideal models for defining tropism and pathogenicity-specific capsid interactions for the *Parvoviridae*, as a result of their pronounced differences in tissue tropism and pathogenicity, despite their 97% identity at the nucleotide level, with only 14 amino acids differing between the sequence of their major capsid protein, VP2.

The high resolution structure of infectious virions and empty capsids of MVMi has been determined by X-ray crystallography. Analysis of the MVMi capsid structure indicated that amino acids which differ between MVMi and MVMp, and have been identified, by molecular genetics, as being important for host tropism are clustered on the capsid surface, most likely forming a surface feature used for receptor recognition. The residues are involved in both intra- and inter-subunit interactions. This analysis also suggested that capsid stabilising interactions in MVMi involving allotropic amino acids were less likely to exist in MVMp, offering a possible explanation for their observed tropism differences since the block in restricted infections appears to be due to the inability of this capsid region to interact with differentiation specific host cell factors. The structure of the MVMp capsid has been determined to 3.25Å resolution. The analysis of the MVMp capsid structure, its comparison to the available MVMi capsid structure and the functional implications of their capsid protein interactions, particularly with respect to *in vitro* tissue tropism and *in vivo* pathogenicity, will be presented.

P12.04.006 CRYSTAL STRUCTURE OF TOBACCO NECROSIS VIRUS AT 2.25 Å RESOLUTION. K. Fukuyama, Y. Oda, K. Saeki, Department of Biology, Osaka University, Toyonaka, Osaka 560-0043, Japan, T. Maeda, Research Institute for Bioresouces, Okayama University, Kurashiki, Okayama 710-0046, Japan and H. Naitow, T. Tsukihara, Institute for Protein Research, Osaka University, Suita, Osaka 565-0871, Japan

Tobacco necrosis virus (TNV) is a spherical virus and is often associated with its satellite virus, satellite tobacco necrosis virus. TNV contains ss-RNA as a genome which is about 3.8 kb long. The virus shell consists of 180 subunits of a single protein (ca. 30 kDa), which are arranged in a T=3 icosahedral surface lattice. The amino acid sequence of the coat protein of TNV used in this study was determined by protein and c-DNA analyses. TNV was crystallized in the space group $P4_232$ with a=b=c=336.4 Å and two particles are in the unit cell [1,2]. The asymmetric unit contains 15 subunits (5 subunits for each A, B, and C subunits).

X-ray diffraction data were collected at room temperature with oscillation method ($\Delta\omega$=0.5°) using synchrotron radiation (λ=1.00 Å) of BL6A at PF, Tsukuba, Japan. 298,768 unique data to 2.25 Å resolution were obtained with R_{merge}=7.9 % and completeness=99 %. Starting from the ($2F_o$-F_c) map at 5 Å resolution [3], the resolution of the map was extended by solvent flattening and 5-fold averaging of the electron density. Most amino acid residues could be unambiguously identified in the final electron density map. 86 residues at the amino-termini of the A and B subunits and 56 residues of the C subunit were disordered. Refinement by X-PLOR yielded R=25.3 % and R_{free}=27.3 % for the 2.25 Å resolution data. The subunit proteins have Jelly roll barrel structure. Five Ca ions per icosahedral asymmetric unit are located at the interface of the subunits. Detailed structure of TNV and structural comparison with other viruses will be presented.

P12.04.007 STRUCTURE CHARACTERISTICS OF HIV-1 MUTANT INHIBITORS OF HYDROXYETHYLAMINE TYPE. J.Hasek, J.Duskova, J.Dohnalek, H.Jerabkova, E.Buchtelova. Institute of Macromolec.Chemistry, Academy of Sciences of the Czech Republic, Heyrovskeho nam.2, 162 06 Praha 6.

The structures studied in our group include HIV-1 protease BRU-1 and its mutants V82A, G48V/L91M and A71V/V82T/I85V complexed with subnanomolar (K_i range 0.02-200 nMol) inhibitors Boc- Phe- Ψ[(R/S)CHX CH_2 NH] - Phe - Glu/Gln/Ile - Phe - NH_2 /1/. The measurement under liquid nitrogen temperatures allowed us to localize up to several hundreds of solvent water molecules. In some cases, the glycerol molecules used as cryo-protectant for flash-freezing of the crystal were found adsorbed at the surface of protease. The bonding between HIV PR and inhibitor was defined uniquely in all cases /2,3,4/.

The efficiency of hydroethylamine inhibitors of HIV PR was attributed, at least in former works from early ninetieths, mainly to placement of the hydroxyl group between asp(25) and asp(125), i.e. to the site, where activated water forming the transition state of substrate is theoreticaly supposed. However, the hydroxyl groups in several complexes of N-protected tetrapeptide hydroxyethylamine inhibitors are bonded differently and do not fit the former supposition. It confirms that the main role of hydroxyl group is to protect splitting and that its bonding between aspartates 25, 125 is not of principal importance for inhibitor bonding. The supposed OH hydrogen bonding in the "active site" is replaced by hydrogen bonds formed by other groups of the inhibitor in some cases.

The principal project is supported by GACR 203/98/PO31, GAAV A4050811 and the experimental equipment was supported by 203/98/K023.

P12.04.009 HOW ADENOVIRUS BINDS SINGLE-STRANDED DNA. Jörg Hendle, Panagiotis N. Kanellopoulos, Bas van Breukelen[#], Peter C. van der Vliet[#] & Paul A. Tucker. European Molecular Biology Laboratory – Hamburg Outstation, Notkestr. 85, 22603 Hamburg, Germany and [#]Department of Physiological Chemistry, Utrecht University, 3508 TA Utrecht, The Netherlands

The adenovirus DNA binding protein from adenovirus type 5 binds to single-stranded DNA cooperatively, and non-sequence specifically. The protein is involved in DNA replication, regulation of mRNA formation and selection of host-range specificity. The two zinc ions required for activity do not bind DNA directly but stabilize structural motifs involved in the binding of DNA.

The 17 residues of the C-terminus are in an extended conformation and form a hook-like structure that tightly interacts with the next molecule thereby forming a chain of proteins crucial for the cooperative binding of single-stranded DNA. Asn512 is the hinge residue connecting the globular core of the protein with the C-terminal hook (1, 2). Thus Asn512 may provide the flexibility essential for the different types of protein-protein and protein-DNA interaction allowing the DNA binding protein a wide range of substrates in terms of DNA conformation and sequence.

The crystal structure of the Asn512Pro mutant determined at 2.3 Å resolution shows a better defined and more rigid molecule relative to the wild type structure. The distribution of temperature factors and the quality of the electron density map of the model allow us to suggest a number of corrections to the wild type structure. The biochemical data on hinge region mutants including results from DNA unwinding assays and *in vitro* replication assays will be presented.

P12.04.010 THE STRUCTURE OF HUMAN HEXOKINASE I MONOMER MADE POSSIBLE DUE TO MUTATIONS IN DIMER INTERFACE: A NEW INSIGHT ON REGULATION OF ATP AFFINITY. A.E. Aleshin, X. Liu, H.J. Fromm, R.B. Honzatko Department of Biochemistry and Biophysics, Iowa State University, Ames, IA 50011, USA; G.P. Bourenkov, H.D. Bartunik, MPG-ASMB, c/o DESY, Notkestrasse 85, 22603 Hamburg, Germany .

Hexokinase is the first enzyme of the glycolytic pathway. Hexokinase I and two other mammalian isozymes share a specific structure, which arises putatively from the duplication and fusion of a primordial gene for 50 kDa hexokinase. Hexokinase I, expressed in brain and red blood cells, is inhibited by its product glucose-6-phosphate (G6P) and relieved of that inhibition by inorganic phosphate (Pi). At low concentrations hexokinase I is a monomer, but it dimerizes at concentrations above 1 mg/ml.

Recent crystallographic structures of recombinant human hexokinase I are of a dimer, the relationship of which to the kinetically characterized monomer is unclear. Here we present the structures of a hexokinase I monomer made possible by mutations which disrupt the dimer interface. The monomer, complexed with G6P and glucose, has a rod-like conformation almost identical to

that of a subunite of the dimer. Another structure of monomeric hexokinase I was obtained by soaking the crystals with ADP. It provides for the first time a reliable information about the location of the ATP binding site in hexokinases. The comparison of conformations of G6P and ADP bound structures suggests how the N-terminal half of the enzyme could regulate ATP affinity.

An additional ADP molecule binds to hexokinase I near its N-terminal helix, which is known to anchor the enzyme to the mitochondrial membrane. This additional binding site may be involved in transport of ADP to mitochondrial matrix.

P12.04.011 Cd^{2+}-SUBSTITUTED CARBOXYPEPTIDASE A: NEW INSIGHT INTO THE CATALYTIC MECHANISM. Anette Frost Jensen, Jens Thostrup Bukrinsky, and Sine Larsen, Centre for Crystallographic Studies, Department of Chemistry, University of Copenhagen, Universitetsparken 5, DK-2100 Copenhagen, Denmark, and Morten J. Bjerrum, Chemistry Department, The Royal Veterinary and Agricultural University, Thorvaldsensvej 40, DK-1871 Frederiksberg C, Denmark.

Carboxypeptidase A from bovine pancreas is a zinc enzyme. The enzyme catalyses the hydrolysis of peptide bonds from the C-terminal, with a preference for substrates which have an aromatic residue at the n-1 position.When Zn^{2+} is replaced by Cd^{2+}, the enzyme retains 30% of the native activity with optimum around pH 7.5. Chloride ions are known to affect the reaction. Since Zn^{2+} is spectroscopically silent, the chemically similar Cd^{2+} has been substituted in the enzyme as a probe in NMR and PAC (perturbed angular correlation of γ-rays spectroscopy) investigations of the Cd^{2+}-ligand interactions.

We have collected data from Cd^{2+}-substituted crystals produced at three different conditions, CdCPA(7.5): pH 7.5, low (2 mM) chloride concentration, CdCPA(7.5, Cl): pH 7.5, high (250 mM) chloride concentration, CdCPA(5.5): pH 5.5, low chloride concentration. The resolution varies from 1.72 Å to 2.00 Å with 90-95 % complete data in the outer resolution shell. All three structures show identical coordination environment of the Cd^{2+} which is six-coordinated. Three protein ligands, two histidines and one glutamic acid coordinate as well as two water molecules. The native Zn^{2+} has the same protein ligands but has only one water coordinating. No specific binding sites for the chloride ions have been found.

The coordination geometry of the Cd^{2+} enzyme is a good model for the enzyme-substrate binding in the native enzyme and it reveals new aspects of the reaction mechanism. Previously, the Cd^{2+} enzyme was considered to be five-coordinated as the native enzyme. This assumption was based on an unrefined structure. New interpretation of the spectroscopic results are thus required. This work shows that accurate determination of protein structures are important to fully understand mechanistic features studied by other techniques.

This work was supported by the Danish National Research Foundation.

P12.04.012 CRYSTAL STRUCTURE OF THE E. COLI NITROREDUCTASE PROTEIN. GN Parkinson, JV Skelly, DA Suter and S Neidle The CRC Biomolecular Structure Unit, Institute of Cancer Research, Sutton, Surrey SM2 5NG, UK

E. Coli nitroreductase catalyses the reduction of nitro groups to the corresponding hydroxylamines, which can then be further activated to form cytotoxic DNA cross-linking agents. The enzyme has been used in several prodrug approaches (ADEPT, GDEPT and VDEPT) for the tumour-selective activation of cytotoxic alkylating drugs, notably the aziridinyl prodrug CB1954.

We have determined the three-dimensional structure of this enzyme, in order to gain insight into the mechanism of activation, and to provide a basis for the rational design of more effective prodrugs.

The recombinant 24kD enzyme was crystallised in the tetragonal space group $P4_32_12$, with unit cell dimensions of a=b=57.74 Å and c=275.51 Å and two molecules in the asymmetric unit. Diffraction data to 2.14 Å was collected on a laboratory R-AXISII image-plate. The crystal structure has been solved by molecular replacement methods, using X-PLOR, and employing the recently-determined structure of the nitroreductase Frase I (PDB code IVFR), as a starting model. There is 31.3% sequence homology between the two enzymes. The structure is currently being refined using X-PLOR. Details of the structure, in particular the active site geometry, will be presented.

P12.04.013 CRYSTALLOGRAPHIC INSIGHTS INTO THE HYDRIDE TRANSFER MECHANISM OF NADPH-CYTOCHROME P450 REDUCTASE. Paul A. Hubbard, Rosemary Paschke, *Anna Shen, *Charles B. Kasper, and Jung-Ja P. Kim. Dept. Of Biochemistry, Medical College of Wisconsin, Milwaukee, WI 53226 and *McArdle Labortaory for Cancer Reseach, University of Wisconsin - Madison, WI 53706, USA.

NADPH-cytochrome P450 oxidoreductase (CPR) is a monomeric enzyme bound to the outer face of the endoplasmic reticulum of all mammalian cells. Its primary function is that of electron transfer from the two electron donor of NADPH to the one electron heme acceptor, cytochrome P450 via the FAD and FMN redox centers. The structure from expressed rat protein was previously solved in our lab, and shown to contain two structurally homologous regions; a flavodoxin like FMN domain and a ferredoxin-$NADP^+$ reductase like fold which binds cofactors NADPH and FAD in two separate domains. Between the two flavin cofactors is a linking domain with no sequence homology to any other known protein. The indole ring of W677, the penultimate residue, is seen to stack against the *re*-face of the FAD, presumably stabilizing an inactive conformation by preventing direct hydride transfer between NADPH and the flavin.

The cloned rat gene was mutated to remove the two C-terminal residues W677 and S678, and the purified protein was shown to retain stoichiometric amounts of FMN and FAD. Crystals were grown at 19.5^{o}C under similar conditions to that of the wild type in the presence of $NADP^+$. Diffraction data were collected and processed with Denzo to 2.7A resolution using an R-AXIS II image plate at 4 ^{o}C. The structure was solved with CNS by using the difference Fourier method, using phases calculated from the refined native structure. Results are in agreement with previous proposals, and clearly show the A-face of the nicotinamide moiety stacking against the *re*-face of the isoalloxazine ring of FAD. The pyrophosphate linkage of the cofactor has undergone significant rotation in order to achieve an almost perpendicular orientation to that found in the crystal structure of the wild type. This adds further evidence to the direct hydride transfer mechanism previously proposed.

P12.04.014 UNDERSTANDING THE ACTIVE SITE OF AN ENZYME : CRYSTAL STRUCTURES OF ESCHERICHIA COLI NAD-SYNTHETASE Rosario Recacha[1], Caroline Ozment [1], Joseph Barchue [1], Dharmalingam Prahadeeswaran [1], Lawrence J. DeLucas [1] & D. Chattopadhyay [1,2], [1] Center for Macromolecular Crystallography, University of Alabama at Birmingham, Birmingham, AL 35294, USA, [2] Division of Geographic Medicine, School of Medicine

NAD and NADP are essential coenzymes for all living organisms. NAD can be synthesized either de novo or through salvage pathway. These two pathways converge at the level of nicotinic acid mononucleotide and the two final steps on the biosynthetic pathway are in common. The enzyme NAD-

synthetase [EC 6.3.5.1], which belongs to the amidotransferase family, catalyzes the final step in the Priess-Handler pathway for NAD synthesis. This reaction involves transfer of an amino group from ammonia (or glutamine) to nicotinic acid adenine dinucleotide (NAAD) in the presence of ATP and magnesium. Bacterial enzymes use ammonia in preference to glutamine. The reaction consists of two steps. In the first step, ATP hydrolysis occurs and adenylated-NAD is formed. In the second step, NAD is formed via nucleophilic addition of ammonia. We have determined the crystal structure of E. coli NAD-synthetase in the free enzyme form, in complex with NAAD and ATP, and in complex with NAAD and a non-hydrolyzable ATP-analogue. All structures are refined to at least 2.0 Å resolution. The overall structure of the enzyme is very similar to the only known structure of NAD-synthetase enzyme (from Bacillus subtilis). These structures reveal the substrates and divalent cation binding sites. The NAAD and ATP complex structure determined at 1.8 A resolution shows the active site accommodating an adenylated reaction intermediate.

P12.04.015 STRUCTURAL BASIS FOR THE SUBSTRATE SPECIFICITY OF PROTEIN TYROSINE PHOSPHATASES J. Yang, Z. Cheng, T. Niu, X. Liang, G.W. Zhou [1], Z.J. Zhao [2], [1] Program in Molecular Medicine, University of Massachusetts Medical School, Worcester, Massachusetts 01605, USA, [2] Department of Medicine, Vanderbilt University, Nashville, Tennessee 37232, USA

Protein tyrosine phosphatases (PTPs) are a group of structurally and functionally diversified enzymes. Precise regulation of their physiological functions depends largely on their substrate specificity. SHP-1, a SH2 domain containing PTP, is an important negative regulator in the B cell antigen receptor, T cell antigen receptor, c-Kit and cytokine signal transduction pathways. Deficiency of SHP-1 will result in severe abnormalities in the immune system. We have determined the crystal structures of the catalytic domain of SHP-1 complexed with two phosphotyrosyl decapeptides, pY469 and pY495, originated from its physiological substrate SIRP. The structures have been refined to crystallographic R values of 19.9% and 20.5%, respectively. Both peptides bound to the catalytic domain of SHP-1 in extended conformations. From the complex structures, we identified six well-defined substrate binding sub-pockets. This is the first time that the substrate binding sub-pockets of a PTP are identified. The substrate specificity of SHP-1 is determined by the residues at P-4 and even further minus positions in the phosphotyrosyl substrates, and the recognition sites for these residues are the beta5-loop-beta6 motif and loop beta6/beta7 in the enzyme. We also observed a novel residue shift at the hydrophobic P-2 sub-pocket. The P-2 sub-pocket bound the P-2 Leu residue in the pY469 complex structure and the P-3 Phe residue in the pY495 complex structure. Since the hydrophobic P-2 sub-pocket is highly conserved in PTPs, the residue shift may be a common phenomenon for PTPs. This novel residue shift has provided a new guideline for identifying substrates for PTPs. We also compared other native PTPs structures with our complex structures. We concluded that the substrate specificity of PTPs may be determined by two regions: the P-4 and further minus sites, and the P+4 and even further plus sites, in the phosphotyrosyl substrates. The recognition of these two regions comes from the hyper-variable beta5-loop-beta6 and the alpha5-loop-alpha6 motifs in PTPs.

P12.04.016 MOLECULAR STRUCTURE OF IMP DEHYDROGENASE FROM *STREPTOCOCCUS PYOGENES*. Rong-guang Zhang, Gwyndaf Evans, Eliezer Huberman, Andrzej Joachimiak, Frank Rotella, Edwin M. Westbrook, and Frank R. Collart, Argonne National Laboratory, Argonne, IL 60439 USA.

IMP dehydrogenase (IMPDH) is an essential enzyme that catalyzes the first step unique to GTP synthesis. To provide a basis for the evaluation of IMPDH inhibitors as antimicrobial agents, we have expressed and characterized IMPDH from the pathogenic bacterium, Streptococcus pyogenes. Our results show that the biochemical and kinetic characteristics of S. pyogenes IMPDH are similar to other bacterial IMPDH enzymes. However, the lack of sensitivity to mycophenolic acid and the Km for NAD (1180 μM) exemplify some of the differences between the bacterial and mammalian IMPDH enzymes, making it an attractive target for antimicrobial agents. To evaluate the basis for these differences, we determined the crystal structure of the bacterial enzyme at 1.9 Å with substrate bound in the catalytic site. The structure was determined using selenomethionine-substituted protein and multi-wavelength anomalous (MAD) analysis of data obtained with synchrotron radiation from the undulator beamline (19ID) of the Structural Biology Center at Argonne's Advanced Photon Source. S. pyogenes IMPDH is a tetramer with its four subunits related by a crystallographic fourfold axis. The protein is composed of two domains: a TIM barrel domain that embodies the catalytic framework and a cystathione (-synthase (CBS) dimer domain of so far unknown function. Using information provided by sequence alignments and the crystal structure, we prepared several site-specific mutants to examine the role of various active site regions in catalysis. These variants implicate the active site flap as an essential catalytic element and indicate there are significant differences in the catalytic environment of bacterial and mammalian IMPDH enzymes. Comparison of the structure of bacterial IMPDH with the known partial structures from eukaryotic organisms will provide an explanation of their distinct properties and contribute to the design of specific bacterial IMPDH inhibitors. This work was supported by the US Department of Energy, Office of Biological and Environmental Research, under Contract W-31-109-ENG-38.

P12.04.017 CHARACTERIZATION OF HUMAN BONE ALKALINE PHOSPHATASE IN *PICHIA PASTORIS*. Christine C. Malone, Eva Ciszak and Laurel J. Karr, USRA, Huntsville, Alabama 35810 and SD48, NASA/MSFC, Huntsville, Alabama 35812.

A soluble form of human bone alkaline phosphatase has been expressed in a recombinant strain of the methylotrophic yeast *Pichia pastoris*. We constructed a plasmid containing cDNA encoding for human bone alkaline phosphatase, with the hydrophobic carboxyl terminal portion deleted. Alkaline phosphatase was secreted into the medium to a level of 32mg/L when cultured in shake flasks, and enzyme activity was 12U/mg, as measured by a spectrophotometric assay. By conversion to a fermentation system, a yield of 880mg/L has been achieved with an enzyme activity of 968U/mg. By gel electrophoresis analysis, it appears that greater than 50% of the total protein in the fermentation media is alkaline phosphatase.

Although purification procedures are not yet completely optimized, they are expected to include filtration, ion exchange and affinity chromatography. Our presentation will focus on the purification and crystallization results up to the time of the conference. Structural data should provide additional information on the role of alkaline phosphatase in normal bone mineralization and in certain bone mineralization anomalies.

P12.04.114 STRUCTURE-ACTIVITY CORRELATIONS AMONG A SERIES OF HYBRID TMQ-PTX ANALOGUES COMPLEXED WITH HUMAN DHFR. Vivian Cody, Nikolai Galitsky, Joe Luft, Walt Pangborn Aleem Gangjee Molecular Biophysics Department, Hauptman-Woodward Medical Res. Inst, Buffalo, NY,14203 USA. Division of Medicinal Chemistry, Duquesne University, Pittsburgh, PA 15282

Pneumonia caused by opportunistic infectious agents is a major cause of mortality among patients with AIDS. Antifolates have been shown effective adainst the dihydrofolate reductase (DHFR) from Pneumocystis carinii (pc) which is a target for drug design studies. The lipophilic quinazoline trimetrexate (TMQ) and the pyridopyrimidine piritrexim (PTX) are potent inhibitors of human DHFR with moderate potency for pcDHFR. To further optimize pcDHFR selectivity, a series of hybrid analogues combining the pyridopyrimidine of PTX with the trimethoxy anilino group of TMQ were made, including those with reversed C9-N10 bridge modifications. Inhibition data against rat liver (rl) and pcDHFR were enhanced by N-methylation. To understand these structure-activity relationships we report crystal data for nine hDHFR complexes with TMQ and two of its hybrid analogues, including the first structural data for a reversed bridge antifolate. One complex crystallizes in a tetragonal space group and the others are rhombehedral; however, two crystallize in an independent R3 lattice. Of these, only one is a ternary complex with NADPH, even though all were co-crystallized in the presence of cofactor. Differences in the packing of hDHFR in the alternate R3 lattice result in better definition of flexible outer loop regions compared to the predominate R3 lattice. All inhibitor conformations are similar to each other and to methotrexate (MTX), including the reversed bridge analogues. When these inhibitors were modeled in the active site of pcDHFR, all hydrophobic contacts were weaker than in hDHFR, consistent with their decreased potency against pcDHFR. Although the bridge conformations were similar, the orientation of the N10-methyl in the most potent and selective of this series differs and makes tighter contacts to Leu-22 than MTX. PcDHFR selectivity (rl/pc ratio) is increased 10-fold for all N-methyl analogues, while reversed bridge analogues lower potency, but not selectivity. The presence of a 5-methyl substituent also enhances potency and selectivity. Compared to TMQ, the N8 of these hybrides interact with the conserved water that forms a hydrogen bond network with Glu-30 and Trp-24 in hDHFR. Supported in part by GM-51670 (VC) and AI-30900 (AG).

P12.04.115 RATIONAL DESIGN OF FLAVONOIDS AS POTENTIAL ALDOSE AND ALDEHYDE REDUCTASE INHIBITORS. Elisabeth V. Fletcher, Roland P.-T. Chung, Mark von Itzstein and Ossama El-Kabbani, Department of Medicinal Chemistry, Victorian College of Pharmacy, Monash University, Parkville, VIC 3052 Australia

It has been shown that aldose reductase (ALR2) is implicated in the development of diabetic complications. Thus ALR2 inhibitors seem to offer the possibility of preventing or arresting the progression of the complications. The search for effective ALR2 inhibitors has been underway for 25 years but as yet have not proven to be unequivocally effective.

Naturally occurring flavonic compounds (2-phenyl-4H-1-benzopyran-4-one derivatives) are known to exert several pharmacological activities. In particular they are antioxidants and are able to inhibit ALR2 and the related aldehyde reductase (ALR1).

Several flavonoids, known to exhibit ALR2 inhibition, have been modelled in the active sites of the recent structures of ALR1 and ALR2.[1] Based on the corresponding binding energies we have designed several novel molecules, incorporating a carboxylate (a functional group present in ALR1 and ALR2 inhibitors[1]) into the flavonoid molecule. The carboxylate is hydrogen bonded to the active site residues Tyr 48, His 110 and Trp111, whilst π-stacking is also observed between Trp 219 and the hydrophobic ring of the flavonoid molecule.

A crystal structure determination of ALR1 in complex with coenzyme and flavonoid is currently underway. Data obtained from the structure will be used in further refinement of inhibitors.

P12.04.116 STRUCTURAL ANALYSIS OF PNEUMOCYSTIS CARINII DHFR TERNARY COMPLEX WITH A NOVEL PYRROLO ANTIFOLATE. Nikolai Galitsky, Vivian Cody, Dawn Rak, Walt Pangborn, Aleem Gangjee. Department of Molecular Biophysics, Hauptman-Woodward Medical Research Institute, Buffalo, NY. School of Pharmacy, Duquesne University, Pittsburgh, PA

Pyrrolo[2,3-d]pyrimidine based antifolates are a new class of inhibitors that have a 6-5 ring system instead of the conventional bicyclic 6-6 fused ring system of pteridine, quinazoline or pyrido[2,3-d]pyrimidine. These antifolates have been shown effective anticancer agents against a number tumor cell lines and as shown by the pyrrolopyrimidine, LY231514, which has a 4-oxo substituent, is a multitarget antifolate. Although the parent of LY231514 was designed as an inhibitor of thymidylate synthase, it inhibits at least five enzymes in the folate pathway, including dihydrofolate reductase (DHFR). Data from a series of pyrrolopyrimidine derivatives of the antibacterial trimethoprim in which the 4-amino group was cyclised, showed that a 6-methyl derivative had equivalent activity to trimethoprim. Structural data for the E. coli DHFR complex showed that these rigid analogues bind with the same orientation as trimethoprim. To further define the structure activity correlations among pyrrolopyrimidine antifolates, a 4-methyl derivative of the novel pyrrolo[2,3-d]pyrimidine classical antifolate was synthesized and shown as active as methotrexate against hDHFR. We report the first crystal structure of Pneumocystis carinii DHFR ternary complex with NADP+ and N-[4-[2-(2-amino-3,4-dihydro-4-methyl-7H-pyrrolo[2,3-d]pyrimidin-5-yl)ethyl]benzoyl]-L-glutamic acid, collected to 2.1A resolution on an RaxisIV at room temperature. Analysis of these data, currently refined to 2.4A resolution, show that the pyrrolopyrimidine ring is oriented such that the pyrrolo N hydrogen bonds to a conserved water that is between Glu-32 and Trp-27, similiar to that of the novel furopyrimidine classical antifolate reported previously. This orientation places the 4-methyl group in a hydrophilic pocket normally occupied by the 4-amino group of antifolates, and differs from that of the trimethoprim pyrrolopyrimidine derivative. These data suggest that the antifolate shifts its position in the active site such that the 4-methyl contacts are greater than those for the 4-amino of the furopyrimidine structure, thereby relieving the strain of these contacts. When this structure is compared to the hDHFR furopyrimidine complex, it is noted that the 4-amino contacts are weaker in hDHFR than in pcDHFR. Supported in part by GM-51670 (VC) and AI-41473 (AG).

P12.04.117 PLASMEPSIN II, A HEMOGLOBIN-DEGRADING ENZYME FROM *P. FALCIPARUM,* IN COMPLEX WITH NON-PEPTIDIC INHIBITORS. Abelardo. M. Silva, R. Randad, D. Medjahed, S. V. Gulnik, B.Yu, J. W. Erickson, T.S. Haque[1], J. Ellman[1], Structural Biochemistry Program, National Cancer Institute/SAIC, Frederick, Maryland 21702, USA. (1) Department of Chemistry, University of California, Berkeley, CA 94720, USA.

Malaria, a disease caused by parasites of the genus *Plasmodium*, is among the most widespread infectious diseases in the world, afflicting several hundred million and killing nearly two million people per year, mainly children. *P. falciparum*, invades erythrocytes and consumes nearly all of its host's hemoglobin as a source of nutrients during growth and development. The parasite encodes two homologous aspartic proteases - plasmepsins I and II - which are essential components of its hemoglobin degradation pathway and are novel targets for

antimalarial drug development. We described earlier the crystal structure of plasmepsin II in complex with pepstatin A, which was the first report of a protein structure from *P. falciparum*. We present now the structures of plasmepsin II in complex with potent non-peptidic inhibitors of the enzyme, which also inhibit the growth of *P. falciparum* in culture. Inhibitors were designed on the basis of our first structure, and also derived from combinatorial libraries. Two new crystal forms were found. One of them corresponds to the space group P2, with one molecule in the asymmetric unit. Monomers interdigitate around a crystallographic two-fold axis burying an area exceeding 2000 $Å^2$. The second form corresponds to space group I222 with one molecule in the asymmetric unit. The monomers also extensively interact around a crystallographic two-fold axis, and while the surfaces in contact are the same observed in monoclinic and trigonal crystals, the relative orientation of the monomers is different. Interactions mediated by a second two-fold axis, although less extensive than the first one, are also observed. All these structures show the high variability in dimeric interactions; an unusual flexibility of the binding cavity; and, open the question about the state of aggregation of the functional enzyme, which directly affects the structure of the binding cavity itself.

P12.04.118 CRYSTAL STRUCTURE OF THE BIFUNCTIONAL N-ACETYLGLUCOSAMINE 1-PHOSPHATE URIDYLTRANSFERASE (GLMU). Kieron Brown [1], Suzanne Dixon [1], Frederique Pompeo [2], Dominique Mengin-Lecreulx [2], Christian Cambillau [1], Yves Bourne [1]. [1] AFMB-CNRS, 31 ch. J. Aiguier, 13402 Marseille, France. [2] CNRS, Universite Paris-Sud, 91405 Orsay cedex, France.

N-acetylglucosamine 1-phosphate uridyltransferase (GlmU) is a unique cytoplasmic bifunctional enzyme involved in the biosynthesis of the nucleotide activated UDP-GlcNAc which is the most important precursor for the biosynthetic pathways of peptidoglycan and lipopolysaccharide in bacteria. The crystal structure of a truncated form of GlmU has been solved at 2.25A resolution using multiwavelength anomalous dispersion techniques.

The structure is composed of two separate domains connected by a long alpha-helical arm, an N-terminal domain is consistent with the dinucleotide-binding Rossmann fold, and a C-terminal domain which adopts a left-handed parallel beta-helix structure found in homologous bacterial acetyltransferases. The structure reveals the binding site of the product UDP-GlcNAc, and exemplifies a prototypic structure for other members of the large family of XDP-sugar bacterial pyrophosphorylase enzymes which share sequence homology with the N-terminal domain of GlmU.

P12.04.119 1.9Å STRUCTURE OF HSV THYMIDINE KINASE: LIGAND BINDING TO NATIVE AND MUTANT ENZYMES. M.R. Sanderson, M.S. Bennett, F.Wien and J.N. Champness, Division of Biomedical Sciences, Randall Institute, King's College, 26-29 Drury Lane, London, WC2B 5RL, UK, and W.C. Summers, Department of Therapeutic Radiology, Yale University School of Medicine, 333 Cedar Street, New Haven, CT 06520-8040, USA, and Hongmao Sun and George Wright, Department of Pharmacology, University of Massachusetts Medical School, Worcester, MA 01655, USA, and M.E. Black, Division of Biology and Biomedical Sciences, Washington University, 660 S. Euclid Avenue, St. Louis, MO 63110-1093, USA.

Viral thymidine kinase provides the first step in the activation of anti-herpes drugs such as aciclovir (Zovirax). Highest resolution structures to date (1.9Å) of ligand/enzyme complexes have revealed significant details of interactions of drug molecules with the enzyme active site, and these studies, as well as studies of ligand binding to mutant enzyme, will be presented. The results are of value in the development of more effective chemotherapy, not only for herpes infections, but also, potentially, in gene-therapy of brain tumours which have been made to express the enzyme by transfection.

P12.04.120 STRUCTURE OF DIHYDROFOLATE REDUCTASE OF M. TUBERCULOSIS: NEW TB-SPECIFIC DRUG POSSIBILITIES REVEALED. Rongbao Li[a,b], Worachart Sirawaraporn[c] and Wim G. J. Hol[a,b,d], [a]Department of Biological Structure, [b]Howard Hughes Medical Institute and Biomolecular Structure Center, University of Washington, Seattle, WA 98195, USA; [c]Department of Biochemistry, Mahidol University, Bangkok 10400 Thailand; [d]Department of Biochemistry, University of Washington, Seattle, WA 98195, USA

Dihydrofolate reductase catalyzes the NADPH-dependent reduction of dihydrofolate to tetrahydrofolate and is essential for the synthesis of thymidylate, and therefore of DNA. Inhibition of the enzyme activity leads to the halt of DNA synthesis and cell death, thus the enzyme has been studied extensively as a drug target for several diseases, including bacterial, protozoal and fungal infections, neoplastic diseases and autoimmune diseases. Dihydrofolate reductase from Mycobacterium tuberculosis, a human pathogen responsible for the death of millions every year, has been co-crystallized with its co-factor NADPH and methotrexate and trimethoprim, two inhibitors being employed as antitumor and antimicrobial therapeutic agents. The crystals have one molecule in the asymmetric unit and are in space group P41. The crystal structures of two ternary complexes containing NADPH and methotrexate or trimethoprim, and of one binary complex containing NADPH have been determined to 1.7 Å resolution by single isomorphous replacement plus anomalous scattering followed by phase improvement with solvent flattening procedures. Structural comparison of these complexes with human dihydrofolate reductase indicates that the protein fold is similar but the environments of both NADPH and the inhibitors contain interesting differences, which can be exploited for designing selective inhibitors to tubercular dihydrofolate reductase. Therefore, dihydrofolate reductase of M. tuberculosis provides a potential TB drug target.

P12.04.121 DISCOVERY OF THE MODES OF ACTION OF INHIBITORS OF EUKARIOTIC TOPOISOMERASE I. Paulene M. Quigley[a], Matthew R. Redinbo[b], James J. Champoux[c], Wim G. J. Hol[a,b,d], [a]Department of Chemistry, University of Washington, WA 98195 USA; [b]Biomolecular Structure Center, University of Washington, Seattle, WA 98195, USA; [c]Department of Microbiology, University of Washington, Seattle, WA 98195, USA; [d]Howard Hughes Medical Institute, University of Washington, Seattle WA, 98195 USA.

Topoisomerase I functions in eukariotic cells to relax the superhelicale tension generated by essential processes such as DNA replication. Cancer cells show particular sensitivity to disruption of thes processes due to their high rate of proliferation. In fact drugs like camptothecin serve as an effective anti cancer treatments through their targeting of the Topoisomerase I-DNA complex. Despite the great variety of Topoisomerase I inhibitors that exist, their specific modes of action remains unclear. Hence, through the crystallization of Topoisomerase I-DNA complex with known inhibitors, we hope to elucidate the structural basis of inhibition and thereby lead to more potent treatments.

Structures of human topoisomerase I have revealed how the enzyme clamps around the DNA duplex to form a transient covalent complex between Tyr 723 and the 3'-hydroxyl of the

scissile strand. Camptothecin, a recently approved cancer drug, promotes the lifetime of this 'cleavage complex', thereby forming obstacles on the DNA highway, leading to cell death. Numerous other classes of topoisomerase poisons have been described, although their precise mode of action remains unclear. We hope to gain insight into the modes of action of Topoisomerase I inhibitors by crystallographic investigation.

P12.04.122 COMPARISON OF THE UNINHIBITED HUMAN FACTOR XA STRUCTURE AND THE TAP INHIBITED BOVINE FACTOR XA STRUCTURE. Anzhi Wei, Richard S. Alexander, Chong-Hwan Chang, DuPont Pharmaceuticals Company, Experimental Station, Wilmington, DE 19880, USA

The function of factor Xa is to convert prothrombin into thrombin which in turn converts fibrinogen into fibrin. The location of factor Xa at the intersection of the intrinsic and extrinsic paths of the coagulation cascade makes it an attractive antithrombotic drug target .

The crystal of apo human factor Xa was crystallized by using polyethylene glycol as a precipitant. The crystal belongs to space group $P4_12_12$ with unit cell dimensions of a=b=94 Å and c=119 Å, and diffracts to 2.0 Å resolution, which is higher than previously reported (2.5Å).

The bovine factor Xa was crystallized in complexed form with recombinant tick anticoagulant peptide (rTAP) with PEG 8000. The crystals were obtained in two different crystal forms : Form I belongs to space group $P4_22_12$ with unit cell dimensions of a=b=133.1 Å and c=68.8 Å and diffracts to 3.0 Å. Form II belongs to $P4_12_12$ (or $P4_32_12$) with dimensions of a=b=126.5 Å and c=146.7 Å; it contains two complexes per asymmetric unit and diffracts to 2.5 Å.

The sequence of bovine factor Xa shares a high sequence identity with the human factor Xa: light chain exhibits 70% and the heavy chain shows 84% identity. The sequence identity is noticeably higher around the calcium-binding and the catalytic regions. This homology reflects the functional importance of these two regions of factor Xa. Between the complexed bovine factor Xa and apo human factor Xa, the overall rms. deviation around Ca atoms is 1.03 Å and 0.92Å at the catalytic regions. The high homology between two species also reflects the general agreement of the results on the reaction between rTAP and bovine or human factor Xa.

The structures of apo human factor Xa and complexed rTAP_bovine factor Xa provide a key to understanding its novel mode of binding, the existence of a multi-step pathway for the inhibition of fXa by rTAP, and a possible use for designing new selective inhibitors of fXa. The details of the structural comparison between human and bovine fXa, will be presented.

P12.04.123 A COMBINATORIAL APPROACH TO THE CRYSTAL STRUCTURE OF TOPOISOMERASE I COMPLEXED WITH ANTICANCER DRUGS. Lance J. Stewart[1], Hidong Kim[1], Alex Burgin Jr.[2], David Zembower[3], Philippe Pourquier[4] and Yves Pommier[4]. [1]Emerald BioStructures, Inc., 7869 NE Day Rd. W, Bainbridge Island, WA 98110, USA; [2]San Diego State University, 5500 Campanile Dr., San Diego, CA 92182, USA; [3]MediChem Research, Inc., 12305 So. New Avenue, Lemont, IL 60439, USA; [4]National Cancer Institute, Laboratory of Molecular Pharmacology, Bethesda, MD 20892, USA

Human topoisomerase I (topo I) is the sole intracellular target of camptothecin (CPT) and other "topo I poisons," some of which are among the most promising anticancer drugs ever identified. Emerald BioStructures, Inc. is actively engaged in a phase I Small Business Innovative Research study that seeks to elucidate the X-ray crystal structure(s) of human topo I in ternary complex with DNA and topo I poisons which include CPT, derivatives thereof, and several other non-CPT anticancer compounds which target topo I. We have developed several new "combinatorial" crystallization research tools that have allowed us to rapidly identify crystal forms of human topo I whose growth depend on the presence of all three components: topo I, DNA, and poison. This combinatorial approach is generally applicable to any structure-based drug design project. The progress towards the X-ray structure determination of our topo I crystals will be presented.

P12.04.124 STRUCTURAL STUDIES OF LIGANDS BOUND TO THE IMMUNOSUPPRESION TARGET LCK. X. Zhu, P. Rose, D. R. Stover, H. Zhao, L. Toledo & K. A. Morgenstern, Kinetix Pharmaceuticals, Inc., 200 Boston Ave. Medford, MA 02155, USA

The tyrosine kinase lck is predominantly expressed in T cells and appears to be the first kinase activated upon the TCR/MHC engagement. As an attractive immunosuppression target, lck has been crystallized in our laboratory. We have determined the structures of this enzyme to high resolution with several specific and non-specific ATP-competitive inhibitors. These novel lck and inhibitor complexes display subtle but distinct protein conformations around the bound ligands. Correlated with our structural activity data, we show that the non-specific lck inhibitors interact with the residues well conserved in the kinase family. The lck-specific inhibitors, on the other hand, adopt the ATP bound conformation of the protein, and interact with several residues specific to lck. A comparison of the lck structures to other protein kinases bound with their specific inhibitors is also discussed. Finally, our complex structure of lck and an ATP analog reveals that the gamma phosphate is not in the proper conformation for phospho-transfer. Instead, it represents an intermediate step of the conformational transition from the apo form to the ternary complex of lck/ATP/substrate.

P12.04.125 CRYSTAL STRUCTURE OF MISTELTOE LECTIN I FROM VISCUM ALBUM. R. Krauspenhaar, S. Eschenburg, M. Perbandt (1), V. v. Kornilov (2), S. Stoeva, W. Voelter (3), N. V. Konareva, I. V. Mikailov, A. Mikhailov (4), C. Betzel (1), (1) Inst. of Physiol. Chemistry, Uni. Hamburg, Hamburg, Germany, (2) Inst. Cell Biophys. Russian Academy of Sciences, Pushino, Russian Federation (3) Inst. Physiol. Chem. Uni. Tübingen, Tübingen Germany, (4) Inst. Crystall. Russian Academy of Sciences, Russian Federation,

The crystal structure of the ribosome inactivating protein (RIP) misteltoe lectin I (ML-I) from Viscum album has been solved by M.R..

The structure has been refined to a crystallographic R-factor 24 % SR data up to 2.7 Angstrom resolution. The heterodimeric 63 kDa protein consists of a toxic A subunit which exhibits RNA-glycosidase activityand a galactose specific lectin B subunit. The overall protein fold is similar to that of ricin from Ricinus communis. Unlike ricin ML-I is already medically applied as a component of a commercially available misteltoe extract with immunostimulating potency for the treatment of human cancer. The 3D structure revealed structural details of this pharmaceitically important protein and will give more insights into the structure-function-relationship for further protein engeneering towards drug design studies. the relative high sequence homology and the conserved secondary structure enabled a structural accurate comparison to ricin and revealed differences in the vicinity o the active site, in the high galatose binding side as well as in the interface regions between A and B chain, which might account for the altered cytotoxitiy of ML-I.

Structural studies will be presented and compared to other known ribosome inactivating proteins.

P12.04.126 CRYSTAL STRUCTURE OF TETRA-DIMERIC C-TYPE LECTIN PROTEIN FLAVOCETIN-A FROM HABU VENOM. K. Fukuda [1], H. Mizuno, Z. Fujimoto [2], H. Atoda, T. Morita [3], [1] University of Tsukuba, Tsukuba Science City, Ibaraki 305-8572, Japan. [2] National Institute of Agrobiological Resources, Tsukuba Science City, Ibaraki 305-8602, Japan. [3] Meiji Pharmaceutical University, Kiyose, Tokyo 204-8588, Japan.

Flavocetin-A (FL-A) is a member of C-type lectin superfamily. FL-A was isolated and purified from the venom of habu snake Trimeresurus flavoviridis. Unlike other family members, it is a high molecular mass protein (149 kDa) composed of alpha-subunits of 16.5 kDa, 135 residues, and beta-subunits of 13.7 kDa, 125 residues. This protein binds specifically to glycoprotein (GP) Ib alpha-subunit in the platelet membrane GPIb-IX-V complex and functions as a competitive blocker of von Willebrand factor-binding in platelet agglutination under conditions of high shear stress. We have determined the X-ray crystal structure of FL-A as a first step in understanding the molecular basis for the GPIb-binding specificity.

The structure of FL-A was solved by molecular replacement using the structure of coagulation factors IX/X-binding protein (IX/X-bp) [1], a heterodimer of C-type lectin-like domains, as a search model (55% identity with the sequence of heterodimer subunit in FL-A). The current model has a crystallographic R-factor of 21.9% (free-R=30.5%) at 2.5 Å resolution. Expected from the structure of IX/X-bp, each subunit of FL-A showed an intertwined heterodimer fold made of disulfide-linked alpha- and beta-subunits. These subunits are related by a crystallographic fourfold symmetry parallel to the c-axis and connected by an additional disulfide-bond between C-terminal region in the alpha-subunit and N-terminal region in the beta-subunit. Thus, the overall structure of FL-A revealed a cyclic tetradimer $(alpha/beta)_4$ connected by alternate disulfide-linkages. It also displayed a large solvent channel inside the tetradimer molecule, and this is consistent with a relatively large solvent content of 67% in the crystal. Details of the structure of FL-A and comparison with IX/X-bp will be discussed.

1. H. Mizuno, Z. Fujimoto, M. Koizumi, H. Kano, H. Atoda, & T. Morita. (1997). Nature Struct. Biol., 4, 438-441.

P12.04.127 MOLECULAR REPLACEMENT STUDIES OF TRICHOSANTHES KIRILOWII LECTIN. M.Li, Y.-P.Wang, J.-J.Chai, R.-C.Bi [1], K.-Y.Wang [2], [1] Institute of Biophysics, Chinese Academy of Sciences, Beijing 100101, China, [2] Institute of Biochemistry,Chinese Academy of Sciences, Shanghai 200031, China

Trichosanthes Kirilowii lectin (TKL) was isolated and purified from the same plant tissue as trichosanthin [1], a type ¢ñ ribosome-inactivating protein(RIP) consisting of a single peptide chain. Like ricin [2], a type ¢ò RIP, it contains two peptide chains A and B each having a molecular weight of about 30kDa. TKL has some properties similar to those of trichosanthin or ricin, but it has not been found so far that TKL has the ribosome-inactivating activity.

TKL has been crystallized in space group $P2_12_12_1$ with cell dimensions a=44.7A, b=69.5A, c=180.9Å, and the diffraction data were collected to 2.7A resolution. The molecular replacement method was applied to solve this structure. In consideration of the unknown sequence of TKL, several known structures of type RIP and A and B-chains of type RIP were used respectively as the search model. The correct solution was found and verified by the method of Romit profile analysis [3]. It was found that this method is quite powerful for verification of the molecular replacement solution even in the case where the sequence of the structure to be solved is unknown and only the general laws of homology are available. The structure model, which was obtained with A- and B-chain of abrin-a [4], a type ¢ò RIP, as separate search models, shows the same spatial arrangement of the two subunits as in the abrin-a. So TKL structure possesses the features of RIP peptide folding. A refinement of the structure is in progress.

P12.04.128 IMMUNOGLOBULIN DOMAINS I-II OF NEURAL CELL ADHESION MOLECULE (NCAM). Christina Kasper, [1] Hanne Rasmussen, Jette S. Kastrup and Ingrid Kjøller Larsen, Royal Danish School of Pharmacy, Dept. of Medicinal Chemistry, DK-2100 Copenhagen, [1] Novo Nordisk A/S, DK-2880 Bagsværd

The neural cell adhesion molecule (NCAM) is a multifunctional, cell surface glycoprotein belonging to the immunoglobulin superfamily. NCAM is involved in recognition and adhesion between cells from many tissue origins, mediated via a homophilic binding mechanism. The adhesive properties of NCAM have been investigated on a putative involvement of NCAM in cancer, and the results indicate that expression of NCAM leads to a reduced cell migration and metastatic potential [1]. NCAM is also known to be involved in various morphoregulatory processes and in intracellular signal transduction underlying e.g. neurite outgrowth [2,3].

Three major isoforms are expressed in brain. Two are transmembrane, while the third is attached to the membrane via a lipid-anchor. The extracellular part of NCAM is identical in all isoforms and consists of five N-terminal immunoglobulin (Ig) domains and two membrane proximal fibronectin type three (F3) domains [2,4]. Even though it has been a well known fact for almost 20 years that NCAM binds to NCAM, the sequence(s) involved in the interaction have not yet been localized. Many different hypotheses have been put forward, ranging from single domain to multidomain interactions.

Through crystallization and structure determination of various NCAM domains we wish to increase the knowledge on NCAM structure and on the homophilic binding leading to intercellular adhesion.

NCAM IgI-II has been crystallized in space group P21, with 4 molecules/a.u. Native data have been collected at BM14 (ESRF, Grenoble) to 1.85 A.

It has not been possible to solve the structure by molecular replacement. Thus we have turned towards a HA-solution of the structure. Many HA-derivative crystals have been tested, but with consistent non-isomorphy problems. Therefore, a full MAD data set was collected to 2.8 A at BM14 (ESRF, Grenoble). The structure has been solved and refinements are in progress.

P12.04.129 STRUCTURE OF THE FMN-BINDING DOMAIN OF HUMAN CYTOCHROME P450 REDUCTASE. HPC Driessen[1], J Clapperton[1], Q Zhao[1], S Modi[4], G Smith[3], M Paine[3], PD McDonagh[4], CR Wolf[3], L-Y Lian[4], GCK Roberts[4], D Tew[2]. [1]ICRF Unit of Structural Molecular Biology, Department of Crystallography, Birkbeck College, Malet Street, London WC1E 7HX, UK; [2]Smith Kline Beecham Research, The Frythe, Welwyn, Hertfordshire AR6 9AR, UK; [3]ICRF Molecular Pharmacology Unit, Biomedical Research Centre, Ninewells Hospital and Medical School, University of Dundee, Dundee DD1 9SY, UK; [4] Centre for Mechanisms of Human Toxicity, Department of Biochemistry and Biological NMR Centre, University of Leicester, P.O. Box 138, Lancaster Road, Leicester LE1 9HN, UK.

NADPH-cytochrome P450 reductase is a key component in the cytochrome P450 monooxygenase system. The FMN-binding domain transfers electrons from the NADPH/FAD domain to cytochrome P450, which plays a pivotal role in drug and xenobiotic metabolism. The human domains have been individually expressed, and can be reconstituted to form a complex with catalytic activity in the reduction of cytochrome c and in donating electrons for cytochrome P450-dependent monooxygenase reactions. The crystal structure of the FMN-binding domain has been determined and shows high similarity to that of the bacterial flavodoxins. The residues important for FMN binding have been identified, indicating a striking conservation of the FMN binding site. The protein has an unusual surface charge distribution leading to a very strong dipole, which may be involved in docking substrates into place for electron transfer. Within the general negative surroundings of the FMN, several acidic residues have been identified by mutagenesis experiments to be important for electron transfer to cytochrome P450 2D6 and/or cytochrome c, indicating which part of the surface is likely to be involved in substrate binding.

P12.04.130 PRELIMINARY CRYSTALLOGRAPHIC STUDIES ON A PENTAFUNCTIONAL ENZYME, *AROM*. B. Lohkamp, T. Krell and J.R. Coggins, Institute of Biomedical and Life Science, University of Glasgow, Glasgow G12 8QQ, UK, J.K.F. Maclean and A.J. Lapthorn, Department of Chemistry, University of Glasgow, Glasgow G12 8QQ, UK.

In microorganisms and plants essential aromatic compounds such as folic acid and aromatic amino acids are synthesised from the precursor chorismate. Chorismate is synthesised in seven steps by the enzymes of the shikimate pathway [1]. In bacteria there are seven monofunctional enzymes, whereas in plants there are 6 enzymes with steps 3-4 catalysed by a bifunctional enzyme. In fungi the situation is very different with the central steps (2-6) of the pathway catalysed by *AROM*, a pentafunctional enzyme. This multi-enzyme is a homodimer, each chain contains ~1,600 amino acids separated into 5 domains. These domains share a high degree of sequence homology with the corresponding monofunctional enzymes present in bacteria.

We have overexpressed and purified *AROM* from several species of fungi [2], and have determined several different crystallisation conditions using sparse matrix screening. Small crystals grow after 6-10 weeks and are about 50 μm in the largest dimension. To date structures homologous to 4 of the 5 domains of *AROM* have been solved by ourselves and other groups. We hope to use these as search models to solve the structure of *AROM* by molecular replacement. The crystal structure of *AROM* will help us to understand both the functional and structural advantages of arranging enzymes together as a multi-enzyme. In addition the structure will provide a basis for the rational design of antifungal drugs.

P12.04.131 CRYSTALLOGRAPHIC ANALYSIS OF DRUG INTERACTIONS WITH HUMAN SERUM ALBUMIN. A.Bhattacharya, T.Grune, N.P.Franks and S.Curry, Biophysics Section, Blackett Laboratory, Imperial College, London SW7 2BZ, UK

Human serum albumin (HSA), the most abundant protein in the circulatory system, binds an incredible array of ligands [1]. Though its principal function is the transport of fatty acids, it is also known to sequester toxic lipophilic metabolites such as bilirubin and to limit the free plasma concentration of many drugs to less than 10% of the administered dose. Despite the affinity of HSA for this diverse array of compounds, it is known that only a small number of distinct binding locations exist. We have recently determined the crystal structure of HSA complexed with a fatty acid (myristate) [2]. We now wish to investigate the nature of drug binding sites on the protein and have solved the structures of HSA-myristate complexed with a variety of physiologically important ligands, including the anticoagulant Warfarin and Thyroxine, a hormone produced by the Thyroid gland.

For both of these ligands, the free concentration in the blood may be severely affected by binding to HSA and this can give rise to clinical complications.

Our studies reveal interplay between fatty acid and drug binding to the protein. Elucidation of the precise nature of drug interactions with HSA and HSA-fatty acid complexes will help to define important structural characteristics of protein-drug binding sites and may suggest ways to allow better control of the pharmacokinetics of drugs which bind to albumin

P12.04.132 CRYSTAL STRUCTURE AND PROPOSED AMINO ACID SEQUENCE OF A THERMOPHILIC XYLANASE FROM THE FUNGUS *PAECILOMYCES VARIOTI* BAINIER AT 1.59Å P. Rajesh Kumar, S. Eswaramoorthy, P. J. Vithayathil and M. A. Viswamitra* Department of Physics, Indian Institute of Science, Bangalore 560 012. INDIA.

We report here the amino acid sequence and the 1.59Å crystal structure of a thermophilic xylanase (PVX) from the fungus, *Paecilomyces varioti* Bainier (PvB). The enzyme has potential applications in the paper industry as an effective substitute for the toxic chlorine based chemicals. It also joins hands with the cellulase enzymes to be called as a potent air-borne and skin allergen, causing dermatitis and allergic rhinitis. The fungus also deserves special attention due to its pathogenicity on patients who possessed major post-surgical complications. It would be worthy to understand this opportunistic infection in terms of the enzymes it expresses and PVX is one such extra-cellular enzyme secreted by this organism. Of special mention is that PVX is the first enzyme from this organism whose three dimensional structure has been determined so far. The crystals belong to the orthorhombic space group, $P2_12_12_1$, with cell dimensions, a=38.7, b=54.1 & c=90.1Å, and the X-ray diffraction data was collected on an image plate with a rotating anode, at the MBU, IISc, India. The structure was solved using molecular replacement methods. Only about 10% of the amino acid sequence was available through biochemical means. The rest of the sequence was arrived using a combination of sequence and structural alignments and a good quality electron density up to 1.59Å. Sequence and structural comparisons between this enzyme and its mesophilic relatives confirm the presence of a

disulphide linkage in the structure of PVX as an obvious cause for increased thermostability. We have analysed several other physical properties and sequence related properties to figure out the reasons for increased thermostability of this class of xylanases. Details of the structure solution, analysis and the interpretation of the reasons for increased thermostability will be presented. The sequence and the structure are deposited with the SWISS-PROT and the PDB.

We thank DBT, JNCASR and INSA, India, for support, and one of us, P.R.K. thanks the CSIR, India, for a Senior Research Fellowship.

P12.04.133 THE ATOMIC RESOLUTION (1.15Å) STRUCTURE OF A NOVEL BACTERIAL ESTERASE. P.C.Bourne, M.N.Isupov and J.A.Littlechild. Departments of Chemistry and Biological Sciences, University of Exeter, Stocker Road, Exeter, EX4 4QD, UK.

The crystal structure of a novel bacterial esterase has been determined by X-ray diffraction to 1.15Å resolution. The enzyme exists as a homodimer belonging to the α/β hydrolase fold family of proteins, with a central core of eight mostly parallel β-strands surrounded by 13 α-helices. The structure was solved using Multiple Isomorphous Replacement (MIR) and averaging of diffraction data from crystals of two different morphologies. The structure has been refined isotropically with an overall R factor of 16.8% and a free R-factor of 18.6%. Refinement of anisotropic temperature factors is proceeding.

Esterase enzymes have found use in a wide variety of biotransformation reactions, catalysing the hydrolysis and transesterification reactions of a broad range of natural and unnatural substrates. This structure represents the largest hydrolase solved to atomic resolution at the present time.

P12.04.134 STRUCTURAL STUDIES ON BOVINE α-LACTALBU-MIN. E.D. Chrysina[1], K. Brew[2] and K.R. Acharya[1], [1]Department of Biology and Biochemistry, University of Bath, Claverton Down, Bath, BA2 7AY, UK, [2]University of Miami School of Medicine, USA.

The biosynthesis of lactose in the lactating mammary gland, is controlled by the activity of the lactose synthase complex. This enzyme consists of two proteins: Galactosyltransferase (GT), the catalytic protein and α-Lactalbumin (LA) the regulatory component [1]. LA is a calcium binding protein. Functional analysis using protein engineering and X-ray crystallographic techniques is in progress with the aim to investigate regions of LA that are implicated in the interaction of GT and in modulating glucose binding, the role of the highly flexible regions of LA in the interaction with GT and the functional significance of metal ion binding to LA. The gene for bovine LA has been cloned and expressed in Prof. K. Brew laboratory.

Recent site-directed mutagenesis experiments on bovine LA have probed two substructures and identified certain residues involved in LA's function [2]. Kinetic analysis of selected single site mutants show that changes in these regions have significant effects on LA's function. In the absence of a 3D structure for GT, only tentative conclusions can be made about the role of particular residues from kinetic results on these mutants. Thus, it is important to follow a 'structure-based' approach. This should enable information and conclusions to be made about the altered functional properties of a particular mutant. With this aim, a series of LA variants at regions proposed to be directly involved in LA action in LS complex were produced. The structure of LA variants along with an Apo-form of bovine LA will be presented during this meeting.

P12.04.135 2.6A STRUCTURE OF PREFERENTIALLY ACTIVE ISOFORM OF HUMAN ANTITHROMBIN. X.Y. Pei [1], R. Skinner [2], J.P. Abrahams [3], R.W. Carrell [1], [1] Structural Medicine Division, Department of Haematoloty, Cambridge Institute for Medical Research, University of Cambridge, Cambridge CB2 2XY, UK, [2] Uniniver, UK, [3] Biophysical Structural Chemistry, Leiden Institute of Chemistry, Gorlaeus Laboratories, Leiden University; Einsteinweg 55 / P.O. Box 9502 2300RA, Leiden, The Netherlands.

Here we present the crystal structure of a dimer of beta-antithrombin at 2.6A, one molecule being in the active inhibitory form (I-form) with linkage through its reactive center loop (RCL) to a second molecule in the latent conformation (L-form). Both the I- and L- forms of beta-antithrombin show clear but different changes at Asn135 when compared to alpha-antithrombin. In particular the internal orientation, with well-defined it bonding, of Asn135 in the L-form provides an explanation for the constant fraction of unglycosylation antithrombin (beta-antithrombin) present an synthesis, indicating it is a structural consequence and not an index of an inadequate glycosylation system. The only change indicating a direct reason for the higher heparin affinity of beta-antithrombin is a shift of one of the primer binding residues, Arg129, to an optional orientation. The likely reason for the overall increase in affinity is the greater flexibility of the hD-s2A loop containing Asn135) that undergoes conformational rearrangement on the binding of heparin. The result allowed us to study the physiology of beta-antithrombin in the blood circulation and to design phamecoutic drug for the thromboembolic disease.

P12.04.136 ATOMIC STRUCTURES OF INORGANIC PYROPHOSPHATASE COMPLEXED WITH CALCIUM AND CALCIUM-PYROPHOSPHATE. V.R. Samygina[1], A.N. Popov[2], V.S. Lamzin[2], N.N. Vorobeva [3], S.A. Kurilova [3], T.I. Nazarova [3], S.M. Avaeva [3], [1]Institute of Crystallography, Russian Academy of Sciences, Leninsky pr. 59, Moscow 117333, Russia, [2]Europen Molecular Biology Laboratory (EMBL), c/o DESY, Notkestrasse 85, 22603 Hamburg, Germany, [3]Belozersky Institute of Physico-Chemical Biology, Moscow State University , Moscow 119899, Russia.

The refined atomic resolution structures of E.coli inorganic pyrophosphatase (PPase) complexed with calcium and calcium-pyrophosphate (CaPPi) permit us to suggest a possible inhibiting and functioning enzyme mechanism. PPase catalyzes the cleavage of the phosphoanhydride bond in molecule of inorganic pyrophosphate, which is product of many biosynthetic reactions. Thus PPase controls the level of pyrophosphate in the cell. Divalent metal ions , where magnesium ions are most effective, are required for the activity of PPase. Four Mg^{2+} ions take part in hydrolysis : two of them are bound to the enzyme with different affinity before pyrophosphate binding, and the other two are bound in the presence of substrate. Calcium acts as an inhibitor.

The new conditions under which E.coli PPase crystallises have been determined. Using special cryogenic technique and synchrotron radiation diffraction data sets were collected up to 1.2 Å for complexes with Ca^{2+} ions and CaPPi, whereas all previous structures of E.coli PPase have been determined at resolution not higher than 1.9 Å .The crystals of complex with Ca^{2+} have been

obtained using the co-crystallisation, the CaPPi complex have been obtained by co-crystallisation together with additional soaking. The binding sites for substrate molecule and metal ions have been identified on the difference electron density map. The changing of positions of several functional groups and some parts of a polypeptide chain were observed after Ca^{2+} and substrate binding. It explains well known inhibiting effect of Ca^{2+} binding and allows to elucidate some details of catalysis mechanism.

P12.04.137 STRUCTURE REFINEMENT OF FMN-BINDING PROTEIN AT ULTRA-HIGH RESOLUTION. K. Suto, N. Shibata, Y. Morimoto, N. Yasuoka. Department of Life Science, Faculty of Science, Himeji Institute of Technology, 1475-2, Kanadechi, Kamigori, Ako-gun, Hyogo 678-1297, Japan

Crystal of FMN-binding protein (FMN-bp) diffract up to 0.84 Å resolution at 100K, and diffract up to 1.10 Å at room temperature. The data were collected at SPring-8, Japan. Assignments of the atom species have been easily carried out, judging from the peak height on electron density, for example, in the case of the O, N, C atoms at side chain of aspartic acid and / or threonine. Double conformers were found and located in the main chain atoms of five residues as well as the side chains of 9 residues. Some peaks in the difference Fourier map could be assigned for hydrogen atoms including in hydrogen bonding.

FMN-bp from *Desulfovibrio vulgaris* Miyazaki F is the smallest flavoprotein and has 122 residues and one FMN cofactor in a monomer [1]. The purified sample was crystallized by the hanging-drop vapor diffusion method. Addition of 20% glycerol or 30% MPD to crystallization condition dramatically improved quality of the crystals. Initial phases were determined by the MIR method. FMN-bp exists as a dimer in an asymmetric unit, and two FMNs are held in cleft between two monomers. The high resolution data were measured using a Rigaku R-AXIS IV at BL44B2, SPring-8 (wavelength 0.700 Å). The refinement was carried out using XPLOR for preliminary stage, and then using SHELX-97. *R*work and *R*free with isotropic refinement were decreased to 0.152 and 0.181 for 8.0 - 1.20 Å. Structure refinement with anisotropic temperature factors with higher resolution data is now underway, and the result will be reported.

P12.04.138 A 1.1A CRYSTAL STRUCTURE OF THE MOLYBDATE BOUND PERIPLASMIC BINDING PROTEIN MODA2. Lalji Kanbi [1], David Lawson, Clare Williams, Richard Pau [2], Samar Hasnain [1], [1] CLRC Daresbury Laboratory, Warrington WA4 4AD, UK & Biomolecular Science, De Montfort University, Leicester LE1 9BH, [2] Nitrogen Fixation Laboratory, John Innes Centre, Norwich, NR4 7UH, UK

Azotobacter vinelandii is the only bacterium known so far which possesses two periplasmic molybdate binding proteins which are denoted ModA1 and ModA2. Both are components of high affinity transporters, with a binding pocket highly specific for the larger oxydianions molybdate and tungstate. The molybdenum is primarily utilised in the cofactors of oxidoreductases (eg. nitrogenase and dimethyl sulfoxide reductase). Recently, we have reported the structure of ModA2 in its tungstate bound form (Lawson et al. 1998), where the primary sequence was determined directly from electron density maps. Here we report an independent ab initio [italics] structure determination using isomorphous data from the molybdate and the tungstate bound forms extending to resolutions of 1.2 A and 1.1 A respectively. Maps calculated from Single Isomorphous Replacement Anomalous Scattering phases are of high quality. The resultant crystal structure will provide an independent determination of the primary structure. Anisotropic refinement with SHELX at 1.1 A resolution is currently in progress.

The results of this work will be presented.

Lawson, D.M., et al(1998). Ligand size is a major determinant of specificity in periplasmic oxyanion-binding proteins: the 1.2 A resolution crystal structure of Azotobacter vinelandii ModA.Structure,6;1529-1539

P12.04.139 MULTIPLE CONFORMATIONS OF CATALYTIC SER AND HIS IN ACETYLXYLAN ESTERASE AT 0.90A AND 85K. Debashis Ghosh[1,2], Mark Sawicki[2], Mary Erman[1], Daniel R Weeks[1], Puloma Lala[2], Walter Pangborn[1], Daniel J Thiel[3], Hans Jörnvall[4], Jaime Eyzaguirre[5] and Naiyin Li[1]. [1]Hauptman-Woodward Institute, Buffalo, New York. [2]Roswell-Park Cancer Institute, Buffalo, New York. [3]Cornell High Energy Synchrotron Source, Ithaca, New York. [4]Karolinska Institutet, Stockholm, Sweden. [5]Pontificia Universidad Catolica de Chile, Santiago, Chile.

Acetylxylan esterase (AXE II; 207 amino acids) from *Penicillium pupurogenum* has substrate specificities towards acetyl esters of β-D-xylopyranoside residues in a xylan chain and belongs to a new class of α/β hydrolases. The crystal structure of AXE II has been determined by isomorphous difference and anomalous scattering from iodine atoms introduced by iodination of the crystal. The structure of the iodinated complex of the enzyme at 1.80A resolution reveals the formation of iodotyrosines at two locations of the polypeptide. The native structure has been refined to 0.90A and 1.10A resolutions with the data collected at the Cornell High Energy Synchrotron Source at 85K and 295K, respectively. The tertiary structure consists of a doubly-wound α/β sandwich, having a central six-stranded parallel β-sheet flanked by two parallel α-helices on each side. The catalytic residues Ser 90-His 187-Asp 175 are located at the C-terminal end of the sheet, a highly exposed region of the molecule. The serine and histidine sidechains in the 295K structure shows the frequently observed conformation in which Ser 90 sidechain is *trans* and the hydroxyl group is in the plane of the imidazole ring of His 187. However, the structure at 85K displays an additional conformation in which Ser 90 sidechain is *cis*, away from the imidazole plane of the histidine residue. The His 187 sidechain forms a hydrogen bond with a sulfate ion and adopts an altered conformation to accommodate it. The only other known hydrolase that has a similar tertiary structure is *Fusarium solani* cutinase. The exposed nature of the catalytic triad suggests that AXE II is a pure esterase.

P12.04.140 STUDIES ON THE THREE-DIMENSIONAL STRUCTURES OF PHYCOBILI-PROTEINS. J.P. Zhang, T. Jiang, W.R. Chang, J.Y. Liu, D.C. Liang, National Laboratory of Biomacromolecules, Institute of Biophysics, Academia Sinica, Beijing 100101, China

The phycobiliproteins in algae can be divided into three main classes: phycoerythrins (PE), phycocyanins (PC) and allophycocyanins (APC) according to their visible light absorption properties. Energy transfer proceeds successively in the direction of PE→PC→APC→chlorophyll with an overall efficiency of almost 100%.

The structure of R-Phycoerythrin (R-PE) from *Polysiphonia urceolata* was determined by MIR method and refined at 1.9Å resolution. The crystals belong to space group R3 with unit cell dimensions of a=b=189.8Å, c=60.1Å. The subunit composition of R-PE is $(\alpha_2\beta_2)_3\gamma$. The interactions between chromophores and protein are observed in high resolution. The four phycoerythrobilin chromophores α84, α140a, β84 and β155 in an (αβ) unit are each covalently bound to a cysteine residue through ring A. The phycourobilin chromophore is bound to a cysteine β50 by ring A and bound to cysteine β61 by ring D. The ring A and ring D of phycourobilin deviate from the conjugate plane formed by ring B and ring C and the four rings form a boat-

shaped structure. R-PE contains a 34K Da γ subunit that is assumed to lie in the central channel of the molecular disc $(\alpha_2\beta_2)_3$. The energy transfer and the interactions between protein residues and chromophores are discussed.

R-phycocyanin (R-PC) from *Polysiphonia urceolata* has been isolated and crystallized. Diffraction data were collected up to 2.4Å resolution. The structure determination by molecular replacement method is in progress.

Allophycocyanin (APC) from red alga *Porphyra yezoensis* has been crystallized in three crystal forms. The space group of form 3 is R32 with cell dimensions a=b=105.3, c=189.4Å and one αβ unit in the asymmetric unit. Low-resolution structure of APC was solved by molecular replacement method and the structure refinement at 2.2Å resolution is in progress.

P12.04.141 PROTEIN CARBOHYDRATE INTERACTIONS AT ATOMIC RESOLUTION. James H. Naismith, Davina N. Moothoo, David A.R. Sanders [1], Andy Howard [2], Paul Faulder, Rachel B Nuttall, James R. Raftery, John R. Helliwell [3], 1. Biomolecular Sciences, St Andews University, Scotland, 2. Advanced Photon Source, Argonne, Illinois, USA, 3. Chemistry Dept, University of Manchester, M13 9PL, UK

We have been seeking to probe carbohydrate interaction by structural methods to provide a molecular rationale for binding affinities observed by calorimetery. This is vitally important if modelling approaches for protein carbohydrate interactions are to progress. Currently even the most sophisticated of these approaches fails to predict either the orientation or affinity of carbohydrate binding. We have chosen to study the lectin concanavalin A. It is an ideal model system. Its protein carbohydrate interactions are well characterised by calorimetery, it is readily available and we are able to obtain complexes with many different carbohydrates. As part of this program we have now collected data at cryotemperature at the APS IMCA undulator beamline, and with a CCD detector, to 1.20 Å resolution from crystals of the concanavalin A Man alpha 1-2 Man complex. The structure shows in atomic detail the concanavalin A disaccharide interaction unequaled to our knowledge by any other protein carbohydrate complex.

P12.04.142 THE STRUCTURE OF CASPASE 8 AT ATOMIC RESOLUTION. William Watt, Keith D. Watenpaugh Alfredo G. Tomasselli, Kenneth A. Koeplinger, Ana M. Mildner, Robert L. Heinrikson Structural, Analytical and Medicinal Chemistry, Pharmacia and Upjohn, Kalamazoo, Michigan Protein Science, Pharmacia and Upjohn, Kalamazoo, Michigan

Caspase 8 is a cysteine proteinase that is considered to be a prime initiator in a cascade of events leading to proteolytic activation of caspase 3, the executioner of programmed cell death, or apoptosis. We have cloned and expressed an inactive, precursor form of human caspase 8 that was produced in high yield as inclusion bodies in Escherichia coli. The protein was solubilized and refolded to give an inactive, single-chain precursor which, upon concentration, auto activated to yield authentic and highly active caspase 8. The recovery of pure enzyme was 10 mg/liter of bacterial culture. The structure of the caspase 8 covalently linked to Ac-IETD-aldehyde has been solved by x-ray crystallography and refined using a 1.2 Å dataset (a=b=62.4Å, c=129.25Å, space group $P3_121$, RF=0.15 for the refined structure). The asymmetric unit consists of a heterodimer with a crystallographic dyad generating the biologically active tetramer. While the basic protein fold is very similar to that of caspase 1 and caspase 3, the substrate binding region has significant differences which explain the specificity of caspase 8. The Ac-IETD-aldehyde is bound covalently to the catalytic cysteine with the aspartic acid buried in the protein. The structure forms the basis of an active structure-based drug design project.

P12.04.143 NEUTRON-LAUE & ATOMIC RESOLUTION X-RAY ANALYSIS OF ENDOTHIAPEPSIN. J.B. Cooper and P.T. Erskine. School of Biological Sciences, University of Southampton, Southampton, SO16 7PX, UK, and D.A.A. Myles. Institut Laue-Langevin and EMBL, Grenoble, France.

Aspartic proteinases are a family of enzymes involved in a number of important physiological and pathological processes. Until now, no aspartic proteinase has been subjected to a successful neutron diffraction analysis due to the limited size of the crystals. However, the recent development of the neutron-Laue technique at ILL (Grenoble), has allowed us to collect neutron data to 2.2 Å on a complex of endothiapepsin with a transition state analogue. Current proposals for the catalytic mechanism of aspartic proteinases are largely based on X-ray structures of inhibitor complexes but these proposed mechanisms differ in the assignment of protonation states to the catalytic groups and intermediates during the reaction. Our objective is to define the positions of the protons at the active site by exhaustive refinement using the neutron data. In line with work on serine proteinases where neutron diffraction has provided some of the most definitive data on the catalytic mechanism, we expect that our work will have a greater significance for studies of the aspartic proteinase enzymes where mechanistic studies by other techniques have been largely inconclusive.

The co-crystals of endothiapepsin with the inhibitor H-261 are monoclinic ($P2_1$) and have unit cell dimensions of a = 43.1 Å, b = 76.1 Å, c = 43.0 Å, β = 97.0°. A large deuterated crystal was mounted on the LADI instrument at ILL and has so far yielded neutron data to 2.2 Å. The data have an R-merge of 13.7 %, a completeness of 81% and mean multiplicity of 2.0. In parallel we have obtained X-ray data to 1.1 Å resolution from a frozen crystal of the same complex at beam line BW7B at DESY (Hamburg). These data have an R-merge of 12.5 %, a completeness of 99.8 % and a mean multiplicity of 3.7. Least-squares refinement of the structure with these datasets is in progress using SHELX-97 (G.M. Sheldrick).

P12.04.144 CRYSTAL STRUCTURE OF THE CATALYTIC DOMAIN OF CHITINASE A1 FROM *BACILLUS CIRCULANS* WL-12. T. Matsumoto, T. Nonaka, Y. Mitsui, Department of BioEngineering, Nagaoka University of Technology, Kamitomioka, Nagaoka, Niigata 940-2188, Japan, H. Katohda, M. Hashimoto, T. Watanabe, Department of Agricultural Chemistry, Faculty of Agriculture, Niigata University, Ikarashi-2, Niigata, Niigata 950-2181, Japan

Chitinases are enzymes for the hydrolysis of the chitin, which is the homopolymer of *N*-acetylglucosamine. *Bacillus circulans* WL-12 secretes at least six kinds of chitinases into the culture medium. Chitinase A1, the main chitinase of this bacterium, consists of three kinds of domains (a catalytic domain, two type III homology units of fibronectin, and C-terminal short segment). The catalytic domain of chitinase A1 is composed of 419 amino acid residues (Mr. 45489). It was crystallized at 20°C by vapor diffusion method using polyethylene glycol as a precipitant. Structural analysis was attempted by a molecular replacement method. A molecular model of the catalytic domain of chitinase A1 based on the three dimensional structure of chitinase A from *Serratia marcescens* was constructed by homology modeling technique. It was possible to determine the orientation of the catalytic domain of chitinase A1 from a series of rotation search. However, there were many areas where it was difficult even to interpret the electron density distribution for the main chain, and accordingly the refinement of the crystal structure failed. However, interpretation of the electron density map became possible after the phases were expanded and improved using the X-ray diffraction data up to 1.5Å resolution. Currently we are refining the three dimensional structure, adding the anisotropic

displacement parameters to the calculation, using the diffraction data up to 1.13Å resolution. As a result of the refinement at an atomic resolution, it became possible to identify the orientation of the imidazole ring of the histidine residues and to distinguish the nitrogen atom from the oxygen atom in the side chain of the asparagine and glutamine residues.

P12.04.145 THE HISTONE OCTAMER OF THE NUCLEOSOME CORE PARTICLE IN KCL/PHOSPHATE: STRUCTURE TO 2.15Å RESOLUTION IN SPACE GROUP $P6_5$. J.P. Baldwin, S.J. Lambert, A.J. Reid, and M.J. Donovan, Beckman Laboratory, School of Biomolecular Sciences, Liverpool John Moores University, Byrom St., Liverpool L3 3AF, UK, and J.M. Nicholson, Daresbury Laboratory, Warrington, Cheshire WA4 4AD, UK, and L. Chantalat, Laboratoire de Crystallographie Macromoleculaire, Institut de Biologie Structurale, 41 Avenue des Martyrs, 38027 Grenoble 1, Cedex, France.

Intact histone-core octamers of the nucleosome crystallise in space group $P6_5$ using 2M KCl and 1.35M phosphate [1, 2]. The octamers pack, one per unit cell, in a left-handed helical arrangement with six octamers per turn in a c-axes repeat of 102.6Å, providing a useful model for nucleosome packing in chromatin higher-order structure. The $P6_5$-octamer structure has been refined to 2.15Å resolution and 70% of the total amino acids are conserved with a mean positional difference of 0.5Å compared with the octamer in the nucleosome core particle at 2.8Å resolution [3], with a near-identical distribution of temperature factors, between 20 and 60Å^2. A further 6% of the total amino acids are assigned in the $P6_5$ structure and are positioned differently from those in the nucleosome core particle with temprature factors between 20 and 100Å^2. N-terminal basic domains accounting for the remaining 24% of the total amino acids, are disordered as are 20% of those in the nucleosome core particle. 540 highly-ordered water molecules are clearly assigned with many H_2O - H_2O hydrogen bonds. They form sheet-like structures over regions of the surface of the octamer, the highly basic cage at the centre of the octamer and in channels leading from the central cage to the surface of the octamer. Several phosphate groups from the crystallisation buffer have been assigned on the outside of the octamer. The role of the two C-terminal α helices of histones H2B in binding DNA in the condensed chromatin higher-order structure and the possible role in the movement of octamers around RNA polymerase in transcription is discussed.

P12.04.146 0.9Å STRUCTURE OF A KUNITZ DOMAIN FROM THE A-3 CHAIN OF HUMAN TYPE VI COLLAGEN B. Arnoux, M.C. Vaney, A. Ducruix [1], K. Norris, F. Norris [2], [1] Laboratoire d'Enzymologie et Biochimie Structurales, CNRS, 91198 Gif sur Yvette, France, [2] Health Care Discovery, Novo Nordisk A/S, DK-2820 Gentofte, Denmark

The C-terminal Kunitz-type domain from the alpha-3 chain of human type VI collagen (C5), a single 58 amino acid residue chain with three disulfide bridges, was cloned, expressed and crystallized in a monoclinic form, space group P21, with a=25.2Å, b=37.7Å, c=28.5Å and b=109.3°. A previous refinement was done at 1.2 Å at room temperature (R=13.6%, between 7 and 1.2 Å) with anisotropic temperature factors [1] and the model subjected to normal mode calculation. The results indicate fluctuations with a large anisotropy since the total fluctuations are close to the largest component of the principal axes of fluctuations. The anisotropy in the crystal fluctuations are less marked. However a good correlation between the theoretical fluctuations and the X-ray profiles are observed. Besides this crystal structure at room temperature, two NMR structures of C5, also at room temperature were published [2,3]. To decouple static and dynamic disorder, a new data set at low temperature was collected at the EMBL Hamburg outstation. The anisotropic refinement of the protein-water-ion model at 0.9Å resolution using the program SHELXL-97 is in progress. Ultrahigh resolution data provides a solid base for getting a better insights into the hydration shells of proteins. The comparison of this low-temperature model with the previous ones (room temperature, NMR) will lead to a complete description of the molecule, including domain movements and relative flexibility of surface loops using normal mode analysis. The localization of ion and water molecules will also be discussed in term of folding.

The low-temperature (100K) crystal structures of myoglobin and leg hemoglobin in the deoxy, met and CO liganded states have been refined at atomic resolution (0.9 – 1.1Å). Comparison to the corresponding room temperature structures shows significant differences in the conformations due to the cooling. Taking the example of CO myoglobin, substantial changes are observed in the overall conformation and in the interactions between the bound ligand and its immediate environment. The cooling in particular changes the Fe-C-O binding geometry, the distance of the heme iron from the plane defined by four pyrrol nitrogens, and the distances between the CO oxygen and distal residues. Furthemore, the bondlength between the Fe and proximal histidine, and the conformation of the porphyrin are affected. On the other hand, the number of sites of the distal histidine is not affected by cooling, neither in deoxy nor in CO myoglobin. Despite the cryo-induced conformational changes, the low-temperature structures provide information on the interaction between the heme group and the protein matrix, which is relevant for an interpretation of the structure-function relationships in heme proteins under physiological conditions.

P12.04.149 THE 0.97 Å RESOLUTION STRUCTURE OF CYTOCHROME C-553 FROM *BACILLUS PASTEURII*. STRUCTURAL AND FUNCTIONAL ANALYSIS. W. R. Rypniewski[@], S. Benini[@], A. Gonzalez[@], K. S. Wilson[£], S. Ciurli[$]. [@]EMBL c/o DESY Notkestraße 85 D-22603 Hamburg, Germany [£]Dept. of Chemistry, York University Heslington YO1 5DD, UK, [$]Inst. di Chimica Agraria, Bologna University, Viale Berti Pichat 10 I-40127.

The gram-positive, highly ureolytic *B.pasteurii* is an obligate aerobe and facultative alkaliphile that grows optimally at pH 9.2 in the presence of high amounts of NH_4^+ salts or urea. The cytochromes from alkaliphilic bacteria are characterised by distinctly low reduction potentials, a feature that has been proposed to facilitate electron transfer to the membrane bound oxidase in the presence of the large negative membrane potential

associated with the alkaline growth medium. Cytochrome c-553 from *B. pasteurii* has been extensively studied using ^{1}H NMR and direct cyclic voltammetry [1]. The NMR spectra indicate a His-Met axial coordination of the low spin (S=1/2) heme iron. The pH dependence of the NMR signals display a ionisation step with pK_o=5.7. The pH dependence of the reduction potential determined by cyclic voltammetry indicates potentials for the protonated and deprotonated forms of +71 mV and +58 mV, respectively. The thermodynamic and spectroscopic data indicate a large solvent-derived entropic effect as the main cause for the low reduction potential. The protein has been crystallised and data have been collected to 0.97 Å [2]. The ultra high resolution allowed us to solve the structure by a completely automated procedure using ARP and REFMAC. Refinement using SHELXL gave a final R_{factor}=11.5%. Cytochrome c-553 is a small heme protein (71 residues) with a very exposed heme. The high resolution provided the most accurate analysis of a heme containing protein to date. Comparison of different cytochromes belonging to the c class has been used to analyse the relationship between the folding, accessibility of the heme to the solvent and the reduction parameters [3].

P12.04.150 CRYSTAL STRUCTURE OF *E.Coli* MurD/UMA/ AMPPCP COMPLEX AT 1.5 Å RESOLUTION. N.Y. Chirgadze, G. M. Birch, L. C. Blaszczak, S.L.Briggs, D.K. Clawson, N. G. Halligan, J. E. Mcgee, S. Sigmund, M. C. Smith, R.W. Schevitz. Lilly Research Laboratories, Eli Lilly & Company, Indianapolis, IN 46285, USA.

The crystal structure of His-tagged *E.coli* UDP-N-acetylmuramoyl-L-alanine-glutamate:D-glutamate (MurD) in a complex with UDP-MurNAc-L-Ala (UMA) and adenosine 5'-[β,γ-methylene] triphosphate (AMPPCP), a non-hydrolyzable ATP analog, has been determined at 1.5 Å resolution using X-ray crystallography to aid in the design of MurD inhibitors. MurD, essential to cell wall containing bacteria, is an attractive target for drug development. Crystals of the complex were obtained from 20% MME PEG5000, 0.2M LiCl, and 0.1M MES buffer at pH=6.1, under nitrogen, by the vapor diffusion technique at 20°C. $MgCl_2$, UMA, and AMPPCP were present at 1.5 eq. Crystals belong to the orthorhombic space group, $P2_12_12_1$, with unit cell parameters *a*=49.0 Å, *b*=84.9 Å, *c*=115.3 Å, with one molecule per asymmetric unit. Diffraction data were collected on a synchrotron beam line ID-17 at the Advanced Photon Source at 100K. The phase problem was solved by molecular replacement using the 1UAG[1] structure as a search model. The current crystallographic R-value is 21.6% (R_{free}=24.3%). Two loops, 221-225 and 241-244 not resolved in 1UAG structure, are well defined in our electron density. In contrast to 1UAG, no oxidation of Cys208, Cys227 or carbamylation of Lys198 was observed. Both UMA and AMPPCP are well resolved in the electron density. The UMA uridine moiety has a different conformation in our structure from 1UAG, as a result of a small shift of the N-terminal domain. AMPPCP binds between the middle and C-terminal domains causing the latter to move with a maximum displacement in C_α atoms of 5 Å. The C-terminal domain moves as a rigid body pivoting around residue Gly298 and closing the ATP binding cleft. AMPPCP binding is characterized mostly by electrostatic (Lys115, Arg302 and Lys319) and hydrogen bond interactions, both directly with protein and through structural water molecules. In addition, the crystal structure of a complex with a transition state analog-like inhibitor was determined at 2.6 Å resolution. The binding mode of the inhibitor mimics in part the position of phosphate and MurNAc portion of UMA, and reveals the glutamic acid binding site.

P13.04.001 STRUCTURE OF FORMYLTETRA-HYDROFOLATE SYNTHETASE FROM *CLOSTRIDIUM THERMOACETICUM* DETERMINED BY MAD. Lukasz Lebioda, Ramin Radfar, Ronald Shin, J. D. Odom, and R. Bruce Dunlap, Department of Chemistry and Biochemistry, University of South Carolina, Columbia, SC 29208,USA, Charles R. Lovell, Department of Biological Sciences, University of South Carolina, USA, Wladek Minor, Department of Molecular Pharmacology and Biophysics, University of Virginia, USA, and George M. Sheldrick, Institut fur Anorganische Chemie, Universitat Gottingen, Germany

The tetrahydrofolate (THF)-mediated transfer of one-carbon units is crucial to purine and pyrimidine biosynthesis. One of the key THF mediated reactions is the ATP-dependent activation of formate by formyltetrahydrofolate synthetase (FTHFS) (EC 6.3.4.3). In *Clostridium thermoaceticum,* FTHFS exist as a homotetramer of 240 kDa and is activated by monovalent cations (ammonium or potassium).

A plasmid coding for FTHFS was incorporated into the methionine auxotroph *E. coli* strain DL-41 and overexpressed in media containing selenomethionine. The selenomethionyl FTHFS exhibited similar kinetic behavior to the wild type enzyme, however, it did differ from the wild type in that the enzyme retained 100% of its activity when Ca^{2+} was substituted for Mg^{2+}, as opposed to 70% for the wild type.

X-ray diffraction data were collected at –160 ºC at the Structural Biology Center beamline at the Argonne synchrotron source using four wavelengths. The positions of 28 sites of Se atoms were established using the SHELX-M software. Experimental phases were obtained using the MLPHARE software and optimized using solvent flattening and histogram matching with the DM program from the CCP4 system.

The subunit is built of two domains, each of them belonging to the αβ class. The enzyme has an unusual quaternary structure with the four subunits being approximately in one plane, forming an arrangement with the shape of the letter "X". There are numerous intersubunit contacts at each of the "four corners". The site of monovalent cation binding was established by exchange of ammonium sulfate with cesium sulfate.

P13.04.002 TRAPPING THE CO^{3+}-INSULIN STATE BY SEMI-TIME-RESOLVED CRYO-CRYSTALLO-GRAPHY. L.C. Perkins and F.C.F. Körber, School of Biomolecular Sciences, Liverpool John Moores University, Byrom Street, Liverpool L3 3AF, UK, and J.M. Nicholson, PX-Facility Group, SR Department, CCLRC-Daresbury Laboratory, Daresbury, Warrington WA4 4AD, UK.

Thomas and Wollmer [1] have shown spectroscopically that hexameric insulin which is co-ordinated to cobalt ions instead of zinc can undergo a variety of structural transitions. We have been able to initiate one of these transitions, triggered by the oxidation of Co^{2+} to Co^{3+} in the crystal through the addition of hydrogen peroxide. Although there is a definite colour change in crystals subjected to this treatment, X-ray crystallographic structure determinations of the end-states at room temperature indicate that the metal ions are predominantly octahedrally co-ordinated and the structures are virtually identical [2]. As it is obvious that in the mother liquor the hydrogen peroxide is rapidly decomposed, we concluded that the metal ion in the end state had reverted to Co(II).

In order to capture the Co(III)-insulin state, crystals mounted on hairloops were flash-frozen at various times after initiating the transition, and almost complete diffraction data sets were recorded to a resolution of 2.4 Å. Currently, the intermediate structures are being refined and compared with a 1.2 Å cryo-cooled Co(II)-insulin structure [3]. Present results indicate that, after being subjected to hydrogen peroxide for 5 minutes, the Co is tetrahedrally co-ordinated. His B10 and the adjacent section of the insulin B-chain seem to have undergone a small shift. Very high B-values for the Co-ion suggest that the Co may be involved in the decomposition of the peroxide.

P13.04.003 PHOTOLYSIS AND GEMINATE REBINDING OF CO HEMOGLOBIN STUDIED BY SINGLE-BUNCH LAUE DIFFRACTION. S. Adachi, S.-Y. Park, T. Iizuka [1], H. Morimoto [2], T. Ursby [3], D. Bourgeois, M. Wulff [4], V. Srajer, T.-Y. Teng, Z. Ren, C. Pradervand, W. Schildkamp, K. Moffat [5], [1] The Institute of Physical and Chemical Research (RIKEN), Harima Institute, Sayo, Hyogo, Japan, [2] Department of Biophysical Engineering, Osaka University, Toyonaka, Osaka, Japan, [3] Department of Molecular Biophysics, Lund University, Lund, Sweden, [4] European Synchrotron Radiation Facility (ESRF), Grenoble Cedex, France, [5] Department of Biochemistry and Molecular Biology and the Consortium for Advanced Radiation Sources, The University of Chicago, Chicago, IL, USA

The crystal of T-state HbACO (Mg-Fe hybrid HbACO) was photolyzed by nanosecond YAG-laser-pumped dye laser, and 150 ps x-ray pulses emitted by a single electron bunch of ESRF storage ring [1,2] were used to obtain Laue diffraction data with nanosecond time resolution during subsequent CO rebinding process at ESRF BL3/ID9. The Laue diffraction dataset at time delay of 2 ns between laser and x-ray was refined by X-PLOR and a possible docking site of CO in the heme pocket of b2 subunit of HbA was found in the 2Fo-Fc map. The site was similar to the docking site which was found in myoglobin. These time-resolved experiments reveal the structures of hemoglobin photoproducts, provide a structural foundation to spectroscopic results and molecular dynamics calculations.

P13.04.004 HUMAN CERULOPLASMIN: CRYSTALLOGRAPHIC STUDY OF THE SUBSTRATE AND INHIBITOR BINDING SITES V.Zaitsev [1], I.Zaitseva [1], M.Papiz [1] and P.Lindley [2] [1] CCLRC Daresbury Laboratory, Warrington, Cheshire, WA4 4AD, UK [2] ESRF, BP-220, F-38043 Grenoble Cedex, France

Ceruloplasmin is a multi-copper oxidase,which contains over 60% of the copper present in plasma. It is an acute phase reactant that exhibits a 2- to 3-fold increase over the normal concentration of 300 µg/ml in adult plasma. However, the precise physiological role(s) of ceruloplasmin has been the subject of intensive debate and it is likely that the enzyme has a multi-functional role including iron oxidase activity and the oxidation of biogenic amines [1,2]. The three-dimensional X-ray structure of the human enzyme shows that the molecule is comprised of 6 cupredoxin-type domains arranged in a triangular array [2]. There are 6 integral copper atoms per molecule (mononuclear sites in domains 2,4 and 6 and a trinuclear site between domains 1 and 6) and two labile sites with roughly 50% occupancy . Further structural studies on binding of metal cations by the enzyme indicated a putative mechanism for ferroxidase activity [3]. Medium-resolution X-ray studies (3.0-3.5 Å) have recently been undertaken, which located the binding sites for an inhibitor (azide) and various substrates (aromatic diamines, biogenic amines and d-lysergic acid ethylamide, LSD). The binding site of the azide moiety is topologically equvalent to one of the sites reported for ascorbate oxidase [4]. However, there are two distinct binding sites for amine substrates; aromatic diamines bind on the bottom of domain 4 remote from the mononuclear copper site, whereas the biogenic amines typified by serotonin, epinephrine, norepinephrine and dopa bind in close vicinity to that utilized by cations in domain 6 and close to the mononuclear copper. These binding sites are discussed in terms of possible oxidative mechanisms [5].

P13.04.006 CRYSTAL STRUCTURE OF CCDB, A TOPOISOMAERASE POISON FROM E. COLI. R. Loris, M.-H. Dao-Thi, L. Wyns, Vrije Universiteit Brussel, Paardenstraat 65, B-1640 Sint-Genesius-Rode, Belgium.

The crystal structure of CcdB, a protein that poisons E. coli gyrase, was determined in three crystal forms. The protein consists of a 5-stranded anti-parallel (-pleated sheet followed by a C-terminal (-helix. In one of the loops of the sheet, a second small 3-stranded anti-parallel (-sheet is inserted that sticks out of the molecule as a wing. This wing contains the LysC proteolytic cleavage site that is protected by CcdA and therefore forms a likely CcdA recognition site. A dimer is formed by sheet extension and by extensive hydrophobic contacts involving three of the five methionines and the C-terminus of the (-helix. The surface of the dimer on the side of the (-helix is overall negatively charged, while the opposite side as well as the wing sheet is dominated by positive charges. We propose that the CcdB dimer binds into the central hole of the 59 kD N-terminal fragment of GyrA, after disruption of the head dimer interface of GyrA.

P13.04.007 CRYSTALLIZATION OF *CRITHIDIA FASCICULATA* TRYPAREDOXIN. Magnus S. Alphey[1], Gordon A. Leonard[2], David G. Gourley[1], Emmanuel Tetaud[1], Alan H. Fairlamb[1] and William N. Hunter[1]. [1] Department of Biochemistry, Wellcome Trust Building, University of Dundee, Dundee, DD1 5EH, Scotland, UK. [2] Joint Structural Biology Group, ESRF, BP 220, F38043, Grenoble, CEDEX, France.

Recombinant tryparedoxin, a thioredoxin homologue from *Crithidia fasciculata* has been purified from an *Escherichia coli* expression system and used in crystallization trials. Orthorhombic needles in space group $P2_12_12_1$, with unit cell dimensions of a = 38.63, b = 51.47, and c = 73.41 Å have been obtained. The crystals present a monomer of approximate molecular mass 16 kDa in the asymmetric unit and diffract to high resolution using synchrotron radiation. Structure determination will further understanding of the role tryparedoxin plays in regulating oxidative stress in parasitic trypanosomatids.

P13.04.009 X-RAY STRUCTURAL STUDIES OF THE CYTOPLASMIC MOLYBDATE BINDING PROTEIN MODG L. Delarbre, C.E.M. Williams, D.J. White, L.A. Mitchenall, R.N. Pau and D.M. Lawson, Nitrogen Fixation Laboratory, John Innes Centre, Norwich NR4 7UH, UK.

A. vinelandii ModG belongs to a novel family of intracellular molybdate-binding proteins that also bind tungstate but not sulfate, and are described as molbindins [1]. They appear to be involved in intracellular molybdenum homeostasis, and in diazotrophs such as *A. vinelandii*, may have a role in nitrogenase cofactor biosynthesis. The simplest molbindin identified to date is the Mop protein from *H. influenzae*, which is a homotetramer of 7kDa subunits. ModG however, has a subunit molecular weight of 14kDa which is made up of a tandem repeat of Mop-like sequences [2]. We have solved the structure of the ligand-bound form of ModG at 2.2 Å resolution by MAD phasing on tungstate. Moreover, we anticipate that by a combination of MAD phasing on a gold derivative and Molecular Replacement using the ligand-bound structure, we will be able to solve the apo structure. ModG is comprised almost entirely of β-strands and makes use of positively charged amino acids to bind its ligand, in sharp contrast to the periplasmic receptor (ModA), which relies on local dipoles provided by α-helices to dissipate the negative charge [3]. Through site-directed mutagenesis, we aim to probe the specificity of these binding sites. Furthermore, through comparison with the apo form we will be able to characterise the conformational changes associated with ligand binding.

P13.04.010 TOPOLOGICAL STRUCTURE OF ARTIFICIAL INHIBITORS DETERMINED BY X-RAY CRYSTALLOGRAPHY IN CYCLOHEXANE. Qichen Huang, Yanshi Zhu, Minxie Qian and Youqi Tang, Department of Chemistry, Peking University, Beijing 100871, P. R. China.

Two active trypsin inhibiting components, SPC1 and SPC2 with the same sequence of amino acid, were obtained during the synthesis of a 22-residue peptide of mimic mung bean inhibitor. The Ki values of SPC1 and SPC2 are 1.2×10^{-7} and 4.0×10^{-8} M respectively. In order to determine the difference between the structures of SPC1 and SPC2, X-ray diffraction studies were carried out on the complexes of SPC1 and SPC2 with bovine β-trypsin, only the binding loop (9 residues) of SPC1 resolved at 2.2Å resolution due to conformational flexibility of the other residues[1]. The amino acid sequence was re-determined and electrospray mass spectroscopy was also carried out to ensure that no deamidation occurred on SPC1 and the primary sequences of SPC1 and SPC2 are chemically identical. As has been proved proteins are more rigid in nonaqueous media [2,3], that is, some disordered regions may become more order when the protein crystal is transferred into organic solvents from water. So the complex of SPC1 was treated with cyclohexane for about 20 minutes and then subjected to X-ray diffraction analysis. The result showed that all the 22 residues of SPC1 were located in the electron density map perfectly. The crystal structure of SPC1 complex with bovine β-trypsin was refined to a final R value of 0.185 using data of 7.0-2.2Å resolution. So the topological structures of SPC1 and SPC2 have been determined which are responsible for the different inhibitory activity, suggesting that crystal treatment with cyclohexane may be used as a general method to determine disordered regions of proteins in the future.

P13.04.011 CRYSTAL STRUCTURE OF THE COMPLEX OF BOVINE β-TRYPSIN AND MCTI-A, A TRYPSIN INHIBITOR OF SQUASH FAMILY. Yanshi Zhu, Qichen Huang, Minxie Qian and Youqi Tang, Department of Chemistry, Peking University, Beijing 100871, P. R. China.

In our previous study of the crystal structure of the complex formed between porcine β-trypsin and MCTI-A, a trypsin inhibitor from Bitter Gourd seeds (*Momordica charantia*, Linn. *Cucurbitaceae*), five residues, including 1I, 2I at the N terminus, 11I, 19I at/near the site of contact with symmetry-related molecules, and 24I within a tight type turn, could not be identified clearly because of weak and irregular side chain electron density map[1]. MCTI-A complex with bovine β-trypsin was crystallized and its crystal structure was refined to a final R value of 0.176 using data of 7.0-1.8Å resolution. The primary sequence of the inhibitor was determined by recognizing the electron density map. These five residues mentioned above can be determined unambiguously in the electron density map. So its sequence is completely resolved as

RICPRIWMECKRDSDCMAECICVMGHCG.

The ionised electrospray mass spectroscopy was also carried out, showing that the molecular weight of MCTI-A is 3240.8±0.8, which is consistent with the sequence of MCTI-A. Compared with other squash family inhibitors, 13 amino acids of the total 28 residues of MCTI-A are conserved[2]. MCTI-A roughly exhibits the shape of a flat-iron with the base plate made up of the polypeptide chain from Met8I on, and the grip formed by the protruding reactive site loop containing the scissile peptide bond Arg5I C-Ile6I N[3]. The inhibitor has no regular secondary structures, except a type II tight turn at Met17I-Cys20I and t type I' turn at Met23I-His26I.

P13.04.012 LIGAND RECOGNITION BY SERUM AMYLOID P COMPONENT A.P. Purvis, D. Thompson, A.R. Coker and S.P. Wood [1], V. Pye [2], M.B. Pepys [3], [1]School of Biological Sciences, University of Southampton, Southampton SO16 7PX, UK, [2]Birkbeck College, Malet Street, London WC1E 7HX, UK, [3]Immunology Medicine Unit, ICSM, Hammersmith Hospital, Du Cane Road, London W12 0NN, U.K.

Serum amyloid P component is a normal plasma glycoprotein composed of 5 identical subunits, each of 23.5 kDa, known to bind amyloid deposits, DNA, a range of different proteins and various low molecular weight ligands in a calcium dependent interaction. The structure of this pentameric protein has been reported previously (1) and shows a double calcium site on each subunit as the site of ligand binding. Each subunit is made up of a flattened ß-jellyroll fold, extremely similar to that of the legume lectins. We will report a range of structures for different ligand/protein complexes that aim to map the properties of the binding site and illustrate the key residues involved in ligand recognition.

P13.04.014 STRUCTURE DETERMINATION OF HALOALKANE DEHALOGENASE LINB FROM *SPHINGOMONAS PAUCIMOBILIS* UT26. I. Smatanová and J. Marek, Laboratory of Biomolecular Structure and Dynamics, Faculty of Science, Masaryk University, Kotlářská 2, CZ 611 37 Brno, Czech Republic, Y. Nagata and M. Takagi, Department of Biotechnology, The University of Tokyo, Yayoi, Bunkyo-ku, Tokio 113, Japan, and L. Anders Svensson, Department of Molecular Bophysics, Center for Chemistry and Chemical Engineering, Lund University, S-221 00 Lund, Sweden.

Haloalkane dehalogenase LinB from *Sphingomonas paucimobilis* UT26 is an enzyme releasing chlorine or bromine from *n*-halogenated alkanes with a broad range of substrate specificity catalyses.

The enzyme was crystallized by using the hanging-drop vapor-diffusion method. The best crystals were obtaining by micro-seeding with a precipitant containing 18-20 % (w/v) PEG6000, 0.2M $CaAc_2$ and 0.1M TRIS-HCl (pH 8.9). The crystals diffract to at least 1.60 using synchrotron X-ray at cryogenic (100 K) conditions. They belong to the orthorhombic space group $P2_12_12$ with unit-cell parameters a=50.49, b=71.97, c=73.03 Å, the asymmetric unit contains one molecule of the enzyme.

Initial trials to solve the phase problem by isomorphous replacement had no success. That is why we were used isomorphous replacement method. We found two useful heavy atom derivatives: potassium tetra chloroplatinate(II), $K_2[PtCl_4]$, and potassium dicyanoaurate, $K[Au(CN)_2]$. We collected both derivative data to 2.5 Å, interpreted difference Patterson map and built MIRAS electron density map.

The poster will present our recent progress towards a crystallographic structure determination of this protein.

JM thanks Svenska Institutet for his scholarship. This work was supported in part by a grant-in-aid from the Ministry of Education, Science, and Culture of Japan (to YN and MT) and by grant VS96095 from Department of Education of the Czech Republic (to IS and JM).

P13.04.016 CRYSTALLOGRAPHIC STUDIES OF HUMAN C-REACTIVE PROTEIN/LIGAND COMPLEXES D.Thompson and S.P. Wood, Department of Biochemistry, School of Biological Sciences, University of Southampton, Southampton SO16 7PX, UK and M.B. Pepys, Immunological Medicine Unit, ICSM, Hammersmith Hospital, Du Cane Road, London W12 0NN, UK.

Human C-reactive protein (CRP) is a normal plasma protein, the circulating concentration of which rises dramatically in a cytokine-mediated response to most forms of tissue injury, infection and inflammation, and serum CRP values are widely measured in clinical practice as an objective index of disease activity. Complexed or aggregated CRP is also known to bind to the complement protein C1q and activate the complement cascade.

Several CRP-ligand complex structures have been solved with the aim of understanding the nature of interaction between this protein and its physiological ligands and also to determine the possible role played by CRP after tissue injury. Here we propose how multipoint attachment of one planar face of the CRP molecule to a cell membrane would leave possible recognition sites for C1q exposed.

P13.04.017 CRYSTAL STRUCTURE OF AN IκBα/NF-κB COMPLEX. De-Bin Huang, Tom Huxford, Shiva Malek, and Gourisankar Ghosh, Department of Chemistry and Biochemistry, University of California, San Diego, 9500 Gilman Drive, La Jolla, CA 92093-0359, USA

The crystal structure of the IκBα/NF-κB complex has been solved by a combination of multiple isomorphous replacement and molecular replacement phases and refined to an R value 0.22 and R-free 0.27 at 2.3 Å resolution.

Nuclear factor kappa B(NF-κB) is a dimeric transcription factor that regulates the expression of many cellular genes in response to a variety of signals. The classical NF-κB dimer is comprised of two subunits, p50 and p65. In resting cells, NF-κB is sequestered in the cytoplasm as complexes with inhibitor IκB proteins. Various NF-κB activating signals such as cytokines, growth factors, bacterial products, viruses, and uv light trigger a reaction cascade that ultimately phosphorylates IκB of NF-κB/IκB complexes. Phospho-IκB proteins are then ubiquitinated and degraded by the proteosome. Free NF-κB enters the nucleus to modulate transcription. Among other genes, NF-κB also induce the expression of IκBα, one of the IκB proteins. Newly synthesized IκBα, in the absence of any cytoplasmic NF-κB migrates to the nucleus and blocks transcriptional activity of NF-κB by dissociating NF-κB/DNA complexes.

The structure explains how IκBα inhibits NF-κB's function both in the cytoplasm and in the nucleus. The presence of IκBα allows large en bloc movement of the NF-κB p65 subunit amino-terminal domain. This conformational change induces allosteric inhibition of NF-κB DNA-binding. Amino acid residues immediately preceding the nuclear localization signals of both NF-κB p50 and p65 subunits are tethered to the IκBα amino-terminal ankyrin repeats impeding NF-κB from nuclear import machinery recognition.

P13.04.018 A NEW MECHANISM OF ANTIBIOTIC RESISTANCE: CRYSTAL STRUCTURE OF CHLORAMPHENICOL PHOSPHOTRANSFERASE. Tina Izard & Jacqueline Ellis Department of Biochemistry, University of Leicester, LE1 7RH, UK.

Chloramphenicol (Cm) is a broad-spectrum antibiotic produced by Streptomyces venezuelae that binds to the peptidyltransferase centre of 50S prokaryotic ribosomes thereby inhibiting protein biosynthesis. The internal mycelial resistance/tolerance mechanism of the producing organism was recently discovered to be due to a novel Cm-inactivating enzyme, chloramphenicol phosphotransferase (CPT). CPT inactivates Cm by modification of the primary hydroxyl, in this case by phosphoryl transfer between ATP and Cm. The product, 3-phospho-Cm, has little or no demonstrable antibiotic activity.

CPT from Streptomyces venezuelae has been overexpressed, purified and crystallised. The CPT-Cm crystals belong to the cubic space group I4(1)32 with unit cell dimensions a = 200 Å. Here we describe the three-dimensional structure and some insights into its mechanism of reaction.

P13.04.019 THE STRUCTURE OF THE MOLYBDATE-DEPENDENT TRANSCRIPTIONAL REGULATOR (ModE) FROM *ESCHERICHIA COLI*. David R. Hall, David G. Gourley, Lisa A. Anderson, David H. Boxer, William N. Hunter, Department of Biochemistry, University of Dundee, Dundee, DD1 5EH, United Kingdom, Gordon A. Leonard, Joint Structural Biology Group, ESRF, BP 220, F38043 Grenoble CEDEX, France, and Elizabeth M. H. Duke, CCLRC-DL, Daresbury Laboratory, Warrington, Cheshire, WA4 4AD, United Kingdom.

The molybdate-dependent transcriptional regulator (ModE) from *Escherichia coli* functions both as a sensor of intracellular molybdate concentration and a regulator for transcription of several operons involved in the uptake and utilisation of the essential element, molybdenum. The high-

resolution crystal structure of ModE was determined using multi-wavelength anomalous dispersion methods targeting a selenomethionine derivatised protein. The selenomethionyl protein and native ModE have been refined to 1.75 and 2.1Å respectively. The models describe the architecture and structural detail of a complete transcriptional regulator. ModE is functional as a homodimer and the subunits comprise distinct N-terminal and C-terminal domains. The N-terminal domain carries a winged helix-turn-helix motif for binding to DNA and is primarily responsible for dimerisation of ModE. The C-terminal domain contains the molybdate-binding site and residues implicated in binding the oxyanion are identified. This domain can be divided into sub-domains *a* and *b* which have similar folds although the organisation of secondary structure elements varies. The sub-domain fold is related to the oligomer binding-fold and is similar to that observed for the subunits of several toxins which are involved in extensive protein-protein interactions. This suggests a role for the C-terminal domain of ModE in the formation of ModE-protein-DNA complexes necessary for the regulation of transcription. Modelling of ModE interacting with DNA suggests that a large scale distortion of DNA may not be required for complex formation.

P13.04.023 MAD STRUCTURE OF THE REGULATORY SUBUNIT OF HUMAN PROTEIN KINASE CK2. L. Chantalat[1], D. Leroy[2], O. Filhol[2], A. Nuedo[2], M. J. Benitez[2], C. Cochet[2], O. Dideberg[1]. [1]LCM, Institut de Biologie Structurale Jean-Pierre Ebel, CNRS/CEA. [2] LBRCE, Unité INSERM 244, Département de Biologie Moléculaire et Structurale CEA, Grenoble, FRANCE.

Protein kinase CK2 is a heterotetramer Ser/Thr protein kinase made by the association of two α catalytic subunits (CK2α) and two β regulatory subunits (CK2β). Although its exact physiological role is not clear, CK2 is essential for the viability of *Saccharomyces. cerevisiae*. Several studies support its implication in cell division and transformation. The β subunit is important for the regulation of the enzyme and the specificity of the interaction of CK2 with substrates and inhibitors.

The crystal structure of CK2β has been solved to 1.74 Å resolution, using multi-wavelength anomalous dispersion (MAD) phasing methods. The data were collected at the ESRF, beamline BM14, on a perfectly aligned crystal. The selenium positions found with SOLVE were used to calculate experimental phases to 2Å resolution with an overall figure of merit of 0.65, yielding a map of excellent quality. An initial model was built with the program wARP. The final structure has been refined to an R_{work} = 19.3% (R_{free}= 21.8%) to 1.74 Å resolution. The model contains two CK2β subunits and 321 water molecules. The structure shows a crescent-shaped dimer with a two-fold symmetry. Two striking structural features are unique to this new structure. Firstly, a zinc finger motifs mediate the interaction between the two monomers. Secondly, the two ends of the crescent bear a highly acidic region. In this region a deep groove can easily accommodate a spermine molecule that is an activator of CK2. The CK2β structure helps in understanding the formation of the heterotetramer

P13.04.027 CRYSTAL STRUCTURE OF HUMAN ERYTHROPOIETIN COMPLEXED TO ITS RECEPTOR AT 1.9Å. Rashid Syed, Cuiwei Li, Janet Cheetham, Kenneth Aoki, Timothy Osslund, Arthur Chirino, Jiandong Zhang, Steven Elliott, Karen Sitney, John Wendoloski, Joan Egrie [1], Scott Reid, Beishan Liu, Hangjun Zhan, Bradley Katz, David Matthews [2]. Janet Finer-Moore, Robert Stroud [3]. [1] Amgen Inc., Thousand Oaks, CA 91320, [2] Axys Pharmaceuticals Inc., S. San Francisco, CA 94080, [3] University of California at San Francisco, San Francisco, CA 94143.

Human erythropoietin (EPO) is a hematopoietic cytokine required for the differentiation and proliferation of precursor cells into red blood cells. It activates by binding and orienting two cell surface receptors (EPOR) that trigger an intracellular phosphorylation cascade. The crystal structure of EPO complexed to the extracellular ligand binding domains of the EPO receptor (EPObp), determined at 1.9 Å and from two crystal forms, reveals a tri-molecular complex of one EPO and two EPObp molecules. EPO belongs to the four helical bundle cytokine family with an up-up-down-down topology. The receptor molecules are dimerized through extensive interactions at two distinct sites on EPO. The structure shows that EPO imposes a unique 120° angular relationship and orientation that may be responsible for optimal signaling through intracellular kinase pathways.

P13.04.028 ANTIBODY VERSUS ENZYME CATALYSIS: STRUCTURAL STUDIES OF ALDOLASES. A. Heine, E.A. Stura, J.G. Luz, C.F. Barbas III, C.H. Wong, R.A. Lerner and I.A. Wilson; The Scripps Research Institute, 10550 N. Torrey Pines Rd., La Jolla, CA 92037

The diversity of the immune system can be exploited to generate catalytic antibodies, which catalyze a wide variety of reactions similar to enzymes. A comparison of antibody mechanisms with those of the corresponding enzymes can illuminate the reasons for the differential rate enhancements and specificity. The natural class I aldolase enzyme has a lysine residue in the active site that forms a Schiff base during catalysis. A similar mechanism is proposed for the catalytic antibody 33F12 and indeed, was expected due to the mode of selection of the antibody by a process of reactive immunization. The structure of antibody Fab 33F12 at 2.15 Å resolution shows a lysine is buried at the bottom of the active site in a hydrophobic environment that can severely perturb its pKa. The X-ray structure determination of a corresponding enzyme, DERA, is in progress. The Se-Met substituted enzyme was used for a MAD experiment, collecting four data sets at different wavelength to 1.8 Å resolution. Crystals of the native enzyme diffract to better than 1.05 Å resolution and a complete data set to 1.07 Å has been obtained. After the molecule has been traced, the high resolution data refinement should reveal detailed insight into the mechanism of enzyme catalysis and will allow for comparison with the antibody.

P13.04.029 CRYSTAL STRUCTURE OF RAT HBP23, A NOVEL ANTIOXIDANT PROTEIN. S. Hirotsu, K. Okada, Y. Fuji, M. Kato, Y. Abe[1], N.Nagahara[1], H. Hori[1], T. Nishino[1], Y. Maru[2], and T. Hakoshima, Dept. of Molecular Biology, Nara Inst of Sci. and Tech, 8916-5 Takayama, Ikoma, Nara 630-0101, JP. and [1]Dept. Biochem. and Mol. Biol., Nippon Medical School, 1-1-5 Sendagi, Bunkyoku, Tokyo 113-8602, JP. and [2]Inst.for Medical Science, Univ. of Tokyo, 4-6-1 Shiroganedai, Minatoku, Tokyo 108-8639, JP.

HBP23 (heme binding protein 23kDa) was originally identified from rat liver cytosol with a high binding affinity with heme. Sequence analysis revealed that it belongs to a novel family of antioxidant proteins, referred to as peroxiredoxin (Prx), which has a peroxidase activity[1] . Most of Prx proteins, including HBP23, contain two conserved cysteine residues that relate to peroxidase activity and rely on thioredoxin as a source of reducing equivalents for the reduction of hydrogen peroxide. Recently, a human homologue of HBP23, Pag, has been reported to bind to SH3 domain of a non-receptor-type tyrosine kinase c-Abl and to inhibit its tyrosine kinase activity in vivo[2]. In order to understand the molecular mechanism of HBP23, we analyzed the crystal structure of HBP23 at 2.6Å resolution

For structural determination, the conventional multiple isomorphous replacement was used for phase problem. After phase improvement with solvent flipping, we obtained an

interpretative MIR density map. Several cycles of the structure refinements resulted in the current structure with an *R*-value of 0.216 (R_{free} = 0.268). This model showed that the oxidized form of rat HBP23 exists as a dimer composed of identical subunits. Each subunit contains the typical structure motif of the thioredoxin fold that contains a cental β-sheet and flanking α-helices.The active residue Cys52 of one subunit of a dimer forms a disulfide bond with Cys173 of the other subunit. Based on this structure together with biochemical results, we will discuss the mechanisms how the protein control the peroxidase activity with two conserved Cys residues and will try to identify the binding sites to heme and c-Abl.

P13.04.030 CRYSTAL STRUCTURE OF PROTEIN HISTIDINE PHOSPHATASE SIXA. K. Hamada, M. Kato, K. Ihara, T. Shimizu, T. Mizuno[1], and T. Hakoshima, Department of Molecular Biology, Nara Institute of Science and Technology (NAIST), 8916-5 Takayama, Ikoma, Nara 630-0101, JP. and [1]School of Agricultural Science, Nagoya University, Chikusa-ku, Nagoya 464-8601, JP.

SixA has been isolated from *Escherichia coli* as the first protein to exert a phospho-histidine phosphatase activity. Recent biochemical studies have shown that SixA is involved in the signal transduction of the His-Asp phosphorelay through the dephosphorylation of the HPt (histidine-containing phosphotransfer) domain of the anaerobic sensor kinase ArcB [1]. In order to understand the mechanism of action of novel protein phosphatase SixA, we have determined the crystal structure of SixA.

X-ray crystallographic analysis revealed that crystals of SixA belonged to space group $P2_12_12_1$ with unit-cell dimensions *a*=39.2, *b*=48.62, *c*=83.18Å, having one molecule in the crystallographic asymmetric unit [2]. We have determined the 2.06Å crystal structure of SixA by the multiple isomorphous replacement method (MIR) and refined the model to a crystallographic R-factor of 16.6 % and free R-factor of 22.9 %.

The structure of this protein is composed of a single α/β domain containing a central six-stranded mixed β-sheet, surrounded by five α -helices and two 310 helices on both sides. The active site contains basic residues, Arg7, Arg55 and His108, as well as the catalytic residue, His8. These positively charged residues interact with tungstate ion as a phosphate analog, suggesting that they are required for phosphate binding in the catalytic reaction.

SixA is structurally similar to the α/β domain of Phosphoglycerate Mutase, Fructose-2,6-bisphosphatase and Acid Phosphatase which catalyze the dephosphorylation of phospho-chemicals. These proteins have conserved catalytic residues, although SixA has low sequence similarity to these proteins. We have found that there is structural similarity between SixA and the low molecular weight tyrosine phosphatase from eukaryotic cells.

P13.04.031 CRYSTAL STRUCTURE OF HUMAN ZN-α_2-GLYCOPROTEIN: A FAT-DEPLETING FACTOR RELATED TO MHC MOLECULES. Arthur J. Chirino[†], Luis M. Sánchez, and Pamela J. Bjorkman[†] ,Division of Biology 156-29 and [†]Howard Hughes Medical Institute, California Institute of Technology, Pasadena, CA 91125, U.S.A.

Zn-α_2-glycoprotein (ZAG) stimulates lipid degradation in adipocytes and causes the extensive fat losses associated with some advanced cancers [1]. ZAG is normally present in serum and other tissue but is overexpressed by carcinomas that induce fat loss and not by tumors that do not. This implies that ZAG normally functions in the degradation of lipids, which increases to a pathological extent in cancer-induced weight loss, or cachexia. ZAG is a soluble protein that shares 30-40% amino acid sequence identity with the extracellular portions of class I major histocompatibility complex (MHC) heavy chains. The 2.8 Å crystal structure of ZAG resembles a class I MHC heavy chain, but ZAG does not bind the class I light chain β_2-microglobulin (ß2m). Nonetheless, ZAG's thermal stability is comparable to MHC I and other ß2m-binding molecules. The overall shape of ZAG is similar to an inverted letter L, in which the long axis of the α_3 domain is roughly perpendicular to the flat side of the α_1-α_2 platform, whereas the comparable angle is acute in ß2m-binding proteins. ZAG's overall quaternary structure in the absence of ß2m is stabilized by both the presence of additional interdomain hydrogen bonds and increased buried surface area at the α_1-α_2 and α_3 interface relative to MHC I. Although ZAG does not associate with peptides, the helices in both the α_1 and α_2 domains are almost identically positioned to their counterparts in peptide binding class I MHC molecules. The ZAG counterpart of the MHC peptide binding groove contains electron density corresponding to a hydrophobic, non-peptidic compound that may be implicated in lipid catabolism under normal or pathological conditions. ZAG and MHC-related proteins such as the neonatal Fc receptor and HFE illustrate the versatility of the MHC fold and raise intriguing questions about the ancestral function and evolutionary relationships of MHC and MHC-related proteins.

P13.04.032 CRYSTAL STRUCTURES OF DNA MISMATCH REPAIR PROTEINS. W. Yang and C. Ban, Lab. Mol. Biol., NIDDK, NIH, Bethesda, MD 20892

The MutL DNA mismatch repair protein has recently been shown to be an ATPase and belong to an emerging ATPase superfamily that includes DNA topoisomerase II and Hsp90. We report here the crystal structures of a 40KDa ATPase fragment of *E. coli* MutL (LN40) complexed with a substrate analog, ADPnP, and with product ADP. LN40 undergoes extensive conformational changes and dimerizes upon binding to the ATP analog. More than sixty residues that are disordered in the apoprotein structure become ordered and contribute to both nucleotide binding and dimerization. The rate limiting step in ATP hydrolysis is dimerization of the LN40 fragment. Hydrolysis of ATP, signified by subsequent release of the γ-phosphate, unleashes two key loops and leads to dissociation of the LN40 dimer. The nucleotide-induced structural transformation thoroughly alters the MutL contact surface and allows it to coordinate DNA mismatch repair.

P13.04.033 THE STRUCTURE OF PTERIDINE REDUCTASE 1 FROM *LEISHMANIA*. David G. Gourley, William N. Hunter, Department of Biochemistry, University of Dundee, Dundee, DD1 5EH, United Kingdom, Gordon A. Leonard, Joint Structural Biology Group, ESRF, BP 220, F38043 Grenoble CEDEX, France, James Luba, Larry W. Hardy, Dept. of Pharmacology & Molecular Toxicology,University of Massachussetts Medical School, 373 Plantation St., Worcester MA 01605 USA; Stephen M. Beverley, Dept. of Molecular Microbiology, Washington University School of Medcine,760 McDonnell Science Building, 660 S. Euclid Avenue, St. Louis, MO 63110-1093 USA.

The enzyme Pteridine reductase 1 (PTR1) from the protozoan parasite *Leishmania* is a validated target for therapeutic intervention. PTR1 is responsible for the salvage of pteridines and folates and has the ability to catalyse the same overall reaction as dihydrofolate reductase and so can confer resistance to the antifolate drug methotrexate. Crystals of recombinant PTR1 have been grown that diffract to a resolution of 2.1 Å. The space group is $P2_12_12_1$ with unit cell dimensions of a = 96.22, b = 103.86, c = 134.74 Å. Structure determination is on going and will be presented at this meeting.

05. CRYSTALLOGRAPHY OF BIOLOGICAL SMALL MOLECULES

P07.05.001 ATTEMPTS TO DESIGN PEPTIDE HELICES HAVING PREFERED SCREW SENSE USING DEHYDRO AMINO ACIDS. U.A Ramagopal and S. Ramakumar, Dept. of Physics, Indian Institute of Science, Bangalore-560012, India. R.M Joshi, and V.S Chauhan, ICGEB, Aruna Asaf Ali Marg, New Delhi-110067, India.

Peptides containing α,β-dehydroamino acid residues are found to exhibit specific conformational preference and altered biological activity. They are found in many naturally occurring peptides and proteins of microbial and fungal origin. Among the dehydro amino acids, dehydro phenylalanine(ΔPhe) is one of the well studied and has become the most promising conformation restricting residue. In order to explore the preference for particular screw sense in the $(\Delta Phe)_n$ systems, we have carried out a crystallographic analysis of two peptides namely I and II. The peptide(I) has left handed 3_{10}-helical conformation, where as the peptide(II) crystallises with two conformers per asymmetric unit. One of the conformers is a slightly distorted right handed 3_{10}-helix(A) and the other is a left handed 3_{10}-helix(B). To our knowledge this is the first observation of dehydropeptide without preferred screw sense and having chiral coded amino acid both at N-terminus and at the centre of the molecule. The crystal packing in II is mostly through C−H···O hydrogen bonds between the helices of opposite screw sense (A and B) and solvent mediated C−H···O and N−H···O hydrogen bonds. The crystal structures of the two peptides will be discussed in comparison with other ΔPhe containing peptides as well as α,α-disubstituted amino acids, highlighting the utility of ΔPhe as a complementary 'designer residue'.

	Peptide Sequence	Conformation
I	Boc-LAla-$(\Delta Phe)_4$-NHMe	TL
II	Boc-LAla-$(\Delta Phe)_4$-LAla-$(\Delta Phe)_3$-Gly-OMe	TL/R

T: 3_{10}-helix, L: Left-handed, R: Right-handed.

P07.05.002 ANTIAMOEBIN, AN INTERMEDIATE-SIZED MEMBRANE-ACTIVE POLYPEPTIDE. B.A. Wallace, C.F. Snook, Department of Crystallography, Birkbeck College, University of London, London WC1H 0HA U.K.

The structure of antiamoebin (AAM), a 16 amino acid peptaibol that can form both ion channels and carriers in phospholipid membranes, was solved by molecular replacement techniques to 1.4 Å resolution in crystals grown from methanol. Despite the fact that AAM is monomeric in the crystals, and its membrane-active form must be multimeric (the channel form is apparently a hexamer), circular dichroism spectroscopic studies confirm that its secondary structure in the crystal is the same as in phospholipid vesicles. Coincident with our solving the structure in methanol [1], Karle et al [2] also solved its structure in crystals grown from octanol. Even though the solvents used were considerably different in their chemical properties, and the packing of the molecules in the two crystal forms was different, the two structures are virtually identical. They are helical molecules with a deep bend in the middle caused by the presence of three imino acids. Their polypeptide main chain atoms differ by only ~0.25 Å RMSD, and their bend angles by less than 3 degrees. The angle of the bend in AAM is much larger than it is in zervamcin, a highly homologous (44 % identical) molecule, and is likely an important reason for the difference in membrane activity profiles between these two molecules. AAM is unique, with respect to membrane-active peptides examined to date, in that it can act as either an ion carrier and an ion channel, depending on the type of lipids used to form the membrane [3]. Models for the two functional forms are proposed based on the crystal structure and functional studies.

P07.05.003 MOLECULAR PACKING FEATURES OF C-TERMINAL AMIDATED AMINO ACIDS AND DIPEPTIDES. Y. In, M. Fujii, S. Tani, K. Tomoo, T. Ishida, Department of Physical Chemistry, Osaka University of Pharmaceutical Sciences, 4-20-1 Nasahara, Takatsuki, Osaka 569-1094, Japan

Most of the biologically active peptides such as endomorphin-1, fulicin, dermorphin and calcitonin are amidated at the C-terminal, and the activities are disappeared when they are deamidated. We believe such drastic change could result from the change in the interaction mode of the peptide with the receptor, rather than the molecular conformation change. Especially, the hydrogen-bonding pattern at the binding pocket of receptor could be expected to be largely different between the C-terminal free and the amidated peptides. The three-dimensional information on the C-terminal amidated bioactive peptide–receptor complex is not available at present. So, we analysed the crystal structures of C-terminal amidated amino acids and dipeptides, and compared the respective intermolecular interactions with those of the corresponding free amino acid and dipeptides, in order to examine the role of C-terminal amidation for the intermolecular packing, because these information would be useful to consider the binding mode which is necessary for its bioactivity of the peptide in the active site of receptor.

A series of C-terminal amidated amino acids and peptides were dissolved in various solvents or their mixtures, and single crystals of C- terminal amidated Tyr, AcTyr, Cys(trt), Trp, Glu, Val, Asp, Ile, Thr, Tyr-Lys, Z-Gly-Phe and Asp-Phe were obtained from water, alcohol, water/alcohol mixture, or alcohol/ethyl acetate mixture by the slow evaporation at room temperature. The respective structure determination and refinement were carried out in the usual way. When the respective molecular conformations were compared with those of the corresponding free amino acids and dipeptides, the common conformational change by the amidation was not observed. Alternatively, the intermolecular interactions, including hydrogen bonding pattern, was very similar to one another, and was considerably different from those observed for the free amino acids and peptides The detailed analyses are now in progress.

P07.05.004 PEPTIDE DESIGN: A DISTORTED 3_{10} HELIX IN A DEHYDRO HEXAPEPTIDE Boc-Val-ΔPhe-Leu-Ala-ΔPhe-Ala-OMe. S. Ramakumar[1], Anil Kumar P.[1], V. S. Chauhan[2], [1]Department of Physics, Indian Institute of Science, Bangalore – 560 012, India. [2]International Centre for Genetic Engineering and Biotechnology, Aruna Asaf Ali Marg, New Delhi - 110 067, India.

α,β-Dehydro amino acid residues are found in several naturally occurring bioactive peptides as well as in some proteins. Their presence in peptide chain produces remarkable conformational consequences. As a part of our program on *de novo* design of protein secondary structure mimetics, we have determined the X-ray crystal structure to atomic resolution of a dehydro hexapeptide Boc-LVal[1]-ΔPhe[2]-LLeu[3]-LAla[4]-ΔPhe[5]-LAla[6]-OMe. Crystals grown in aqueous methanol solution by the slow

evaporation method belong to monoclinic space group $P2_1$, with cell dimensions *a*=10.90, *b*=10.07, *c*=20.00Å, β=94.4°, Z=2. The crystal structure was determined using direct methods and refined using least-squares technique to R-factor better than 5.3% for 3025 reflections having $|F_o| \geq 4\sigma |F_o|$. The peptide is stabilised by three consecutive and overlapping type III β-turns. The overall structure of the molecule is a right-handed, distorted 3_{10} helix with an average (ϕ, ψ) value of (-67.7°, -22.7°) and ranging from (-81.1°, -9.6°) for ΔPhe^5 to (-55.1°, -36.3°) for Leu^3. Comparison of the structure with those of other dehydro oligopeptides suggests that the helical conformation of the hexapeptide might have arisen due to the presence of a bulky Leu^3 residue in the two residue spacer segment between ΔPhe^2 and ΔPhe^5. The crystal packing is in the form of helical rods aligned along the crystallographic *a*-axis. The helical rods are connected in head to tail fashion with N-H···O hydrogen bonds with additional support from C-H···O hydrogen bonds. The overall crystal packing is mainly through hydrophobic interactions with adjacent helices being anti parallel to each other.

P07.05.005 SOLID STATE CONFORMATION OF SERINE^3-DPDPE. Judith. L. Flippen-Anderson,[1] Jeffrey R. Deschamps, [1] Clifford George, [1] Victor J. Hruby,[2] Mark Shenderovich,[2] Andrzej Lipkowski,[3] and Aleksandra Misicka[4] from [1]Laboratory for the Structure of Matter, Naval Research Laboratory, Washington, DC 20375 USA, [2]Dept of Chemistry, University of Arizona, Tucson, Arizona 85721 USA, [3]Medical Research Centre, Polish Academy of Sciences, Warsaw, Poland and [4]Dept of Chemistry, Warsaw University, Warsaw, Poland

Understanding the structural basis of receptor selectivity for opioid peptide – receptor interactions requires extensive study of the conformational (φ,ψ) and topographical (χ^1, χ^2) properties of the peptide ligand. The enkephalins themselves are not very useful in these studies because of their low selectivity and their high degree of conformational freedom. Early work on these ligands did identify the 2 aromatic rings, an amino group, and a lipophilic surface as key pharmacophoric elements. Systematic rational approaches to designing more potent and selective ligands have endeavored to preserve these key structural elements. One of the first successes of this approach was the development of the highly potent and δ opioid receptor-selective enkephalin analogue DPDPE (Tyr-cyclo(D-Pen-Gly-Phe-D-Pen)-OH). DPDPE is now the δ opioid receptor selectivity standard against which new derivatives are measured for specificity and potency. We have already reported on the solid state structure of DPDPE itself as well as a number of modified DPDPE compounds. This paper will describe the X-ray structure of Ser^3-DPDPE which has a lower affinity for the δ receptor site, but is possibly more selective [A. Misicka, et al, Peptides Chemistry and Biology, J. A. Smith and J. E. Rivier (Eds) ESCOM, Leiden, The Netherlands, 1992, p140-141]. Small crystals (0.05 x 0.1 x 0.25 mm) were grown by vapor diffusion and data were collected at –75°C on a 1K Bruker Smart CCD system using a 5 kW Cu rotating anode and Göbel mirror system. It crystallizes in the monoclinic space group $P2_1$ with 2 independent peptide molecules and several water molecules per asymmetric unit. The structure was solved and refined on F^2 values using SHELXTL-PLUS. Supported in part by ONR and NIDA.

P07.05.006 STRUCTURAL STUDIES ON COLLAGEN-MODEL PEPTIDES WITH (Pro-Pro-Gly) AND (Pro-Hyp-Gly) SEQUENCE REPEAT. V. Nagarajan, S. Kamitori and K. Okuyama, Faculty of Technology, Tokyo Univeristy of Agriculture and Technology, 2-24-16, Naka-cho, Koganei-shi, Tokyo 184-8588, Japan.

Even though the elucidation of the structure of collagen have been attempted for a very long time, the exact structure of collagen has not been known, till date. Several models for collagen have been proposed of which two have been generally accepted, one is the 10/3-helical model [1] while the other is the 7/2-helical model [2]. Due to difficulties in analyzing the detailed structure of collagen, those peptides which mimic the triple helical nature of collagen have been the targets of study. Two such collagen model peptides namely, $(Pro\text{-}Pro\text{-}Gly)_{10}$ and $(Pro\text{-}Hyp\text{-}Gly)_{10}$ have been analyzed. The average structures of these peptides, have revealed that, these triple helical peptides are essentially the same as the 7/2-helical model. Similarity in their molecular structure clearly shows that presence of hydroxyproline at the Y-position does not have any structural influence in the imino acid rich regions of collagen. The packing considerations of these peptides are different, implying that hydroxyproline does have an influence on the local environment of the triple helix. The number of water molecules identified in our study was considerably lower than that obtained by a different group [3,4] because of differences in the refinement procedure, while we took crystallographic free *R* into consideration, the other group did not. Identification of a considerably lower number of water molecules in hydroxyproline containing peptide seem to support a recent report [5] that the extra stability associated with the hydroxyproline containing peptides may not be due to the excess water bridges formed by the hydroxyl group of the hydroxyproline.

P07.05.007 IS THE RICH AND CRICK MODEL FOR COLLAGEN REALLY TRUE? –EVIDENCES FROM MODEL PEPTIDES. K.Okuyama, V.Nagarajan, C.Hongo and S.Kamitori, Tokyo University of Agriculture and Technology, Koganei, Tokyo 184-8588, Japan.

Collagen molecule has a triple-helical structure due to the strict sequence constraints with glycine as every third residue and a high content of imino acids. After about fifty years since this triple-helical structure was proposed, the prevailing model is the Rich and Crick model in which three strands form a left-handed 10/3-helix with an axial repeat of 28.6Å [1]. However, there is one more model which can explain X-ray fiber diffraction patterns of native collagen. That is the Okuyama model in which three strands form a left-handed 7/2-helix with an axial repeat of 20Å[2]. This was deduced based on the structure of (Pro-Pro-Gly)10 single crystal by means of the linked-atom technique used for fiber diffraction analyses. Recently, we succeeded in obtaining single crystals of collagen model peptides, (Pro-Pro-Gly)n (n=9, 10, 11), (Pro-Hyp-Gly)10 and (Pro-Pro-Gly)4 -X-Y-Gly-(Pro-Pro-Gly) 4 with one of (X=Ala, Y=Pro), (X=Pro, Y=Ala) and (X=Y=Ala). Structure of (Pro-Pro-Gly)n (n=9, 10) and (Pro-Hyp-Gly)10 were analyzed by means of the recent technique. All the obtained structures in this study together with the results from other groups confirmed that these molecular structures were essentially the same as the Okuyama model. Furthermore, not only these three, all the X-ray diffraction data in this study showed the 7/2-helical symmetry and 20Å axial repeat (Okuyama model) from their cylindrical Patterson maps. On the other hand, the Rich and Crick model has no such supporting data other than fiber diffraction analysis of collagen.

P07.05.008 ELECTROSTATIC STABILIZATION OF BOUND OXYGEN IN MYOGLOBIN. R.R. Leininger, Y. Dou, G. N. Phillips, Jr., and J.S. Olson, Department of Biochemistry and Cell Biology, Rice University, Houston, TX.

The distal histidine, His64(E7),in myoglobin (Mb) has been shown to play an essential role in governing relative carbon monoxide and oxygen affinities, specifically by the polarity of its imidazole side chain. This residue promotes O_2 binding by preferential formation of a hydrogen bond with the Fe-O_2 complex and inhibition of CO binding by the requirement for water displacement from the distal pocket of deoxyMb. Double mutants have been constructed to test the general importance of favourable electrostatic interactions by replacing the distal histidine with an apolar leucine residue and then adding hydrogen bond donors at other positions adjacent to the bound ligand. The H64L/V68N double substitution causes an ~2-fold increase in O_2 affinity compared to wild-type Mb, whereas the H64L/V68Q replacements cause an ~100-fold decrease. Analyses of the x-ray crystal structures and IR spectra of these proteins show, in agreement with the work of Kryzwda et al. [1] on single mutants, that the amide side chain of Asn68 can form a strong hydrogen bond with bound O_2, whereas the side chain of Gln68 is too large causing the amide to point away from the active site.

P07.05.009 CRYSTALLOGRAPHIC STUDIES OF A LYTIC PEPTIDE WITH ANTI-BACTERIAL AND ANTI-TUMOR ACTIVITIES. Hidong Kim[1], Lance J. Stewart[1], Jesse M. Jaynes[2]. [1]Emerald BioStructures, Inc., 7869 NE Day Rd. W, Bainbridge Island, WA 98110, USA; [2]Demegen, Inc., 1051 Brinton Rd., Pittsburgh, PA 15221, USA.

Naturally occurring lytic peptides have innate immunological activities in various species. These peptides, such as the cecropins produced by the giant silk moth *Hyalophora cecropia* and the magainins found in the skin of the frog *Xenopus laevis*, show antimicrobial activity. Their natural functions may thus be to protect the host against bacterial infection. Although diverse in amino acid sequence, these lytic peptides of 20-40 residues exhibit a characteristically positively charged and amphipathic helical or sheet structure, indicating that overall physical properties may be more important than specific residues in their lytic functions. The mechanism of action of the naturally occurring lytic peptides is not fully understood, but lysis is thought to result from interactions of the peptide with the cell membrane itself, rather than via a specific peptide-receptor interaction.

Peptidyl membrane interactive molecules™ (MIMs) are synthetic peptides based on the properties of naturally occurring lytic peptides. These synthetic peptides show cytotoxic effects against both cancer cells and pathogenic bacteria. The LD_{50} of one 23-mer Peptidyl MIM™, D2A21, is 0.882 μM against a certain prostate cancer cell line. This compares well to the LD_{50} of the standard chemotherapeutic agent cisplatin, which ranges from 2-17 μM against the same cell line. D2A21 is also effective in killing pathogenic bacteria, with MICs of <1 μg/ml against *Pseudomonas aeruginosa*, and <10 μg/ml against methicillin-resistant *Staphylococcus aureus*. These findings indicate that Peptidyl MIMs™ may be effective as chemotherapeutic or antibiotic agents. Here, we present results of our X-ray crystallographic studies of D2A21.

P07.05.010 STRUCTURE OF SHORT CHAINS OF THE OLIGOPEPTIDE TYPE. J.Hasek, J.Duskova, Institute of Macromolecular Chemistry, Academy of Sciences of the Czech Republic, Heyrovskeho nam.2, 162 06 Praha 6

Several types of short peptide-like synthetic chains possessing a large scale of enzymatic stabilities and activity are studied for their applications as enzymatically degradable spacers for polymer drug carriers, enzymatically activated suicide inhibitors, substrate-like directed inhibitors.

The global hydrophobicity, conformational flexibility, position and orientation of hydrophobic and hydrogen-bond-forming monomers are decisive for enzymatic activity of oligomer. Therefore, the classification of substrate or inhibitor oligomers should be based on graphical representation of all these global and spatial properties.

The crystal structures and models based on empirical potentials of several peptide-like chains are discussed in detail. Special attention is devoted to Boc-Gly-L-Leu-Gly-p-nitro-phenyl, as a representative of enzymatically degradable spacer, (4S)-4-[1-(N-butoxycarbonylamino)-2-phenyl]-2,2-dibenzyl-4-butyrolactone and at last subnanomolar (K_i range 0.02-200 nMol) peptide-like inhibitors of HIV protease Boc-Phe-Ψ[(R/S)CHX CH_2 NH]-Phe-Glu/Gln/Ile-Phe-NH_2 , where X=H or OH /1/. Comparison with similar molecular structures compiled in CSD /2/ and IsoStar /3/ show some similar features of these distinct groups of compounds.

The project is supported by GACR 203/98/PO31, GAAV A4050811 and thanks to GA CR 203/99/0067 for providing the structural databases.

P07.05.011 MEMBRANE ION TRANSPORT BY ANTIBIOTICS AND TOXINS. W.L. Duax[1], B.M. Burkhart[1], D. Ghosh[1,2] N. Li[1], [1]Hauptman-Woodward Institute, Buffalo, NY 14203, [2]Roswell Park Cancer Institute, Buffalo, NY 14263, and V. Pletnev[3], [3]Shemyakin Institute, Moscow, Russia.

Recent X-ray crystal structure determinations a Cs^+, K^+, and Rb^+ complexes of gramicidin D and an NH_4^+ complex of a virally encoded killer toxin, KP6a, reveal previously undetected modes of ion coordination that are ideally suited to facile movement of ions through membrane channels. Our isomorphous crystal structures of Cs^+, K^+, and Rb^+ gramicidin D revealed a right-handed anti-parallel double stranded double helix (DSDH5) that is consistent with a large body spectroscopic data. The DSDH5 structure has an ion channel with a single partially solvated Cs^+ ion distributed over three binding sites. The channel is relatively smooth and electrostatically negative on the interior as required for cation passage, while the exterior is electrostatically neutral, a requirement for membrane insertion. The "coordination" of the Cs^+ ion is achieved by interaction with the π orbitals of the carbonyls which do not point toward the ions. The K^+ binding sites, which are similar in position to Cs^+ binding sites, are shifted off center towards the wall of the channel. Our X-ray crystal structure determination of KP6a has revealed a trimer stabilized by salt bridges that forms a solvent filled funnel with charged residues on the inside. The funnel tapers to an opening which is lined by three phenyl rings. The 4.2Å diameter opening at the center of the phenyl rings has ideal dimensions to coordinate to NH_4^+ and K^+ ion via the π clouds of the phenyl rings. Electron density on the symmetry axis within the barrel of

the funnel surrounded by the phenyl rings is compatible with an NH_4^+ ion. The observed ion coordination is analogous to the arrangement of phenyl rings around NH_4^+ and K^+ ions in crystals of ammonium and potassium tetraphenylborate. This type of coordination for K^+ has been proposed to account for ion selectivity in insect and mammalian K^+ channels on the basis of ab initio calculations.

P12.05.001 (3,3-DICHLORO-4-(P-METHOXY-PHENYL)-1-(P-CHLOROPHENYL)-2-AZETIDINONE). T. N. Durlu, K. Güven, M. Kabak, Department of Physics, Faculty of Art and Sciences, University of Kırıkkale, 71450 Yahşihan, Kırıkkale, Turkey, and V. Güner, Department of Chemistry, Faculty of Sciences, University of Hacettepe, 06532, Beytepe, Ankara, Turkey.

The crystal structure of the title compound, $C_{16}H_{11}Cl_3NO_2$, is monoclinic, $P2_1/n$, a=5.865(2), b=14.179(3), c=19.487(3) Å, ß=94.33(4)º, V= 1615.7(7) $Å^3$, Z=4, D_x=1.466 Mgr/cm^3, $\lambda_{MoK\alpha}$=0.71073 Å [1]. The Cl1-C8-Cl2 plane is nearly perpendicular to the four membered β-lactam group 89.6(2)º and the C-C bond distances on this lactam group are 1.550(8) and 1.568(7)Å, respectively. The most deviated atom from the N1-C7-C8-C9 plane is C7 atom with the 0.030(4) Å [1]. Chlorophenyl and methoxyphenyl rings are nearly perpendicular to each other (81.1(4)º). The antibacterial activity of the monocylic ß-lactam compounds could be explained by the non-planarity of the lactam ring [2 and references therein] and the ß-lactam compounds show important role in the antibacterial compounds [3, 4]. Besides, selectivity or activity can be decisively influenced by the substituents of the β-lactam ring [5, 6]. Quantum mechanical calculations were carried out to investigate the conformation analysis of the crystal structure according to the AM1 methods and compared with the previous studies.

P12.05.002 (3, 3-DICHLORO-1, 4-DIPHENYL-2-AZET-IDINONE). K. Güven, T.N.Durlu, M.Kabak, Department of Physics, Faculty of Art and Sciences, University of Kırıkkale, 71450 Yahşihan, Kırıkkale, Turkey, and V.Güner. Department of Chemistry, Faculty of Sciences, University of Hacettepe, 06532, Beytepe, Ankara, Turkey.

The crystal structure of title compound, $C_{15}H_{11}NOCl_2$, is monoclinic, C2/c, a=19.305(2), b=5.958(1), c=23.847(2) Å, β=91.9(8)°, V=2741.0(5)A^{-3}, Z=8, D_x= 1.416 Mgr/cm^3, $\lambda_{MoK\alpha}$=0.71073 Å. The Cl1-C8-Cl2 plane is nearly perpendicular to the four membered β-lactam group 89.0(2)º and the C-C bond distances on this group are 1.571(6) and 1.543(7) Å, respectively. The most deviated atom from the N1-C7-C8-C9 plane is C7 (-0.025(5) Å). Two phenyl rings are nearly perpendicular to each other 77.4(2)º. Developments in the field of β-lactams during the last decade have shown that the only essential feature for the antibacterial activity in these compounds is the presence of β-lactams ring (2-azetidinone) [1, 2, 3, 4]. Selectivity or activity can be decisively influenced by the substituents of the ring [5, 6]. It was reported that the biologically activity of the β-lactams by Chambers and Doedens, 1980 and the structural studies Ercan, Ülkü & Güner, 1996; Ülkü, Ercan & Güner, 1997. The four atoms of lactam ring are coplanar to within the experimental error in other β-lactams [10].

P12.05.003 STRUCTURE & CONFORMATION OF 2,10 -DICHLORO DIBENZO[D,G] [1,3,6,2] DIOXATHIA AND [1,3,2] DIOXA-PHOSPHOCIN-6-OXIDES. M. Krish-naiah, N. Jagadeesh Kumar, Department of Physics, Sri Venkateswara University, Tirupathi - 517 502. India.

Heterocycles with suitably substituted Phosphoryl unit exhibit significant Physiological activity. These compounds are often important interms of multiple applications as insecticides, bactericides, fungicides and also in polymer and oil industries as stabilizer and antioxidants. Some of these family were evaluated for toxicity in the insect P-americana. The structural investigations on the titled compounds have been studied to understand the conformation of heterocyclic rings & to identify the biological active phosphorus moieties. The present study is devoted on (I) 6-[bis(2-chloro-ethyl) amino] , (II) 6-tri-chloromethyl 2,10-dichloro dibenzo [d,g][1,3,6,2] dioxathiaphosphocin 6-oxides, (III) 1,2,4,8,10,11- hexachloro-6- trichloromethyl & (IV) 2,10 dichloro-6-[bis-(2-chloromethyl)amino] 12-trichloromethyl 12H-dibenzo-[d,g][1,3,2] dioxaphosphocin 6-oxides.

Crystal data: (I) $C_{16}H_{14}Cl_4NO_3PS$, Monoclinic $P2_1/c$ a=9.188(2), b=20.588(5), c=10.861(3)Å , β = 102.5 (2)°, Z=4, R=0.034 for 2932 reflections. (II.) $C_{13}H_6Cl_5O_3PS$, $P2_1/n$, a = 11.624(7), b=11.091(3), c=14.407(4)Å, β = 107.8(3)º, Z=4, R = 0.045 for 2525 reflections. (III) $C_{14}H_4Cl_9O_3$ P, $P2_1/c$ a = 9.235(4), b=23.155(3), c=9.301(3)Å, β= 98.9(3)°, Z=4, R=0.035 for 2733 reflections. (IV) $C_{18}H_{15}Cl_7O_3P$, orthorhombic $P2_12_12_1$ a = 11.566(3), b= 12.836(4) and c=15.312(4)Å, Z=4, R=0.041 for 2011 reflections. All the strucutres solved by direct methods and refined by full matrix least square methods using SHELXS-86 & SHELXL-93.

The conformation for the eight membered dioxathiophophocin ring is a boat-chair(B.C.) in I , twist boat (T.B) in II and for dioxaphosphocin ring it is a distorted boat (D.B) in III and IV. The orientation of the substitutents and their influence on the conformation and geometrical parameters are compared to the corresponding ones reported and discussed with respect to their biological activity.

P12.05.004 CRYSTAL AND MOLECULAR STRUCTURE OF CINCHONAN ALKALOID K.A. NIRMALA, P.KUMARADHA Dept. Of Physics, Bangalore University, Jnana Bharathi, Bangalore 560056, Karnataka, India

The crystal structure of the title compound ($C_{27}H_{29}ClN_2O_3.HCl$) has been studied due to their considerable interest as antimalarial drug. The crystals were grown from acetone. Crystal data: orthorhombic, $P2_12_12_1$, Z=4, a=11.745(3), b=12.353(6) c=17.253(6) A and V=2503(2) A^3. The structure has

been solved by Direct methods using SHELXS-86 and refined by least-squares method using SHELXL-93 to the final R value 0.062 for 2155 observed reflections The detailed molecular conformation of the structure and the effect of the substituents on the molecular geometry, that is, the conformation of the quinuclidine ring and chlorobenzoate group will be discussed.

P12.05.005 STRUCTURE AND CONFORMATION OF 4,4 DIETHOXY CARBONYL -3,5(4-METHYL PHENYL)-1-THIAN-1,1, DIOXIDE. S. Narasinga Rao, Department of Physics, University of Central Oklahoma, Edmond, OK, USA; M. Krishnaiah, N. Jagadeesh Kumar, Gan Srinivasa Rao, Department of Physics, Sri Venkateswara University, Tirupati 517502, India; D. Bhaskar Reddy, M. Muralidharan, Department of Chemistry, Sri Venkateswara University, Tirupati 517502, India; G. Aguirre-Hernandez, F. Ortega-Chocote, and Manuel Soriano-Garcia, Centro de Gradudos e Investigacion del Instituto Technologico de Tijuana, Mexico

Considerable interest has been shown in the crystal structural studies of heterocyclic compounds, particularly the ones containing sulfur in the ring at the 1-position, mainly because of their wide spectrum of physiological action. They find applications in pharmacology, bacterial and fungicidal studies.

The study of the present crystal has been undertaken to understand the effects of substituents on the conformation of the heterocyclic rings and its geometrical parameters.

The compound ($C_{25}H_{30}O_6S$) crystallizes in space group P-1. The cell parameters are a=8.9010(10), b=11.700(2), c=13.0260(10) Å, α=64.24°, β=88.97°, γ=78.97°, V=1195.9(3) Å^3. There are 2 molecules in the unit cell. The structure has been refined to a final R factor of 0.07.

In the structure, thian dioxide assumes a chair conformation as expected like in the cyclohexane moiety in its preferred rigid conformation. The two aryl groups at 3 and 5 adopt an equatorial position in cis-conformation. The structure is stabilized by H-bonds C-H...O and van der wall contacts.

P12.05.006 STRUCTURE AND CONFORMATION OF 4,4 DIMETHOXY CARBONYL -3,(4-CHLORYL PHENYL)-1-THIAN-1,1, DIOXIDE. M. Krishnaiah, N. Jagadeesh Kumar, Gan Srinivasa Rao, Department of Physics, Sri Venkateswara University, Tirupati 517502, India; D. Bhaskar Reddy, V. Narasinga Rao, Department of Physics, University of Central Oklahoma, Edmond, OK, USA

Considerable interest has been shown in the crystal structural studies of heterocyclic compounds, particularly the ones containing sulfur in the ring at the 1-position, mainly because of their wide spectrum of physiological action. They find applications in pharmacology, bacterial and fungicidal studies.

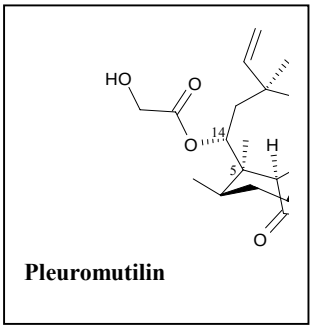
The study of the present crystal has been undertaken to understand the effects of substituents on the conformation of the heterocyclic rings and its geometrical parameters.

The compound ($C_{22}H_{23}Cl O_6S$) crystallizes in space group P-1. The cell parameters are a=9.1980(10)Å, b=10.2320(10)Å, c=12.625(2)Å, α=74.653(9)°, β=72.459(9)°, and γ=78.827(9)°. V=1084.1(2) Å^3. There are 2 molecules in the unit cell. The structure has been refined to a final R factor of 0.07.

In the structure, thian dioxide assumes a chair conformation as expected like in the cyclohexane moiety in its preferred rigid conformation. The two aryl groups at 3 and 5 adopt an equatorial position in cis-conformation. The structure is stabilized by H-bonds C-H...O and van der wall contacts.

P12.05.007 STRUCTURAL INVESTIGATIONS ON PLEUROMUTILINS: A SERIES OF ANTIBIOTICS TO COUNTER BACTERIAL RESISTANCE. Royston C. B. Copley[1], Drake S. Eggleston[1], R. Curtis Haltiwanger[2] & Eric Hunt,[1] SmithKline Beecham Pharmaceuticals, Research and Development, [1] New Frontiers Science Park (North), Third Avenue, Harlow, Essex CM19 5AW, UK and [2] P.O. Box 1539, King of Prussia, Pennsylvania 19406, USA.

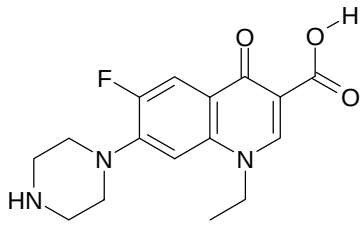
Bacterial resistance to existing antibiotics is an issue of international concern and has been the subject of much media attention. To combat this problem, the pharmaceutical industry is looking to identify drug molecules whose mode of action is distinct from those of established agents and which display activity against the resistant bacterial strains. Pleuromutilin is just such a compound and is a natural product that was first isolated from the basidiomycete *Pleurotus mutilus* in the early 1950s. Whilst semi-synthetic pleuromutilins were studied in the 1970s and 1980s by the Sandoz group, no drug was ever brought to the market for human use. Investigation of such under-exploited antibiotics represents a realistic approach to solving the problem of resistant bacterial strains.



Pleuromutilin

We describe the single crystal X-ray structure of the natural product and of a number of semi-synthetic pleuromutilins derived from this. The tricyclic core represents a rigid moiety which generally remains unperturbed as substituents are varied as will be illustrated by a series of structures where there is interchange of the side chain at position 14. The conformational effects of opening the five and six-membered rings will be described, as will the effect of introducing functionality that dictates a dramatic conformational change.

P12.05.008 CRYSTALLISATION AND CHARACTER-ISATION OF PSEUDOPOLYMORPHS OF NOR-FLOXACIN. E. A. Wright, A. J. Florence and N. Shankland, Department of Pharmaceutical Science, University of Strathclyde, Glasgow G4 0NR, UK, and A. R. Kennedy, Department of Pure and Applied Chemistry, University of Strathclyde, Glasgow G1 1XL, UK, and P. J. Cox, School of Pharmacy, Robert Gordon University, Aberdeen AB10 1FR, UK



Norfloxacin ($C_{16}H_{18}FN_3O_3$) is a fluoroquinolone antibiotic that is active against a large variety of Gram-positive and Gram-negative bacteria.

Although two polymorphic forms of norfloxacin have been reported [1], no crystal structures are currently available in the literature. We have crystallised norfloxacin from a range of organic solvents at room temperature and screened for polymorphs using FT-IR and DSC. From these samples, two crystal structures have been determined, and are reported here for the first time. The first is a dihydrate (monoclinic $P2_1/c$, a = 8.265(3), b = 21.698(4), c = 9.525(17) Å, β = 110.79(2)°); the second is a disordered hydrate (monoclinic, $P2_1/a$, a = 8.573(17), b = 22.288(2), c = 8.837(2) Å, β = 106.93(2)°), in which the water molecules and the ethyl side chain are disordered. A comparison of these crystal structures is presented.

[1] B.Sustar,N. Bukovec,and P.Bukovec, J. Thermal Anal., 40 (1993), 475-481

P12.05.009 CRYSTAL STRUCTURE OF (23S, 25R)-3β-BROMO- 6β-ACETOXY-5α-SPIROSTAN-23-OL MONO-HYDRATE. O. Au-Alvarez, Dept. of Chemistry, Fac. of Sciences, University of Oriente, Santiago de Cuba 90500, Cuba, R. C. Peterson, Dept. of Geological Sciences, Queen's University, Kingston, Ontario K7L 3N6, Canada, M.A. Iglesias Arteaga, R. Pérez Gil and F. Coll Manchado, Lab. of Natural Products, Fac. of Chemistry, University of Havana, Havana, Cuba and R. Pomés Hernández, National Center for Scientific Research, P.O.Box 6990, Havana, Cuba.

During our study of bioactive steroids derived from sapogenins we synthesized the title compound (I), $C_{29}H_{47}BrO_6$. After the synthesis it was questioned whether it crystallized in anhydrous form or hydrated. In order to solved this question we undertook the determination of its crystal structure. The results obtained in this study clearly showed that (I) crystallizes with one molecule of water. This molecule is linked to the 23-hydroxil group of the spyrostan moiety via a hydrogen bond. The compound is monoclinic, space group $P2_1$ with a=16.404(5), b=7.135(5), c=12.536(5) Å, β=103.32(3)^o and Z=2. The Br atom bonded to C3 is equatorially oriented and does not disturb the chair conformation of ring A. Rings C, D and F also have chair conformation [1]. The A/B, B/C and C/D ring junctions are trans. The angle between the l.s. plane to ring A and that to B-C-D is 5.10^o. Ring D has a 15β-envelope conformation. The molecule is practically not twisted about the length of the molecule as is evident from the value of the C19-C10...C13-C18 pseudotorsion angle [2]. The carbonyl distance (1.198 Å) of the acetate group is smaller than expected. The angle between the l.s. plane to the four non-hydrogen atoms of the acetate group and the B l.s. plane is 75.9^o.

P12.05.010 PSEUDOSYMMETRY AND DISORDER IN THE STRUCTURE OF CHOLESTEROL AT 37° C. Christer E. Nordman and Leh-Yeh Hsu, Department of Chemistry, University of Michigan, Ann Arbor, MI 48109, USA.

This structure, space group P1, Z = 16, is refined in a cell with *a* = 27.565, *b* = 38.624, *c* = 10.748, α = 93.49, β = 90.90, γ= 117.15, related to the "reduced" cell [1], by **a** = $\mathbf{a}_{red}$, **b** = $\mathbf{b}_{red}$ - $\mathbf{a}_{red}$, **c** = $\mathbf{c}_{red}$. This unit cell is related to the room temperature cell [2], similarly transformed, by an approximate doubling of the *a*-axis. The structure shows a remarkable 2-fold rotational and screw-rotational pseudosymmetry. The "pseudoasymmetric unit" is the 8-molecule cluster A1, B1, C1, D1, A2, B2, C2, D2 in the previously used notation [1], comprising half of the cell content. This cluster is related to the other half of the unit cell, E2, F2, G2, H2, E1, F1, G1, H1, by a "$2_{0.5,\ 1.5}$" screw axis nearly parallel to **c**, at *x*,*y* = 0, 0.5 and 0.5, 0.5, and having alternating translational components of Δ*z* = 0.25 and 0.75. Parallel with these are 2_1 screw axes at x, y = 0,0 and 0.5, 0, which relate, respectively, the A1, .., D2 cluster to the E2,..,H1 cluster in the cell translated by –**b** or to that in the cell translated by –**b**–**a**. Coaxial with these are 2-fold rotation axes which relate A1,..,D2 to E2,..,H1 in the cell translated by +**b**. These symmetries extend throughout the structure in the **a** and **b** directions. In the *z*-direction the pseudo-symmetry is less closely obeyed as these 2-fold axes are not exactly parallel with the **c**-axis, but make an angle of 1.4° with it. The side chains of all the cholesterol molecules suffer from high thermal motion or disorder. Despite this it is clear that many of the side chains obey the pseudosymmetry closely. In other cases the difficult-to-model disorder may show some violation.

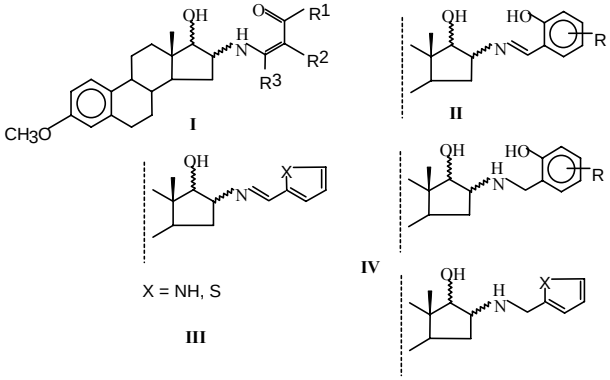
P12.05.011 STEROIDS AS CHIRAL LIGANDS: SYNTHESIS AND CRYSTAL STRUCTURES OF 1-ENAMINO-3-OXO COMPOUNDS AND AZOMETHINES FROM STEROIDAL AMINO ALCOHOLS. H. Görls, Institut für Anorganische und Analytische Chemie der Universität Jena, August-Bebel-Str. 2, 07743 Jena, Germany, M. Dubs, R. Krieg and B. Schönecker, Institut für Organische und Makromolekulare Chemie der Universität Jena, Humboldtstr. 10, 07743 Jena, Germany.

For stereochemical and biological investigations new steroids as chelating ligands have been synthesized. Condensation of the four 16-amino-17-hydroxy-3-methoxy-estra-1,3,5(10)-trienes with aliphatic 1,3-dioxo compounds (or derivatives), aromatic ortho-hydroxy aldehydes or heteroaromatic a-aldehydes gave 16-(1-enamino-3-oxo) compounds with a 17-hydroxy group (type I) or the corresponding 16-imines (type II and III), respectively. By reduction of compounds of the type II and III new N-substituted 16-amino-17-hydroxy compounds (type IV) are available.



Two kinds of copper(II) complexes are described: steroid/copper(II) = 2 : 1 for 16,17-trans compounds, steroid/copper(II) = 1 : 1 for 16,17-cis compounds.

P12.05.012 A STUDY OF THE ACTIVE SITES OF STEROIDAL RECEPTORS: THE 17-SPIRO LACTIDE OF HYDROCORTISONE. A.J. Mora, B.M. Ramírez, G. Delgado [1] R. Little [2], [1] Laboratorio de Cristalografía, Departamento de Química, Facultad de Ciencias, Universidad de Los Andes, Mérida 5101, Venezuela, [2] Laboratorio de Fisicoquímica Orgánica, Departamento de Química, Facultad de Ciencias, Universidad de Los Andes, Mérida 5101, Venezuela.

In the process of developing new soft drugs based on hydrocotisone, which are used as topical anti-inflammatory agents, the cyclic 17-spiro lactide modification in which the R groups of the 17a, 17b diesters are joined into one alkyl group was prepared as a mixture of epimers. The epimer, which has the absolute configuration R at the 6' -position, was investigated using X-ray diffraction. The compound, (6'R)-6'-methyl-2',5'-dioxo-(17R)spiro [11b-hydroxy-androst-4-en-3-one-17,3'-[1,4]-dioxane], of chemical formula $C_{23}H_{30}O_6$, is orthorhombic, space group $P2_12_12_1$ with a = 25.869(8) Å, b = 12.494(4) Å, c = 6.198(2) Å, V = 2003(1) Å^3, Z = 4, d_x = 1.334 g/Å^3.

The conformation of the steroid ring system is similar to those found for other hydrocortisone derivatives. The spiro lactide ring is in the half chair conformation, with its 6'-methyl substituent oriented towards the steroid ring, and the two polar esther carbonyl groups directly opposing each other. These two factors have an apparent detrimental effect to binding globulin if compared with the 6´-S epimer.

The molecules are held together by a hydrogen bond, which forms a zigzag pattern of chains parallel to the (010) direction.

This work was supported by CONICIT, grant S1-97000821, for the establishment of the Laboratorio Nacional de Difracción de Rayos-X, and CDCHT-ULA.

P12.05.013 [SECALONIC ACID D]$_3$FE$_2$, A SIDEROPHORE? C.L. Barnes and R.K. Murmann, Department of Chemistry, University of Missouri, Columbia, MO 65211, USA, R. Ubillas, Phytera, 377 Plantation St., Worcester, MA 01605, USA, M.S. Tempesta, Pharmaprint, 846 San Carlos Ave., El Granada, CA 94018, USA.

Secalonic acids A through G are dimeric hydroxanthone derivatives produced by a number of fungi commonly isolated from stored grains and animal feeds. Secalonic acid D (**SAD**), produced by *Penicillium oxalicum*, and arguably the most studied of this family of mycotoxins, is teratogenic and has been shown to cause cleft palate and other physical and behavioral deficits in test animals [1,2].

While it was early noted that the secalonic acids gave a wine-red color reaction with Fe^{3+}, the resulting complex has not before been characterised. Our X-ray crystal structure of the iron complex of **SAD** reveals a helical arrangement in which three **SAD** molecules chelate two Fe^{3+} cations with octahedral arrays of six O atoms. The O atoms about each iron center include three deprotonated phenolic O atoms to yield a neutral complex.

Most fungi produce siderophores, small molecular weight iron-binding molecules, under conditions of low iron stress. Typical fungal siderophores bind iron with an octahedral array of six O atoms, reminiscent of the **SAD**$_3$Fe$_2$ complex. To meet the definition of a classical siderophore, the biosynthesis of secalonic acid must be under stringent control by iron. We will culture *P. oxalicum* on defined media to see if **SAD** meets this criterion.

P12.05.014 CINCHONA ALKALOID INTERACTIONS WITH METAL ATOMS. B. J. Oleksyn, P. Pytel and J. Œliwiñski, Faculty of Chemistry, Jagiellonian University, R. Ingardena 3, 30-060 Kraków, Poland.

Malaria parasites, *Plasmodium sp.*, which live in mammalian erythrocytes feeding on their hemoglobin amino acids, are able to polymerize heme, poisonous for them in its water-soluble monomolecular form. Cinchona alkaloids are believed to interact with heme iron and block the formation of polymeric hemozoine which is the product of *Plasmodium* life processes. In view of difficulties in obtaining crystalline heme-alkaloid complexes we have undertaken systematic studies of Cinchona alkaloid interactions with different metal atoms in various coordination surroundings.

In the crystalline cinchoninium salts with tetrachlorocadmium and tetra-chlorocopper anions, described by us previously, metal atoms interact with alkaloid *via* coordinated chlorines which are proton acceptors in the intermolecular hydrogen bonds with quinuclidine nitrogen, N1. In the complex (HQ)$CoCl_3$, obtained recently by us from alkohol solution of $CoCl_2{\cdot}6H_2O$ and quinine (Q), cobalt atom is directly linked to N13 atom of the quinoline moiety (N13-Co = 2.070(2) Å) and to three chlorines. Cl atoms are acceptors of protons bonded to N1 and O12 atoms of Q. The conformation of Q is similar to that of the free base.

Co-Q interaction which occurs in (HQ)$CoCl_3$ is different from those observed e.g. in ruthenium complex with cinchonine [1] and osmium complex with a derivative of dihydroquinidine [2]. In the first of them metal atom is coordinated by N1 and O12 of the alkaloid molecule, while in the second - only by N1.

Crystal data for (HQ)$CoCl_3$: M.F.: $C_{20}H_{25}N_2O_2CoCl_3$, FW = 490.721, CuK_α, $P2_12_12_1$, a = 7.6262(4), b = 11.4902(8), c = 24.6214(9) Å, Z = 4, D_m = 1.52(1) gcm^{-3}, D_x = 1.50 gcm^{-3}, R1 = 0.0416 for 4290 $F_o > 4\sigma(F_o)$, *w*R2 = 0.1029, S =1.036.

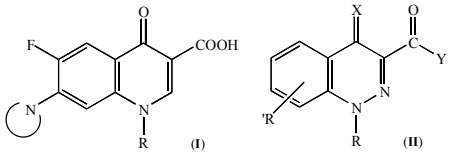
P12.05.015 STRUCTURAL STUDIES OF BAICALEIN, A PLANT FLAVONOID WITH BIOLOGICAL ACTIVITY. Pamela Constantinou, Ryan Meyer, Miriam Rossi, Department of Chemistry, Vassar College, Poughkeepsie, NY 12604-0484, USA and Francesco Caruso, Istituto di Strutturistica Chimica, CNR, CP#10, 00016, Monterotondo Stazione (Rome) Italy.

Many flavonoids are biologically active compounds that are ubiquitous in plants. Baicalein (5,6,7-trihydroxyflavone), $C_{15}O_5H_{10}$, is the principal component of a traditional Asian drug, Sho-saiko-to. The crystal and molecular structure reveal that baicalein exists in an almost planar conformation, with an 8° torsion angle about the single bond connecting the phenyl and the pyrone rings. The disposition of the hydroxyl groups is to maximize intramolecular hydrogen bonding and each of the hydroxyl hydrogen atoms is involved in a three-center hydrogen bonding situation involving inter- and intramolecular interactions. Two baicalein molecules exist as hydrogen bonded dimers related by an inversion center. There are also stacking interactions among the almost planar hydrogen bonded dimers. The stacking of the molecules is roughly perpendicular to the *c* axis in the *ab* plane. Studies in trying to clarify how baicalein interacts with proteins and nucleic acids will be described. Baicalein crystallizes in $P2_1/n$ with *a* = 7.907(4) Å, *b* = 13.367(5) Å, *c* = 12.911(6) Å, β = 117.26(2)°.

P12.05.016 NEW DETAILS OF ANTIBACTERIAL QUINOLONES ACTION DERIVED FROM THEIR CRYSTAL STRUCTURES. Marek L. Glówka and D. Martynowski, Institute of General and Ecological Chemistry, Technical University of Lódz, ul. Zwirki 36, 90-924 Lódz

The crucial structural requirements for antibacterial activity of a quinolone is N1-substituted 4-oxo-1,4-dihydroquinoline with an acidic function in the C3 position. 3-Carboxylic acids with cyclic amines (preferably piperazine and pyrrolidine) at C7 and a fluorine at C6 are the most common agents (I). Two main models of quinolones actions have been proposed, one based on their interactions with gyrase-DNA complex (by hydrogen bonds with guanine) and the other on intercalation with DNA. As a detailed molecular mechanism of antibacterial quinolones action is not known, structural information from crystal structures of quinolones and their analogs is very valuable. Over 20 crystal structures of quinolones may be found in CSD, which combined with 10 of cinnoline analogs (II) determined in our laboratory, gives a sound base for our observation of some patterns relevant to quinolones action. Our most important findings are: (*i*) quinolones show good permeability through cell membranes by ”locking” acidic hydrogen in 3-carboxylic group into an intramolecular hydrogen bond with 4-oxo substituent, (*ii*) preference for specific stacking

in crystal structure of quinolones suggests that particular DNA sequence is a target for quinolones and (*iii*) analogs of quinolones, designed by us to interact with a base complementary to guanine (cytosine), showed antibacterial activity similar to that of nalidixic acid.



P12.05.017 X-RAY POWDER DIFFRACTION STUDY OF CHITIN AND CHITOSAN OBTAINED WITH ENZYME PROCESSES. A.D.Zuev and A.Ertel, X-Ray Lab, University of Applied Sciences, 23562 Luebeck, Germany.

A biopolymer chitin, poly-ß-(1→4) linked N-acetyl-D-glycosamine, and especially its derivative chitosan prepared from chitin by acetylation n-acetyl-glycosamine units in strong alkali have a wide field of applications [1]. The structure of the most distributed α-chitin were determined with single crystal structure analysis in [2]. It belongs to the orthorhombic space group $P2_12_12_1$ with unit cell dimensions a=4.74Å, b=18.86Å, c=10.32Å. The powder chitin and particularly chitosan show the low crystallinity. The one of the alternative to the traditional acid-alkali way of the manufacture chitin/chitosan from shellfish waste is enzyme proceeding [3]. For the control of its quality the comparison of the X-ray powder diffraction diagram of the chitin from the different sources were made. The simulations of the powder data carried out with PowderCell [4] and FullProf [5] show that with enzyme method proceeding chitin is identified as α-chitin. The preliminary refinement with the program FullProf were made. The measurement were carried out with thin film too. Depending on the preparation method the thin films show different grads of the crystallinity up to the amorph state.

P12.05.018 STRUCTURAL STUDY OF NOVEL PYRIDONE DERIVATIVES: THREE POTENTIAL CARDIOVASCULAR AGENTS. M. Suárez[1], Y. Verdecia[1] , E. Ochoa[1], R. Pomes[2], J. Duque[2], H. Novoa[3], N. Blaton[4], O. M. Peeters[4]. [1]Laboratory of Organic Synthesis, Faculty. of Chemistry, Havana University, Cuba. [2]National Center for Scientific Research, Havana, Cuba. [3]Center of Pharmaceutical Chemistry. Havana, Cuba. [4]Katholieke Universiteit Leuven. Laboratorium voor Analytische Chemie en Medicinale Fysicochemie, Belgium.

In the aid of finding new cardiotonic agents, we developed the structural study of novel 2(1H)-pyridones derivatives of dihydropyridine-type.

	a (Å)	b (Å)	c (Å)	β (°)	Sp. Group	Final R.(%)	S
1	8.983(2)	13.196(3)	21.125(4)	90.00 (0)	Pcab	4.99	1.165
2	11.297(1)	6.949(1)	13.732(2)	91.95 (0)	$P2_1/c$	5.43	1.162
3	9.2810(4)	22.498(2)	7.5278(7)	113.06(4)	$P2_1/c$	4.66	1.056

The X-ray structure of compounds 1, 2 and 3 shows a skew-boat conformation for the pyridone ring, with the phenyl ring occupying a pseudo-axial position and is orthogonal to the mean plane of the pyridone ring. The lactone ring fused to the pyridone ring in 2 is perfectly plane and the fused cyclohexanone ring in 3 has a conformation close to an envelope. The molecules are linked by N-H···O hydrogen bonds forming dimers. The hydrogen bond is formed between the N-H group and the oxygen atom of the pyridone exocyclic carbonyl group for each compound.

P12.05.019 STRUCTURAL DETERMINATION OF 1-(4-X-BENZOYL)-3,3-DIMETHYLTHIOUREA. R. Pomes[1*], G. Aguero[2], A. M. Plutín[2], H. Márquez[2] and Y. I. Rodríguez[2]. [1]National Centre for Scientific Research, P.O. Box: 6880, Havana, Cuba. [2]Laboratory of Organic Synthesis, Faculty of Chemistry, Havana University, P.O. Box 10400, Havana, Cuba.

1-(X-benzoyl)-3,3-dimethylthioureas (X= Br, Cl and CH_3) are well recognised compounds because of their known applications in medicine and as bio-active and anticorrosive agents.

Structural studies of a number of benzoyl thioureas have proved them to be in the thioamidic form and to possess an intra-molecular hydrogen bond between N-H and the benzoyl oxygen.

Crystal and molecular structure of 1-(4-X-benzoyl)-3,3-dimethylthioureas have been determined by means of spectroscopic techniques such as IR, NMR ^1H, ^{13}C and X-Ray Diffraction.

	a (Å)	b (Å)	c (Å)	β (°)	Sp. Group	Final R.(%)	No. of Reflec.
Cl	11.175(1)	5.454(1)	8.056(2)	92.22 (1)	$P2_1/c$	4.1	2511
Br	11.308 (5)	5.578(5)	18.322(5)	91.88 (1)	$P2_1/c$	5.1	2600
CH_3	12.703 (3)	5.577(2)	17.389(4)	103.93(1)	$P2_1/c$	7.1	771

In the structures are present intra-molecular hydrogen bond N-H···S. The torsion angles between atoms O-2-3-4 and 1-2-3-4 vary with the X substituent.

P12.05.020 ABSOLUTE CONFIGURATION OF SECOND GENERATION ANTIMALARIAL ARTEMISININ COMPOUNDS. Jean M. Karle, Ai J. Lin, and Apurba K. Bhattacharjee, Departments of Pharmacology and Medicinal Chemistry, Division of Experimental Therapeutics, Walter Reed Army Institute of Research, Washington, DC 20307, U.S.A.

The artemisinin family of compounds is very important for the treatment of malaria due to their potency against chloroquine-, mefloquine-, and multidrug-resistant parasites. Artemisinin, the parent compound, is a sesquiterpene endoperoxide, naturally occurring in the Chinese herb *Artemisia annua*. Artelinic acid, a water soluble synthetic derivative, is currently in preclinical development. Artelinic acid derivatives were synthesized in the hopes of being more efficacious, possessing a longer plasma half-life, keeping the compound water soluble, and preventing enzymatic conversion to dihydroartemisinin, a known toxic metabolite of artemisinin analogs in rats and dogs. Crystal structures of diastereomeric methyl 4-(*p*-chlorophenyl)-4(*R* or *S*)-[10(α or β)-dihydroartemisininoxy]butyrates were determined to assign the absolute configuration and to provide an experimentally determined conformation. The x-ray structures are consistent with their proton nmr spectra suggesting that the crystalline and solution structures are similar. The most abundant and

thermodynamically stable conformations of the acid analogs of the butyrates at the 3-21G* level also match the crystalline conformations of the methyl esters. Enhanced antimalarial activity was achieved. However, the acid form of the *R*(β)-diastereomer is not very soluble in water. Computed electrostatic potentials indicate that the acid form of the *R*(β)-diastereomer is more lipophilic than artelinic acid. Computations also indicate that protonation of the ether oxygen atom requires more energy for the *R*(β)-diastereomer than artelinic acid suggesting a slower conversion than artelinic acid to dihydroartemisinin.

S(α)-diastereomer: $C_{26}H_{35}O_7Cl$, $P2_12_12_1$, a = 10.292(2), b = 15.663(3), c = 16.277(4) Å, Z = 4, V = 2623.91 Å^3, Cu K(α), *R1* = 0.0713, *wR2* = 0.3316.

R(β)-diastereomer: $C_{26}H_{35}O_7Cl$, $P2_1$, a = 9.715(1), b = 10.532(1), c = 27.821(2) Å, β = 92.29(1)°, Z = 4, V = 2844.33 Å^3, Cu K(α), *R1* = 0.1241, /.*wR2* = 0.3420.

P12.05.021 WATER MEDIATED HYDROGEN BONDING NETWORK IN AN ACRIDINE CARBOXAMIDE DERIVATIVE. J.Jeyakanthan and D.Velmurugan, Department of Crystallography and Biophysics, University of Madras, Guindy Campus, Chennai 600 025, INDIA, and Thainash Muthu Josephrajan and V.T. Ramakrishnan, Department of Organic Chemistry, University of Madras, Guindy Campus, Chennai 600 025, INDIA.

Acridine derivatives have general use in medicine, especially as antitumor agents and anti bacterial agents for wound therapy. The biological activity of the acridines are mainely due to its ability to interact with DNA. Acridine orange and 9-amino acridine are widely studied towards understanding their intercalating behaviour. In these derivative central ring (Pyridine) is approximately planar and the outer two rings adopt distorted half-chair conformations. The molecules are stabilized by many hydrogen bonds. The inter molecular -OH (hydroxyl group)....-C = O(keto) oxygen hydrogen bond makes a molecular chain along c axis. The inter-chain interactions (running along b axis) by water molecules makes a three dimensional hydrogen bonding network. Crystal data: C_{20} H_{20} O_5 N_2, a = 11.142(4), b = 12.266(2) and c = 13.320(2)Å, β = 91.76(2)º and V = 1819.6(1)Å^3, F.W = 368.4, Monoclinic, $P2_1$/ c and Z = 4. The final R = 0.052 and R_w = 0.15 for 3430 reflections (CuKα, λ = 1.5418Å). Structure solution : SHELXS97, Refinement SHELXL97. All conformational features will be presented.

P12.05.022 HYDROGEN BONDING ANALYSIS AND MOLECULAR CONFORMATION OF MONONUCLEAR COPPER AND MANGANESE COMPLEXES S. Shanmuga Sundara Raj, X-ray Crystallography Unit, School of Physics, Universiti Sains Malaysia, Penang, 11800, Malaysia

The function and properties of the active sites are determined by the environment and coordination sites around the metal ion. The Cu,Zn,Mn and Fe complexes are better model compound for metalloenzymes and proteins as they mimic the active site. A stable, non-toxic, low molecular weight mononuclear copper(II) and manganese(II) complex possess clinical applications. The metal ions are in square planar environment; the O and N atoms being the dentating centres with same kind of coordination. The water molecule and the perchlorate ions play major role in the packing by involving in intra- and inter molecular hydrogen bonds. The reported structures are isostructural.

Crystal data: I: $[C_{28}H_{38}N_4O_4Cu.2(CLO_4).H_2O]$, a = 8.9654(3) , b =9.6447(3) and c = 20.0666(5)Å, α=78.475(1), β = 81.518(1), γ=83.786(1)º and V = 1675.99(9)Å^3, triclinic, P-1 and Z = 2. R = 0.068 and R_w = 0.16 for 7898 reflections. II: $[C_{28}H_{38}N_4O_4Mn.2(CLO_4).H_2O]$, a = 8.9162(1), b =9.6764(1) and c = 20.0766(1)Å, α=78.536(1), β = 81.520(1), γ=83.922(1) º and V = 1673.79(3) Å^3, triclinic, P-1 and Z = 2. R = 0.064 and R_w = 0.19 for 6440 reflections. The complete details of the structure and the modelling studies will be reported.

P12.05.023 N-H…S AND C-H…π HYDROGEN BONDING IN THIOUREA DERIVATIVES. S. Shanmuga Sundara Raj,[a] D.Velmurugan[b] and Hoong Kun Fun[a], [a]X-ray Crystallography Unit, School of Physics, Universiti Sains Malaysia, Penang, 11800, Malaysia and [b]Department of Crystallography and Biophysics, University of Madras, Guindy Campus, Chennai 600 025, INDIA

The thiourea derivatives are found useful as rubber accelerators, intermediate materials in dye preparation and very useful agrochemical intermediates. Recently they were found to possess non-linear optical properties. The C-S bond distances show that the double bond nature and this may be influenced by the nature of the substituent group and in particular its ability to participate in π-conjugation. The phenyl ring makes a trans-cis orientation with the central bridge which favours the dimer formation among the molecules through an almost linear N-H...S intermolecular hydrogen bonding. The molecules are packed in a centrosymmetric manner forming two dimensional layer. The C_{sp}^2-H atom participates in π-interaction with the centroid of the other ring and there is an attraction between the centroids of the same rings oriented in opposite direction.

Crystal data: I: $[C_{15}H_{14}N_2OS]$, a = 8.4551(2), b = 8.9044(2) and c = 10.7293(3)Å, α = 91.142(1), β = 107.437(1), γ=113.035(1)º and V = 700.50(3)Å^3, triclinic, P-1 and Z = 2. S=0.93, R = 0.041 and R_w = 0.095 for 3325 reflections. II: $[C_{16}H_{16}N_2OS]$, a = 5.4664(1), b =28.0208(4) and c = 9.8585(1)Å, β = 94.262(1) º and V = 1505.88(4) Å^3, monoclinic, $P2_1/c$ and Z = 4. S=1.06, R = 0.053 and R_w = 0.16 for 3688 reflections. The data were collected on Siemens SMART CCD area detector diffractometer and solved by SHELXTL package. The complete details of the conformation and the hydrogen bonding will be presented..

06. CRYSTALLOGRAPHY OF ORGANIC COMPOUNDS

P05.06.001 MODIFIED CLUSTER VARIATION METHOD FOR PHASE DIAGRAM CALCULATION IN BINARY CRYSTAL STRUCTURES R.V. Chepulskyy [1] Department of Solid State Theory, Institute for Metal Physics, National Academy of Sciences of Ukraine, 36 Acad. Vernadsky Blvd., UA-252680 Kyiv-142, Ukraine

By the use of the radius of interatomic correlations as a small parameter in the cluster expansion, a modified cluster variation method is developed. The proposed method is applied for calculation of the short-range and long-range orders as well as phase diagrams in a number of two-component crystal structures. The high accuracy and high convergence of the method is demonstrated on the basis of comparison with the results of the Monte Carlo simulation.

The proposed modified cluster variation method is successfully applied for development of the inverse methods of calculation the many-body (including non-pair) interatomic correlations and interactions through the data on the diffuse scattering intensity and Mossbauer spectra of two-component crystal structures.

The developed methods can be used under investigation of alloys, low-dimensional lattice systems, semiconductors and magnetics.

P05.06.002 SOLID-STATE PHOTODIMERIZATION CONTROLLED BY THE BUFFER ZONE. N.Hirayama [1], N.Marubayashi, T.Ogawa [2], [1] Department of Biological Science and Technology, Tokai University, 317 Nishino, Numazu, Shizuoka 410-0321,Japan, [2] Research Laboratories, Yoshitomi Pharmaceutical Industries Ltd., 955 Koiwai, Yoshitomi-cho, Chikujo-gun, Fukuoka 871, Japan

Solid-state photodimerization of olefins is one of the well-known topochemical photodimerizations. On the basis of Schmidt's rule [1], it seems that bulky olefins should not undergo solid-state photodimerization due to the significant steric hindrance. We discovered that bulky olefins can undergo solid-state photo-dimerization in spite of a highly steric hindrance. Detailed inspection of the crystal structures revealed that there is a certain space between reacting molecules in the crystal to allow initiation of photodimerization. The space which is not necessarily located near the reaction site buffers the steric hindrance from which the reacting molecules suffer when they approach each other. The space, designated as buffer zone[2], is essential for the crystalline-state reactions. The role of the buffer zone in the crystalline-state reactions will be discussed.

P05.06.003 TAUTOMERISM OF A NITRO DERIVATIVE OF SALICYLIDENEANILINE IN CRYSTALS. T. Fujiwara and K. Ogawa, Department of Chemistry, Graduate School of Arts and Sciences, The University of Tokyo, Komaba, Meguro-ku, Tokyo, 153-8902 Japan

N-Salicylideneanilines belong to a class of the popular compounds which show thermo- or photochromism in crystals. Extensive studies have revealed that the chromisms are closely related to the tautomerism between the OH and NH forms and that most of *N*-salicylideneanilines including the parent compound (**1**) greatly favour the OH form in both crystals and solutions.[1] However, if a nitro group is introduced into the benzene ring of the salicylaldehyde part, the tautomeric behavior is changed significantly. For example, it was reported that *N*-(2-hydroxy-3-nitrobenzylidene)aniline (**2**) exists as the OH form in saturated-hydrocarbon solvents at room temperature but an aggregate at 77 K where the NH form is involved. The behaviour of **2** in crystals has, however, remained unknown. We report here the tautomerism of **2** in crystals on the basis of X-ray crystallography and electronic spectroscopy.

P05.06.004 SOLID STATE PHOTOREACTION OF 2-PYRONE DERIVATIVES WITH MALEIMIDES. M. Kawaminami, Department of Physics, Faculty of Science, Kagoshima University, Korimoto, Kagashima 890-0065, Japan. T. Obata, T. Shimo and K. Somekawa, Department of Applied Chemistry and Chemical Engineering, Faculty of Engineering, Kagoshima University, Korimoto, Kagoshima 890-0065, Japan.

Photoreaction of a 1:1 complex crystal of 4-methoxy-6-methyl-2-pyrone (**1**) with maleimide (**2**) gave [2+2]cycloadduct (**3**) peri-, site- and stereospecifically. It was inferred to be effectively brought by two sets of the hydrogen bonding and CT stacking between **1** and **2**.

Solid state photoreaction, 1:1 Complex crystal, Photocycloadduct

Photochemical reactions in the solid state afford unusual and interesting results because molecules are disposed tightly and regularly in the environment[1]. In this paper the solid state photocycloaddition reaction of **1** with **2** is described.

Irradiation of a 1:1 complex crystal between **1** and **2**, which was prepared by recrysrtallization of the equimolar substrates from acetonitrile, with a 400W high-pressure mercury lamp under nitrogen at room temperature gave [2+2]cycloadduct **3** in 54% yield as a sole product. On the other hand, the two starting materials in solution photoreaction afforded two kinds of products containing the cycloadduct **3** as a minor product. The crystal and experimental data of the 1:1 complex crystal of **1** with **2** are as follows: chemical formula=$C_{11}H_{11}NO_5$, crystal system = monoclinic, space group= $P2_1/n$, Z=4, lattice constant a=6.678(2), b=11.354(2), c=15.105(4), b_= 94.44(2), volume of unitcell V=1141.84, R=0.075, R_w=0.095.

The photochemical behavior can be readily interpreted by X-ray structure analysis of the 1:1 complex crystal. The molecular **1** is connected to another molecule **2** in the hydrogen bonding. The intermolecular distances of two facing double bonds between **1** and **2** are within the normal photoreaction distance in the solid state. The existence of the hydrogen bonding is also found to be necessary to the [2+2]cycloaddition in addition to the CT stacking in this system.

P05.06.006 COPOLYESTERS BY SOLID-STATE REACTION M. Siedler, M. Epple, Institute of Inorganic and Applied Chemistry, University of Hamburg, Martin-Luther-King-Platz 6, D-20146 Hamburg, Germany

Biodegradable polyesters like poly(hydroxyacetic acid) (polyglycolide) or poly(lactic acid) (polylactide) are of great importance in medicine and pharmaceutical technology. Especially in medicine, these polymers are employed as absorbable surgical sutures, devices for bone fracture internal fixation and as controlled drug-delivery systems. Fine-tuning of mechanical and biological properties is possible by chemical "mixing" of both polymers to copolymers. Conventionally, such polymers are produced by ring-opening polymerization of the corresponding cyclic diesters (dilactones).

Here we report on the formation of copolyesters of polyglycolide and polylactide in a solid-state reaction by simply heating mixed crystals of alkali halogenoacetates and alkali 2-halogenopropionates (e.g., sodium chloroacetate and sodium 2-chloropropionate). This reaction type is well known for the preparation of the pure polyesters: polyglycolide from halogenoacetates and polylactide from alkali 2-chloropropionate. During the reaction, an alkali halide (e.g., NaCl) is eliminated and the remainder of the molecule undergoes polymerization. Chemical composition, morphology and physical properties of a series of poly(lactide-co-glycolide) polymers were studied by X-ray powder diffraction, IR and NMR spectroscopy and viscosimetry.

P05.06.007 PREORGANIZATION EFFECTS IN SOLUTION AND SOLVENT FREE BISAMIDATION REACTION OF ALIPHATIC DIAMINOETHERS. Zofia Urbañczyk-Lipkowska, Institute of Organic Chemistry, Polish Academy of Sciences, 01-224 Warsaw, Poland

Preorganization between substrates and/or solvent molecules is leading factor in many organic reactions. Recently, it has been found that in some cases elimination of solvent allows for product formation with high yield and stereoselectivity [1]. The 1:1 reaction between aliphatic diaminoethers and active esters of aminoacids has been performed in protic (MeOH), polar aprotic (MeCN) and solvent free media. The composition of products (monoacylated diacylated and free amine) has been characterized and separation has been done using HPLC methodology. For comparison, reaction with various diamines was performed under the same conditions. Several products were characterized by X-ray structure analysis.

P05.06.008 NORRISH TYPE II PHOTOCHEMISTRY OF SPIRO-ADAMANTYL KETONES IN THE CRYSTALLINE STATE. Eugene Cheung, Matthew Netherton, John R. Scheffer, and James Trotter, Department of Chemistry, 2036 Main Mall, University of British Columbia, Vancouver, B.C., British Columbia, Canada, V6T 1Z1.

The photochemistry of a homologous series of spiro-adamantyl ketones (**1**) shows a range of Norrish type II reactions in the solid state. By obtaining the crystal structures of the reactants and using the Crystal Structure-Solid State Reactivity Correlation Method to analyze the geometry of each of the materials, we were able to rationalize the formation of the photoproducts. Parameters for γ-hydrogen abstraction were calculated and used to identify which ketones would yield Norrish type II biradicals that cleave and/or cyclize to the corresponding cyclobutanols. Crystal structure analysis also allowed rationalization of *endo*- or *exo*-aryl stereochemistry of the photoproducts.

The structures of the strained polycyclic photoproducts were confirmed by X-ray crystallography. In particular, irradiation of the six-membered ring spiro-adamantyl ketone gave an unexpected photoproduct, which is likely the result of a thermal rearrangement of the initial Norrish-Yang cyclization photoproduct.

P05.06.009 PHOTODIMERIZATION IN SINGLE CRYSTAL OF THYMINE DERIVATIVES HAVING LONG ALKYL CHAIN. N. Yasui[1], E. Mochizuki[1], N. Kanehisa[1], Y. Kai[1], N. Tohnai[2], Y. Inaki [2] and M. Miyata[2], [1]Department of Materials Chemistry, and [2]Department of Material & Life Science, Graduate School of Engineering, Osaka University, Suita, Osaka, 565-0871, Japan.

Thymine derivatives give photodimer upon irradiation with UV light near 280nm. The photodimer split to afford the original monomers very efficiently upon irradiation at a shorter wavelength (240 nm). In this study, the crystal structures of 1-octylthymine recrystallized from ethyl acetate and ethanol were determined by X-ray diffraction method. We report the relationship between the molecular orientation of thymine bases and the reactivity for photodimerization.

Crystal data for 1-octylthymine recrystallized from ethyl acetate (1): $C_{13}H_{22}N_2O_2$, monoclinic, space group $C2/c$, a=32.34(1), b=11.790(6), c=17.538(8)Å, β=112.65(2)°, V=6171(5)Å^3, Z=16 R=0.116. Crystal data for 1-octylthymine recrystallized from ethanol (2): $C_{13}H_{22}N_2O_2$, monoclinic, space group $P2_1/n$, a=15.11(1), b=12.115(4), c=16.471(5) Å, β=106.35(5)°, V=2894(2) Å^3, Z=8, R=0.083. The single crystal from ethyl acetate shows a very high photoreactivity, and gives only one stereo isomer (*trans-anti*) of the photodimer. But, the single crystal from ethanol does not give the photodimer. Both crystal structures are consisted of the hydrophilic layers of thymine bases and the hydrophobic layers of long alkyl groups. The thymine base of the crystal obtained from ethyl acetate faces another thymine base in the opposite plane with head-to-head, and the distance between two thymine bases is short to be able to photodimerize. In the crystal obtained from ethanol, however, the thymine bases are unsuitable orientation for the formation of the photodimer.

P05.06.010 PHASE SEQUENCE AND STRUCTURE ANALYSIS OF ß-CHLOROPIVALIC ACID C. Buhrmester and H. Fuess, Department of Materials Science, University of Technology Darmstadt, Petersenstr. 23, 64287 Darmstadt, Germany and S. Mason, Institut Laue-Langevin, Grenoble, France.

The existence of an ordered disordered phase or so called plastic phase has been established several decades ago. The ODIC phase for pivalic acid $(CH_3)_3COOH$ has been observed by Longueville et al. Extensive studies [1,2] indicated the temperature range between 308.5 K and 279.9 K for the ODIC phase. Further cooling does not lead to a complete ordered structure.

The substitution of one methyl group of pivalic acid leads to ß-chloropivalic acid $(CH_3)_2(CH_2Cl)COOH$. The influence of this substitution on the phase sequence and on the stability range of the plastic phase is at present under study.

Based on x-ray and neutron diffraction and thermal analysis four phases were detected. The phase range of phase I is only 4K (302K to 298K) and is isostructural to the plastic phase of pivalic acid; face centered cubic with Z=4 and a=8.84Å. Further cooling leads to phase II. The structure II is triclinic P-1 with Z=2, a=5.993(3)Å, b=6.042(4)Å, c=11.166(4)Å and α=98.49(4)°, ß=90.83(4), γ=115.71° at T=297K and reveals a disorder of the chlorine atoms establishing two conformers. At T=265K phase III is established. The phase transformation II↔III could only be seen by diffraction experiments and exists between 120K and 100K. Phases III and IV does not show significant structural differences. The structures are monoclinic $P2_1/m$ with Z=4 and a=6.332(2)Å, b=9.766(5)Å, c=10.931(6) Å and ß=97.94(2) at T=120K.

P05.06.011 NEUTRON DIFFRACTION STUDY OF THE 3-1 PHOTOISOMERIZATION OF 3-CYANOPROPYL COBALOXIME COMPLEX. T. Ohhara, J. Harada and Y. Ohashi, Department of Chemistry and Materials Science, Tokyo Institute of Technology, Meguro-ku, Tokyo 152-8551, Japan, I. Tanaka, S. Kumazawa and N. Niimura, Advanced Science Research Center, JAERI, Tokai-mura, Ibaraki 319-1195, Japan.

It was found that the (3-cyanopropyl)[(*R*)-1-phenylethylamine] cobaloxime complex isomerized to the 1-cyanopropyl cobaloxime on exposure to visible light with retention of the single crystal form. In addition, the produced 1-cyanopropyl group in this isomerization revealed high enantio-selectivity.

The X-ray structure analyses before and after the isomerization made clear the reason why the produced 1-cyanopropyl group showed high selectivity. However, the mechanism of this 3-1 isomerization remains equivocal. It must be made clear the intermediate structure, and the relationship between the enantio-selectivity and the hydrogen transfer in the process of the isomerization. The complex of (3-cyanopropyl-d_2^{α})[(*R*)-1-phenylethylamine]cobaloxime was prepared. To reduce the background of neutron scattering, the hydrogen atoms of (*R*)-1-phenylethylamine and cobaloxime moieties were replaced with the deuterium atoms. A crystal with dimension 3.5 x 3.5 x 0.7 mm was irradiated with a xenon lamp for 7 days and the crystal structure was analyzed by neutron diffraction at JAERI.

The analyzed structure indicated that the conversion ratio of the 3-1 isomerization was about 90%, and the 2-cyanopropyl group must be produced as an intermediate structure in the process of the isomerization. In addition, the D-C*-H chiral methylene group at the β-position of produced 1-cyanopropyl group was racemic. Stereo-selectivity of this chiral methylene can be considered to correlate with the stereochemistry of intermediate 2-cyanopropyl group, and further study is now in progress.

P05.06.012 HITTING THE BREAK! A STUDY ON THE CONFORMATIONAL BEHAVIOUR OF N-O BONDS. I. Svoboda, H. Fuess, J. Hartung, and M. Heubes. Fachbereich Materialwissenschaft, Fachgebiet Struktur-forschung, Technische Universität Darmstadt, Petersenstraße 23, D-64287 Darmstadt, Germany, and Institut für Organische Chemie, Universität Würzburg, Am Hubland, D-97074 Würzburg, Germany.

Rotations about N-O bonds are highly dynamic processes which are generally associated with low energy barriers. Energetic minima and maxima arise from superposition of (i) steric congestions between substituents at nitrogen and at oxygen and (ii) repulsion between doubly occupied nonbonding orbitals.

In order to separate two dynamic effects at nitrogen - rotation about neighbouring bonds and inversion at the central atom - *N*-alkoxy substituted fully unsaturated and therefore planar heterocyclic compounds were selected for the present study. Thus, *N*-(alkoxy)-4-*p*-chlorophenylthiazole-2(3*H*)-thiones and *N*-alkoxypyridine-2(1*H*)-thiones were prepared and studied by X-ray diffraction (T = 298 K), by variable temperature NMR (T = 130 K - 298 K), and by NOE-experiments in solution [1]. All compounds showed highly dynamic behaviour in solution at T = 298 K. Majorly populated conformers quickly interconverted by rotation about N-O bonds. This movement was shown to slow down significantly on cooling. At T = 130 K two distinct rotamers were observed. The solid state geometries of these compounds which were derived from X-ray diffraction are remeniscent to snapshots of low temperature NMR-experiments. Thus, 1:1 ratios of each rotamer were observed in the unit cell of every heterocyle. A correlation between energetic and steric parameters will be given and discussed in the present work.

P05.06.013 HYDROGEN CYANIDE (HCN) AND DCN. Göran Svensson, Inorganic Chemistry, Chalmers University of Technology, SE-412 96 Göteborg, Sweden.

Two crystal structures of solid HCN are known with a phase transition at about -100°C. The structure transforms from the orthorhombic space group Imm2 to the tetragonal I4mm, according to ref 1. The structure of HCN has been studied by several groups using various theoretical methods. These calculations often results in a structure where the HCN are arranged in parallel chains [2]. Parallel chains was also suggested from an early single crystal structure determination[1]. The energy difference between the parallel and anti-parallel models are, however, only a few kcal. In order to experimentally clarify if the chains are parallel or not, data have been collected from powder samples using neutron and synchrotron radiation. Data for both phases of HCN have been collected and the phase transition have been studied by synchrotron radiation. Neutron diffraction data sets for HCN at 140 and 193 K and DCN at 10 and 193 K were collected at the neutron reactor at Studsvik, Sweden. Synchrotron data have been collected with a image plate system at NSLS at Brookhaven National Laboratory, USA, and with a INEL CPS120 detector at MAX 2 in Lund, Sweden.

Analysis of the neutron data sets did not give a clear answer if the structure contains parallel or anti-parallel chains. Both models could be fitted equally well to the data sets. These results as well as results from the synchrotron radiation experiments will be presented.

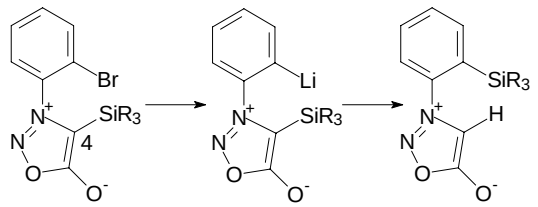
P05.06.014 A NOVEL REARRANGEMENT IN THE SELECTIVE SUBSTITUTION OF SILYL-PROTECTED O-BROMOPHENYL ARYLSYDNONES, David A. Grossie, Douglas M. Krein, and Kenneth Turnbull, Department of Chemistry, Wright State University, Dayton, Ohio 45435.

Sydnones are, in most cases, extremely stable crystalline compounds that exhibit a distinct polarity. The five-membered heterocyclic ring is subject to electrophilic substitution at the C-4 position. Only with a strongly activating group present will the 3-aryl group compete effectively for the electrophile, due to the considerable partial positive change at the 3-position of the sydnone ring. Accordingly, it is of interest to explore other avenues to arylsubstituted sydnones. Herein, we report on attempts to react selectively at the ortho position, leading to an interesting 1,5 silyl shift, as shown below.



R = Me_3, *i*-Pr_3, *t*-$BuMe_2$, *t*-$BuPh_2$

The precursors and products involving different silyl protecting agents have been examined by single-crystal X-ray diffraction and molecular mechanics in an attempt to understand the mechanism behind this rearrangement.

P05.06.015 INTERMOLECULAR INTERACTIONS OF $(C_5H_4R)Re(CO)Br_2L$ AND SOLID STATE REACTIVITY. Leanne Cook, D.C.Levendis, J.C.A. Boeyens, N.J. Coville, L.Cheng. Centre for Molecular Design, Chemistry Department, University of the Witwatersrand, Wits,2050, South Africa. e-mail: leanne@hobbes.gh.wits.ac.za

It has been demonstrated that the isomerisation of substituted cyclopentadienyl metal-dicarbonyl-dibromo "piano-stool" compounds [1,2] $(C_5H_4R)Re(CO)Br_2L$, is strongly dependent on the molecular environment. For example[1] when R = Me and L = CO isomerisation from the *diag* to the *lat* form occurs in the solid state (at about 105^0C). The reverse isomerisation does not occur in the solid state. However, in solution, the same complex undergoes only the reverse *lat* to *diag* isomerisation. When R = ^{t}Bu and L = CO, no solid state isomerisation is observed (although the *lat-diag* reaction still occurs in solution).

In addition to DSC and optical results, the X-ray crystal structures of several of these complexes have now been completed. The crystal and molecular structures and crystal packing have been modeled using molecular mechanics computer models[3]. In this paper, a summary of some of the recent crystallographic findings related to "piano-stool" complexes will be outlined, as well as some preliminary results of molecular and crystal packing modeling calculations.

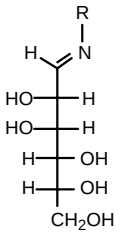
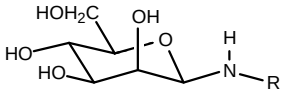
P06.06.001 SCHIFF'S BASES OR *N*-GLYCOSIDES: OPEN-CHAIN AND CYCLIC DERIVATIVES OF D-MANNOSE. William H. Ojala, Chemistry Department, University of St. Thomas, St. Paul, Minnesota 55105 USA; Charles R. Ojala and Joanne M. Ostman, Chemistry Department, Normandale Community College, Bloomington, Minnesota 55431 USA; William B. Gleason, Department of Laboratory Medicine and Pathology, University of Minnesota, Minneapolis, Minnesota 55455 USA

Reaction with ammonia derivatives converts monosaccharides into open-chain Schiff's bases in some cases and into cyclic *N*-glycosides in others. We have found D-mannose to show striking variability in this reaction. Previous investigations have shown the solid-state structures of its phenylhydrazone [1] and *p*-bromophenylhydrazone [2] to be open chains. Here we describe the structures of the derivatives formed from the reaction of D-mannose with three different nitrogenous bases. Reaction with hydroxylamine yields a conventional, open-chain oxime (**I**, R = OH). Reactions with semicarbazide and with *p*-chloroaniline yield cyclic *N*-glycosides (**II**, R = NH-C(O)-NH_2 and **III**, R = C_6H_4Cl).



I



II , III

The hydroxyl group of the oxime is *trans* with respect to the fully extended carbon chain. The semicarbazide derivative crystallizes as a dihydrate, the carbonyl group being linked intramolecularly to the O6 hydroxyl by a hydrogen-bonded bridge consisting of two water molecules. In both *N*-glycosides the substituent at C1 is located in the equatorial position (beta anomer).

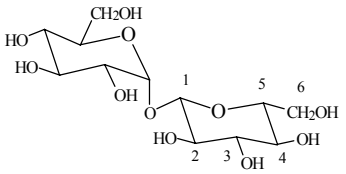
P06.06.002 TWO DERIVATIVES OF TREHALOSE. S.M. Clow and P.J. Cox, School of Pharmacy, The Robert Gordon University, Schoolhill, Aberdeen, AB10 1FR, Scotland and J.L. Wardell, Department of Chemistry, Aberdeen University, Meston Walk, Old Aberdeen, AB24 3UE, Scotland.

Trehalose (α-D-Glucopyranosyl-α-D-glucopyranoside) - shown below - is a naturally occurring disaccharide found in plants, insects, bacteria, yeasts and fungi. It supports anhydrobiosis (life without water) and can be used to preserve the structural integrity of biological assemblies on dehydration (1). In order to investigate its mode of action we have prepared derivatives in which the number of hydroxy groups have been varied.



X-ray data collected on the first derivative (which contains no -OH groups) were very weak (crystal size 0.21x0.10x0.10 mm) with only approximately 12% of the data with $I > 2\sigma I$. Restraints were applied to the anisotropic displacement parameters to achieve a successful refinement. The derivative crystallised in the space group $P2_12_12_1$ as the monohydrate.

Data for the second derivative (which contains one -OH group) were normal (crystal size 0.55x0.20x0.20 mm). This derivative crystallised in space group $P2_1$.

P06.06.003 STRUCTURAL ANALOGY BETWEEN β' TRIACYLGLYCEROLS AND *N*-ALKANES TOWARDS THE CRYSTAL STRUCTURE OF β'-2 P.P+2.P TRIACYLGLYCEROLS. Jacco van de Streek,[1,2] Paul Verwer,[1] René de Gelder[3] and Frank Hollander.[2] [1] CAOS/CAMM Center, [2] Department of Solid State Chemistry, [3] Crystallography Laboratory, University of Nijmegen, Toernooiveld 1, 6525 ED Nijmegen, The Netherlands.

Based on the analogy with *n*-alkane structures, a crystal structure for β'-2 1,3-dicaproyl-2-lauroylglycerol is proposed. The structural elements of the β'-2 polymorph of 1,3-dilauroyl-2-

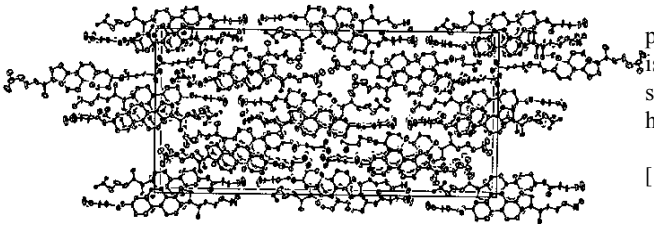
myristoylglycerol as found by Birker *et al*. were also observed in the crystal structures of other long chain compounds. This analogy led to the assembly of a β'-2 structure at atomic level from known crystallographic data. The structure was optimized by molecular mechanics and was consistent with experimental data, including satisfactory reproduction of the X-ray powder pattern. To the best of our knowledge, this is the first β' structure with a 1,2 configuration and an intramolecular orthorhombic subcell which was fully optimized by molecular mechanics to date. It shows all structural elements found earlier by Birker *et al*.

Birker, P.J.M.W.L., De Jong, S., Roijers, E.C. & Van Soest, T.C. (1991). *J. Am. Oil Chem. Soc.* **68**, 895-906.

P06.06.004 CRYSTAL STRUCTURE OF CHOLESTERYL HEMISUCCINATE. Young-Ja Park, Department of Chemistry, Sook Myung Women's University, Seoul 140-742, KOREA

Crystals of cholesteryl hemisuccinate($C_{31}H_{50}O_4$) are orthorhombic, space group $P2_12_12_1$, with *a*=9.371(5), *b*=24.434(12), *c*=50.491(20), having four molecules in an asymmetric unit. The crystal structure has been determined by the direct method using SnB program and refined by Fourier and full matrix least-squares methods. The R facor is 0.13 for 7815 observed reflections collected on a Nonius CAD-4 diffractometer with Mo-Kα radiation to a maximum 2θ value of 44.

Cholesteryl hemisuccinate belongs to the layer type crystal structure as in cholesteryl hexanoate, hexyl carbonate, octanoate, oleate and linolelaidate. At the center of the layer there is an interlocking arrangement of cholesteryl groups. The molecular long axes of all 4 symmetrically independent molecules are parallel to the *c*-axis and these molecules stack along 2_1 screw axes. The crystal has the liquid crystalline phase. The cholesteric phases are formed at 186.8 and melts at 194.3 to form an isotropic liquid.

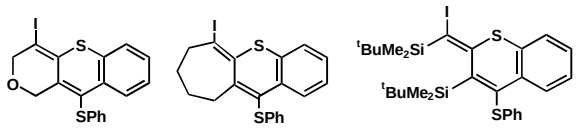


P06.06.005 CRYSTAL STRUCTURES OF GLYCOLIPIDS. Yutaka Abe[1], Takamitsu Tamura,[1] Masami Fujiwara,[1] Kazuo Ohbu,[1] and Kazuaki Harata,[2] 1:Material Science Research Center, Lion Corp., 7-13-12 Hirai Edogawa-ku Tokyo, Japan, 2:National Institute of Bioscience and Human-Technology, 1-1Higashi Tsukuba Ibaraki, Japan.

Crystal structures of model glycolipids, methyl 6-O-acylglycosides were investigated. An glycolipid including a sugar moiety as a hydrophilic group is important as a type of material in cell membrane and as a surfactant for dissolving and crystallizing of membrane proteins. Physico-chemical properties of the amphiphiles are affected by types of the sugar moieties. The crystal structures of glycolipids are known for acylglycoamides, glyconic amides and alkyl glycosides. Hydrophobic and hydrophilic layers like a cell membrane are formed by these crystals. The crystals are characterized by the hydrogen bonding systems between sugar moieties. The thermal stability of a crystal is significantly affected by the type of sugar moiety. Since the difficulty of crystallization of those amphiphiles, there is no systematic study to relate between the crystal structures and physico-chemical properties. We have investigated the crystal structures of methyl 6-O-acylglycosides having types of sugar moieties, methyl α and β-glucosides and α and β-galactosides, respectively with various length of alkyl chains. Each crystal with a type of sugar moiety has a crystal packing with a hydrogen bonding system. The hydrogen bonding system significantly affects to the crystal stability. The crystals of the α-galacotosides have infinite hydrogen bonding linkage in contrast of the finite linkage in those of β-glucosides. The crystals of α-glucosides have a disorder structure of the sugar moieties. The importance of the hydrogen bonding system to the thermal stability was shown by evaluation of packing energy of the crystals with molecular mechanics.

P06.06.006 A NOVEL DOMINO REACTION: STRUCTURAL X-RAYS STUDIES. E. García-Rodríguez and S. García-Granda, Physical and Analytical Chemistry Department, University of Oviedo, E-33071 Oviedo, Spain and L.J. Álvarez-García; I. Llorente; J.M. González; G.P. Romanelli, J. Barluenga, Instituto Universitario de Química Organometálica "Enrique Moles", Unidad asociada al CSIC, University of Oviedo, E-33071 Oviedo, Spain.

It has been recently shown [1] that terminal alkynes modified by a phenylsulfide substituent can be coupled, either intra- or intermolecularly, to yield condensed thiin structures upon reaction with IPy_2BF_4. X-ray analysis was used to ultimately determine the structure of some of the resulting heterocycles, as for instance:



(1) (2) (3)

The structural analysis, including intermolecular and packing interactions, will be discussed. Interestingly compound 3 is severely distorted from planarity as revealed by its molecular structure from X ray data, thus presenting an unexpected source of helical chirality [2].

P06.06.007 THE CRYSTAL AND MOLECULAR STRUCTURE OF 2,2', 4,4', 6,6'-HEXAMETHYL-BIS 4,4'-(4H)-PYRANE, $C_{16}H_{22}O_2$. S. A. Chawdhury, The University of Asia Pacific

The title compound results from the action of strong organic reducing agents on the 2,4, 6 - trimethy1 pyrylium cation (Conrow and Radlick, 1961). The substance is very non-polar and the two bipyran rings are linked by a single bond. NMR and spectroscopic measurements failed to prove unambiguously the exact nature of the molecule.

The molecule lies on the centre of symmetry. Moreover, the molecule has its own symmetry, 2/m with two fold axis nearly parallel to [122] direction. R. M. S. deviation of atomic positions from the 2/m symmetry is about 0.01 Å. The pyrane ring is planar, the maximum displacement being about 0.04 Å for 0 atom from the best plane passing through all the other atoms of the ring.

P06.06.009 CRYSTAL STRUCTURE OF 5-AMINO-4-(4-METHOXYPHENYL)-2-PHENYL-7-(PYRROLIDIN-1-YL)-1,6-NAPHTHYRIDINE-8-CARBONITRILE.
R.Sankaranarayanan and D.Velmurugan, Department of Crystallography and Biophysics, Univesity of Madras, Guindy Campus, Chennai-600 025, INDIA, S.S.S.Raj and H.K.Fun, School of Physics, Universiti Sains Malaysia, 11800 USM, Penang, MALAYSIA and V.Raghukumar and V.T.Ramakrishnan, Department of Organic Chemistry, University of Madras, Guindy Campus, Chennai - 600 025, INDIA.

The naphthyridine derivatives are known to exhibit wide range of biological activities such as bactericidal, fungicidal, anti-inflammatory, anti-convulsant and insecticidal activities. They are also known to possess lasing action. In the title compound studied, interestingly, there are two molecules in an asymmetric unit. The naphthyridine moiety in both the molecules are folded. The pyrrolidine rings adopt half-chair conformation. The molecular packing is stabilised by C-H...N type hydrogen bonds. Crystal data : $C_{26}N_5OH_{23}$, Triclinic, P-1, λ=0.71703Å, a=9.6808(1)Å, b=11.4468(2)Å, c=19.8557(1)Å, α = 100.047(1)° , β = 95.804(1)°, γ = 90.318(1)°, Z=4, F(000)=888, R [I>2σ(I)] = 0.062, R_w = 0.13, Observed reflections = 6085, Structure solution program:SHELXS97, Refinement program: SHELXL97. The conformational features will be presented in detail.

P06.06.010 COMBINATION OF ENERGY MINIMIZ-ATION AND VECTOR SEARCH METHODS USING DIRDIF PROCEDURES: STRUCTURE SOLUTION OF BENZOPYRANS. L.Vijayalakshmi and V. Parthasarathi, Department of Physics, Bharathidasan University, Tiruchirapalli, India.

The connectivity scheme of the compound was generated and its geometry was optimized by energy minimization using MOPAC 6.0 program. This molecule was used as the input to the orient option of the DIRDIF(Beurskens et al., 1996) program which uses the Nordman vector search rotation functions to orient the molecule to give maximum consistency with the Patterson function. The resulting set of atomic parameters is used for the translation function in DIRDIF fourier space. The resulting shift vector, if any, is applied to the atomic parameters and the correctly positioned molecule is used to phase a weighted Fourier synthesis. The procedure was adopted to solve the compounds namely, 4-(2'-(4''-methyl thiophenyl)ethenyl)-3-cyano-2H-1-benzopyran-2-one; 4-(2'-(1"-naphthyl)ethenyl)-3-cyano-2H-1-benzopyran-2-one and 6-methyl-4-(2'-(1''-naphthyl)ethenyl)-3-cyano-2H-1-benzopyran-2-one. Thereafter the structures were refined by SHELXL-97 program successfully to a final value of 0.05, 0.03 and 0.06 respectively.

Thailambal, V. G. and Vasantha Pattabhi (1986). Acta Cryst. C42, 1017-1019.
Beurskens, P. T. , Gezina Beurskens., Bosman, W. P., Rene de Gelder., Garcia Granda, S., Gould, R. O., Israel, R. and Smits, J. M. M. (1996). DIRDIF-96. Direct Methods Applied to Difference Structure factors, 1-665.

P06.06.011 THE CRYSTAL STRUCTURE ANALYSIS OF 2,7DIOXA[3,4BENZO(5,6COUMARINO)]DECALIN. R. Krishna[a] D.Velmurugan[a] S.Sanmuga Sundara Raj[b] and H.K. Fun [b] a Department of Crystallography and Biophysics, University ofMadras, Guindy campus, Chennai -25, India. b X-ray Crystallographic unit, School of Physics, Universiti sainsMalaysia, 11800 USM Penang, Malaysia.

Coumarin derivatives occuring in plants have differentbiological activities. Some synthetic modifications of natural coumarinslike acsculamin, folescutol are of pharmacological importance. Coumarin and its derivatives are used in oral anticoagulation therapy. The crystal structure of 2, 7 dioxa [3,4-benzo-(5,6-coumarino)]decalin has been determined by X-ray analysis. The cell parameters are: a = 12.225(1) Å b = 16.335(1) Å c = 15.340(2) Å , β = 109.21(1) °. The system is monoclinic with space group $P2_1/c$ and the final R-factor = 0.046. The structure consists of a coumarin moiety and three six membered rings. The coumarinmoiety is in planar conformation. The structure is completelystabilized by C-H...O type intermolecular interactions. Other geomentrical features will be presented in theposter.

P06.06.012 CRYSTAL STRUCTURE AND MO CALCULATIONS OF CONDENSED BENZENIC 1,2,5-THIADIAZOLE DERIVATIVES. E.E. Castellano, Inst. Física de São Carlos, Univ. de São Paulo, C.P. 369, 13560 São Carlos (SP), Brazil, and O.E. Piro, Dept. Física, Ftad. C. Exactas (FCE), Univ. Nacional de La Plata (UNLP), C.C. 67, 1900 La Plata, Argentina, and J.A. Caram, M.V. Mirífico and E.J. Vasini, INIFTA (CONICET), UNLP, C.C. 16, 1900 La Plata, Argentina and M.D. Glossman, CEQUINOR (CONICET), Dept. Química, FCE, UNLP, C.C. 962, 1900 La Plata, Argentina.

The 1,2,5-thiadiazoles have been broadly applied in pharmaceutical, agricultural, industrial and polymer chemistry. The potential pharmacologic applications include antibiotics, histamine H_2-receptor antagonists and β-adrenergic blocking agents. A number of other thiadiazoles have been found that are active as fungicides, bactericides, herbicides, plant-growth regulators and insecticides. Furthermore, the 1,2,5-thiadiazole ring has been incorporated into the backbone of a number of polymers with desirable chemical and thermal stability. As part of physical chemistry studies on several 3,4 substituted 1,1-dioxide derivatives of 1,2,5-thiadiazole, we report here a single crystal X-ray diffraction study on the molecular structure of the following derivatives: phenantro[9,10-c]-1,2,5-thiadiazole 1,1-dioxide (I) and acetonaphto[1,2-c] 1,2,5-thiadiazole 1,1-dioxide (II). We shall also report *ab initio* HF/6-31G** Hartree-Fock-LCAO molecular orbital (MO) calculations on the electronic structure, conformation and reactivity of compounds I and II, as well as results of a charge sensitivity analysis performed by resorting to several concepts derived from density functional theory.

P06.06.013 EXPERIMENTAL AND HEORETICAL DETERMINATION OF THE STRUCTURE OF 2 ,7 - NAPHTHALENE – DIOL. N.A. Ahmed, E. El-Kholy, S.M. El-Derby, R.H. El-Oraini, Physics Department, National Research Center, Dokki, Cairo, Egypt.

The crystal and molecular structures of 2,7 -naphthalene diol were determined experimentally by x-ray diffraction. Three-dimensional data obtained from equi-inclination Weissenberg photographs was obtained using Cu k_α radiation. The structure was solved by the direct method using the program Shelxs-86 and refined by the method of least squares using the full matrix program Shelxl-93 up to a value of R1=0.0563**.** The molecule is planar and the oxygen atoms are out of the molecular plane by 0.01 Aº on opposite sides of the plane.

The theoretical structure was calculated by the method of atom-atom potentials. Minimization of the lattice energy gave lowest value of minimum energy for the completely planar molecule. The atomic coordinates are comparable with those obtained experimentally.

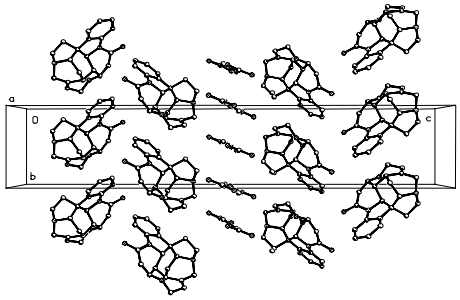
P06.06.014 CRYSTAL STRUCTURE OF 3-CHLORO-2(N-(4-CHLORO-2-METHYL) PHENYL)FORMIMIDOYL INDOLE. D. Velmurugan and R.Krishna, Department of Crystallography and Biophysics, University of Madras, Chennai - 25, India

Indoles show interesting chemical and biological activities. They act as anti-inflammatory, anti-bacterial, and analgesic agents. They also intercalate with DNA. The crystal structure of the title compound has been determined. The compound crystallizes in monoclinic system with space group $P2_1$. The cell dimensions are : a =4.670(1) Å, b=9.930(2) Å, c= 15.360(3) Å and $\beta = 97.8(1)°$. The structure was solved by direct methods and refined by full matrix least squares to a final R-value of 0.053 with 1370 unique reflections. The angle between the mean planes of the indole moiety and the phenyl ring is 20.6(1)°. Amino(or) amide N-H...π (aromatic) interaction has recently been theoretically postulated in model system and experimentally described in globular proteins. It has also been suggested that such interactions may provide stability, contribute to the folding process, and (or) have a functional role in proteins. N-H..π hydrogen bond is uncommon because it occurs only in acceptor-poor systems. Such non conventional aromatic hydrogen bonds are currently under intense investigation in structural biology. The above structure has a weak N-H...π intermolecular hydrogen bond. The other conformational details and a comparison of this structure with two related indole compounds will be described in the poster.

P06.06.015 CRYSTAL STRUCTURE OF N-CYCLOHEXYL-2-BENZOYL 4,5-DIPHENYL PYRROLIDINO SPIRO-[3-3']-H'-CHROMANONE. S.Thinagar and D.Velmurugan, Department of Crystallography and Biophysics, University of Madras, Guindy campus, Chennai 600 025, India.

3-phenyl chromanone is the skeleton for Isoflavonoids which are found in the plants of sub-family papilionoidae of Leguminosae. They are known to possess antifungal and antibacterial properties. Crystal data of the title compound : Monoclinic, Space group - $P2_1/c$, a = 14.021(3) Å, b = 18.682(4) Å, c= 11.362(2)Å, $\beta = 95.75(3)°$, R-value = 0.066. The two phenyl rings directly attached to the pyrrolidine ring are nearly perpendicular to it. The keto group containing the ring of the chromanone moiety adopts a half-chair conformation while the cyclohexane ring attached to the pyrrolidine ring adopts a chair conformation. The best plane passing through the chromanone moiety makes a dihedral angle of 82.2(3)° with pyrrolidine ring. The molecule is stabilized by one intra and two inter molecular C-H...O hydrogen bonds. The other structural features will be discussed in detail.

P06.06.016 CRYSTAL AND MOLECULAR STRUCTURES OF SOME ACRIDINONE DERIVATIVES. M.S.Kumar, D.Kumaran and M.N.Ponnuswamy Department of Crystallography and Biophysics, University of Madras, Guindy Campus, Chennai – 600 025, India.



The biological activity of acridine derivatives is often manifest in their mutagenic properties. Interestingly these derivatives intercalate with DNA. The principle behind is the planar chromophore common to the acridines which involve in stacking interactions with the pyrimidine-purine base pairs. This objective has received support from a large body of physical and biological data. A series of acridinone derivatives have been synthesized by a novel method and the structures are determined by crystallographic methods. In halide derivatives, the study reveals the electronic effect of chloro and fluoro substitution on the acridinone ring system geometry and the stacking properties of the planar chromophores. The central ring of the acridinedione moiety deviates from planarity. The molecules are stabilized by weak C-H...O interactions in addition to the van der Waals forces.

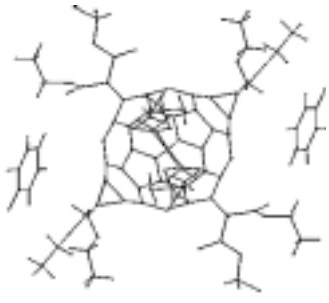
P06.06.017 A NEW CRYSTAL MODIFICATION FOR DIPHENYLPICRYLHYDRAZINE. M. Gary Newton, Department of Chemistry, University of Georgia, Athens, GA; John P. Rose, B.-C. Wang, Zhi-Jie Liu, Georgia X-ray Crystallography Center, University of Georgia, Athens, GA; Róbert Tuba and Ferenc Ungváry, Department of Organic Chemistry, Univ. of Vesprém and Research Center for Petrochemistry of the Hungarian Academy of Sciences, Vesprém, Hungary.

The reaction of diphenylpicrylhydrazyl radical with dicobalt octacarbonyl produced a crystalline product, which has now been identified as diphenylpicrylhydrazine (DPPH) via single-crystal X-ray diffraction. The crystals were monoclinic with a=25.814(1), b=10.7440(4), c=26.6230(7) Å and β=106.98(2)°, Z=16. The space group was determined as C2/c from systematic absences and from the successful structure solution. Diffraction data were measured to Θ=65° on a Bruker 2x2K CCD detector system; data were processed using SMART and SAINT data analysis systems. The structure was solved and refined using the program suite in TEXSAN. R=5.7%, Rw=5.3%.

A search of the Cambridge database did not find any report of the current monoclinic modification of DPPH. There are four previous reports of structural investigations of DPPH; all but one contains an included molecule of solvent. No coordinates were determined for the solvent-free system, reported as space group R-3. The two DPPH structures for which coordinates exist belong to space group R-3 and contain a cylindrical cavity at special positions in the cell which are filled with disordered solvent molecules, specifically THF and CHCl3. [H. Wang et al., J. Inclusion Phnom. 10, 203, 1991]. An early report of preliminary Weissenberg data describes a crystal of DPPH·benzene solvate in space group $P2_1$ but no structural coordinates were provided. [Ellison and Holmberg, Acta Cryst., 13, 446, 1960]. Thus, the current monoclinic crystals of DPPH apparently represent a new crystal modification.

Many features of the previously reported structures are found in the current modification. Particularly notable is a strong H-bond between the hydrazine NH and an O of an ortho-nitro group; the other ortho-nitro group is rotated considerably out of the picryl group plane. The para-nitro group is co-planar with the picryl group. A comparison of packings and cavity sizes will be discussed as part of the presentation.

P06.06.018 PACKING MOTIFS IN STRYCHNINE SALTS. Robert O. Gould, Caroline Dick, Fokke J.J. Dijksma, Simon Parsons, Sonja Schwarzl, Paul Taylor and Malcolm D. Walkinshaw Department of Chemistry and Institute for Cell and Molecular Biology, The University of Edinburgh, Edinburgh EH9 3JJ, United Kingdom.



Strychnine alkaloids have long been used as resolving agents for chiral organic molecules. We have recently reported data on the commonest packing modes of brucine, dimethoxystrychnine, which is the alkaloid in this series most commonly employed [1]. Strychnine itself is less successful at chiral recognition, and we now report the packing motifs of strychnine with several simple organic anions. The puckered monolayers seen in most brucine structures are absent here, and the commonest motif appear to be the bilayer shown above in plan. The unit mesh of these bilayers is approximately 7.6 x 7.6 Å, and they pack such that the polar parts of the molecules are directed outward towards a layer containing counterions and water. The overall effect is a surface less flexible and less complex that that shown by brucine.

1. Dijksma, Gould, Parsons, Taylor and Walkinshaw, *Chem. Commun.***1998**, 745-746

P08.06.001 PSEUDOSYMMETRY IN FULLERENE COMPOUNDS V.V. Gritsenko and O.A. Dyachenko, Institute for Chemical Physics Research, Russian Academy of Sciences, Chernogolovka, Moscow Region, 142432 Russia

An X-ray diffraction analysis was used to examine the structures of the fullerene compounds: $(Ph_4P)_2C_{60}Hal$ (Hal = Br (1) and I (2)), $(Ph_4As)_2C_{60}Cl$ (3) [1],$(C_{70})_3(BNDY)_4(C_6H_6)_4$ (BNDY — binaphtho [1.6-d,e]-1,3-dithiin-2-ilidene) (4), $C_{60}2[(Ph)_3PAuCl]$ (5). The presence of pseudosymmetry in the crystal structures of 1—5 is their specific feature.

In the course of our work on the study of the fullerene compounds [1], we found that the pseudosymmetry was characteristic of the crystal structures of 1—5. The positions of $(Ph_4P)^+$ or $(Ph_4As)^+$ cations and Br^- or I^- anions in the salts 1—3 conformed to the tetragonal space group, *I4/m*, in which the *4/m* centers and C_{60} centers coincided, that conflicting with the inherent Ih symmetry of fullerene. The structure was determined in space group $C\bar{1}$ [1]. In complex 4, the positions of the BNDY molecules and C_6H_6 solvates corresponded to the $P4_2/nm$ space group, in which a part of the independent fullerenes should lie on the $\bar{4}$ axis. In this case, that should also disturb their own symmetry. The structure was solved in the $P4_2mc$ space group, in which C_{70} were localized on axes 4_2 and *2*. In complex 5, the positions of the fullerene atoms answered the $R\bar{3}m$ space group, while the positions of the $(Ph_3)PAuCl$ molecules corresponded only to *P3*. The structure was solved in the *P3* space group. We believe that the pseudosymmetry in the crystals of compounds C_{60} and C_{70} is the consequence of the high inherent symmetry of the fullerene molecules, as well as of the presence of some disordering in them in the structures. Neglecting the presence of the pseudosymmetry in the crystals based on C_{60} leads to the errors in structure determination [2,3].

P08.06.002 STRUCTURE AND CHARGE DENSITY STUDIES OF A C_{60}-FULLERENE DERIVATIVE WITH DIFFERENT SOLVENTS. D.Zobel, M.Strumpel, P.Bombicz, M.Weber, R.Flaig & P.Luger, Institut fur Kristallographie, Freie Universitat Berlin, Takustr. 6, D-14195 Berlin

X-ray data of a hexa-cyclo substituted C_{60}-fullerene, co-crystallized with (a) 1,2 difluorobenzene and (b) with 1,2 dichlorobenzene, were collected with synchrotron radiation at 100 K and with conventional MoKα-radiation at 120 K respectively, using CCD area detectors (Bruker-AXS) in both cases. The molecules were compared to each other and to the same compound crystallized from bromobenzene by Hirsch et al.[1].The C_{60}-cage distortion data were compared to those listed in Zobel et al.[2].

Charge density maps could be generated from the synchrotron data set of (a) confirming the difference in bond electron density maxima between the 6-6 bonds with double bond character and the 5-6 bonds with single bond character within the C_{60}-cage. In addition typical "banana bent" bonds were observed on the bridging cyclopropane rings of the substituent moiety. Also *Ab initio* calculations were carried out on the C_{60}-cage and on the cage includingparts of the substituents with Gaussian 94.These results were compared to the experimental data. The picture shows the molecular structure of dodecakis-(ethoxycarbonyl)-[C60]-fullerene with 1,2 difluorobenzene (a).

We thank the Deutsche Forschungsgemeinschaft for financial support.

P08.06.003 WHY FULLERENE STRUCTURES ARE BAD? NEW RESULTS OF X-RAY DIFFRACTION STUDIES. Y.L.Slovokhotov[*], I.S.Neretin[*], Y.V.Zubavichus[*], A.S.Batsanov[**], J.A.K.Howard[**], [*] Institute of Organoelement Compounds R.A.S., Moscow, Russia, [**] Department of Chemistry, University of Durham, Durham, UK

Molecular geometry and packing in $C_{60}\cdot 2PhX$ (I; X=Me,Br), $C_{70}\cdot 2(o\text{-xylene})$ (II), $C_{60}\cdot$tripticene (III), $C_{60}Ir(CO)(PPh_3)_2Cl\cdot solv$ (IV) $C_{60}\cdot$(4-benzoyl-3-Me-1-Ph-pyrazolone) (V), and $2C_{60}\cdot$(tetraphenylporphyrine)$\cdot(2.33+x)C_6H_6$ (VI), are discussed on the basis of single crystal X-ray data. Positions of solvent molecules and the rotational disorder of fullerene moieties are analysed. Hexagonal layers (I), double layers (II), honeycomb layers with $Ir(CO)(PPh_3)_2Cl$ fragment in between, and three-dimensional networks of fullerene molecules (III,V,VI) were found in these complexes, with donor and solvent molecules in the cavities.

Powder XRD data for I-III,V as well as for simple solvates $C_{60,70}\cdot 2o\text{-}C_6H_4X_2$ (X=Me,Cl) and $2C_{60}\cdot$arene (with mesitylene and $m\text{-}C_6H_4X_2$, X=Me,Cl), were collected. Due to a poor reflectivity of the samples, SR data were used for IV (Daresbury Laboratory) and several solvates (Siberian SR Centre). Powder patterns calculated from the atomic positions and simulated using single crystal *I(hkl)* datasets, are compared with the experimental ones.

The highly anisotropic mosaic spread of stacked crystal blocks in fullerene derivatives results in anisotropic extinction that distorts *both* the powder *and* the single-crystal diffraction intensities. The resulting biased statistics of *E*'s (rather than a dynamics on the molecular level) dictates a poor quality of many "fullerene" datasets and hinders a routine phase determination in direct methods. This problem is discussed on the examples of V and VI; some remedies are suggested.

P08.06.004 SUPRAMOLECULAR ARCHITECTURE OF CROWN ETHER STYRYL DYES FROM X-RAY CRYSTAL STRUCTURE ANALYSIS. G.G. Alexandrov, L.G. Kuz'mina, A.V. Churakov, Institute of General and Inorganic Chemistry, Russian Academy of Sciences, Leninskii pr. 31, Moscow 117907, Russia, and J.A.K. Howard, Chemistry Department, University of Durham, Durham DH1 3LE, UK

The crystal packing of aza- and benzocrown ether dyes of benzothiazolinium and quinolinium series is analyzed based on our X-ray structural results. All of the crystals contain stacks of

the conjugated dye molecules with a “head-to-tail” or “head-to-head” mutual arrangement. Very loosely packed channels and layers of crown ether moieties are also typical for these single crystals. In the head-to-tail stacks, the ethylene fragments of two adjacent, centrally symmetrically related dye molecules are closely spaced (the C...C distances are about 3.5 A). This arrangement is favorable for the photochemical [2+2] cycloaddition reaction characteristic of these compounds in solutions and films. The very flexible environment of these ethylene pairs in the crystal represented by crown ether channels makes it possible to suggest that the above-mentioned reaction can proceed in the single crystal at least in its separate regions.

We thank the Russian Foundation for Basic Research for funding this work (project number 98-03-33142).

P08.06.005 ENANTIOMERIC RECOGNITION OF (R)- AND (S)-ALPHA-(NAPHTHYL)-ETHYLAMINE BY CROWN ETHERS. T. Gérczei, Z. Böcskei [1], G. M. Keserû [2], P. Huszthy [3], [1] Department of Theoretical Chemistry, Eötvös University, H-1518 Budapest 112. POB 32., Hungary, [2] Department of Chemical Information Technologies, Technical University of Budapest, H-1512 Budapest, Gellért tér 4., Hungary, [3] Department of Organic Chemistry, Technical University of Budapest, H-1512 Budapest, Gellért tér 4., Hungary.

There has been much interest in designing certain information into macrocyclic hosts, which enables these molecules to recognize specific guests. In this design process determination of the crystal structures of pure hosts as well as those of the host - guest complexes provides information on the chemical, steric and electrostatic interactions between the interacting counterparts and facilitates the optimization of favorable interactions which may result in improved specificity of the recognition process.

Specific recognition of chiral compounds is of particular interest due to important industrial applications. Chiral crowns have been demonstrated to be selective chiral resolving agents in many instances. Our recent study is focused on the structure determination of a (R,R)-phenazyno-18-crown-6 in its uncomplexed form as well as in its complexes with both naphtyl-ethyl-ammonium perchlorate.

Differences in stability of the two diastereomeric compounds provide explanation for the specificity of the phenazyno-18-crown-6. The three structural factors responsible for stability of the complexes are: H-bond distances between naphtyl-NH3+ and crown heteroatoms, p-p interaction between the aromatic moiety of host and guest (attractive) and steric repulsion between host and guest hydrogens (repulsive). The examinations are also supported by molecular mechanical calculations. A comparison with similar studies based on a CSD search will also be presented.

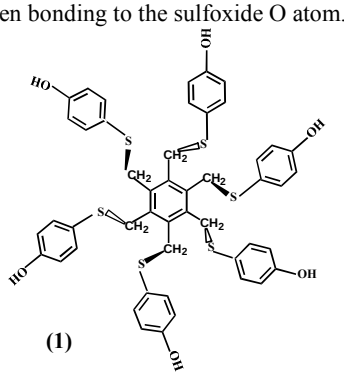
P08.06.006 INSECTS, SPIDERS, INCLUSIONS AND OTHER CURIOSITIES: *SEXI*PEDAL AND *OCTA*PEDAL HOST MOLECULES. Mátyás Czugler, David D. MacNicol and Derek R. Wilson, Chemistry Department, University of Glasgow, Glasgow G12 8QQ, Scotland

Cocrystallisation experiments of the hexahost[1] hexakis(p-hydroxyphenylthio)benzene (**1**) yielded to crystals and LT-X-ray structure determinations of the pure host **1** from *Hünigs base* and its unusual stoichiometry inclusions from 1,4-dioxane (**1a**, 1:4) and dimethylsulfoxide and water (**1b**, 1:4:2) as well. Respective guests in **1a** and **1b** are anchored through H-bonding and steric fit. The host molecule shows conformation change in its side wings orientations upon guest binding. Molecular graphics analyses revealed that host **1** conformation is changed such that on binding the host molecules assume a more open conformation. Rotations in the side wings accompany associate formation. One guest in inclusion **1a** is bound by steric fit and van der Waals interactions. In **1b** one of the DMSO guests is partly bound by the fit to the central aromatic ring of the host molecule and concurrent hydrogen bonding to the sulfoxide O atom.



An octakisthio-naphtalene host has also been done. It is substituted with camphor groups in accord with earlier studies aiming at providing chirality in the host molecule.

[1] D. D. MacNicol, D. R. Wilson, *J. Chem. Soc., Chem. Commun.* **1976**, 494-495.

P08.06.007 CALIX[4]RESORCINARENES - SELF-ASSOCIATION AND CRYSTAL PACKING. A.T. Gubaidullin, A.E.Arbuzov Institute of Organic and Physical Chemistry, Kazan Scientific Centre of the Russian Academy of Sciences, Arbuzov str., 8, Kazan 420088 Russia

There is a general trend to consider the three-dimensional crystal packing of the calix[4]arene complexes as bilayered structures. But highly solvated structures can be considered as crystals built up of molecules strongly bound by their first solvation shells. Using X-ray single crystal, X-ray powder diffraction and small-angle X-ray scattering methods we investigate the supramolecular structure of a series of new calix[4]arene derivatives and their ionic metal (Zn, Pd, Cd, Co, Ni) chloride complexes, where calixarene residues exist in neutral, protonated and deprotonated forms. It was shown that the structure of the calixarene moiety and three dimensional arrangement of the complexes depend greatly on the ”guest” metal and inclusion of solvate molecules. Conformational modifications of the macrocycles induced by the process of complexation are discussed based on the comparative analysis of these data with data obtained for neutral “host” calixarene molecules. In compounds under investigation the hydrophobic and hydrophilic regions are strongly localised in crystals. As building units of the three dimensional packing a fragmentary structure, consisting of infinite one-dimensional stick, is chosen. This stick consists of hydrophobic calixarene residues, whereas polar substituents, inorganic ions and/or solvate molecules form hydrophilic shell around the sticks. Several types of superstructures which differ by the host: guest stoichiometry and the respective disposition of guest and host molecules is observed. The factors determining the process of complex formation are discussed. The results of kinetic investigation of crystal formation from self-associates in solution to single-crystal is presented. It was shown that the solid state structure of calixarenes and complexes is reorganized upon the solvent exclusion and temperature increasing. For these complexes the formation of molecular aggregation in solution is observed, the shape and parameters of aggregates is analysed. The influence of solvent and host-guest molecules on the supramolecular structure is discussed.

P08.06.008 STRUCTURES OF A *P-TERT*-BUTYL CALIX(4)ARENE DERIVATIVE AND ITS SODIUM COMPLEX. O.E. Piro, Dept. Física, Ftad. C. Exactas, Univ. Nacional de La Plata, C.C. 67, 1900 La Plata, Argentina, N.J. Al Rawi and A.F. Danil De Namor, Lab. of Thermochemistry, Univ. of Surrey, Guildford, Surrey, UK GU2 5XH and E.E. Castellano, Inst. Física de São Carlos, Univ. de São Paulo, C.P. 369, 13560 São Carlos (SP), Brazil

Recently, we reported the synthesis, ^{1}H NMR characterization and X-ray structure of 5,11,17,23-tetra-*tert*-butyl-[25,27-bis(2-pyridylethyl)oxy-26,28-bis(methylthiodiethyl)oxy] calix(4)arene, $C_{62}H_{78}N_2O_4S_2$[1]. The hydrophobic calix bounded by the four phenyl rings has the usual distorted cone conformation exhibited by a whole variety of *p-tert*-butylcalix(4)arene derivatives. The hydrophilic cavity is defined by alternating OCH_2Py and $O(CH_2)_2SCH_3$ pendant groups. The complex with the sodium ion crystallises in the tetragonal system with *a*=15.201(4), *c*=13.376(3) Å and Z=2. Preliminary results assuming P-4 space group show the complex sited on a twofold axis and large positional disorder of the pendant groups that conform the hydrophilic cavity. The Na^+ ion is found in this cavity coordinated by the four phenolic oxygens [average d(Na-O)=2.42 Å] as in the case of the sodium complex of the related derivative where all four pendant groups are OCH_2Py[2]. The structural studies confirm the key role played by the O-CH_2-(2-pyridyl) pendant group in the ability of *p-tert*-butylcalix(4)arene derivatives to complex and transport metal cations in solution.

P08.06.009 STRUCTURAL STUDY OF DIBENZO-30-CROWN-10 COMPLEXES. Matijasic I.[1], Dapporto P.[2], Tusek-Bozic Lj.[3], [1] Laboratory of Organic Chemistry, Faculty of Science, Zagreb, Croatia, [2] Dipartimento di Energetica, Universita di Firenze, Firenze, Italy, [3] Department of Chemistry, Ruder Boskovic Institute, Zagreb, Croatia

Host-guest chemistry of macrocyclic polyethers has the considerably biological relevance as model substances of naturally occurring ionophores for the study of ion-transport processes in cell membranes and investigation of receptor-enzyme interactions.

The chemistry of metal-ion macrocyclic complexes and their crystal structures are influenced by a variety of factors, which include the size and ionic character of the cation respectively the flexibility and cavity size of the ring. All these factors must be taken into account when tailoring ligands to recognize particular metal ions. Much effort has centered on understanding the effects of altering the nature of metal or ligand on the stoichiometry and structure of the complexes formed.

In the continuation of our systematic investigation on the complexes with different crown ethers[1,2] we are focusing here on the crystal and molecular structure of potassium (**1**) and ammonium hexafluorophosphate complex (**2**) with dibenzo-30-crown-10. In both complexes the cation is completely encapsulated by this large crown molecule having a quite similar conformation.

P08.06.010 HOLES IN CRYSTALS? Mr. Peter Müller, Institut für Anorganische Chemie, Tammannstr. 4, Göttingen, Germany

In collaboration with the groups of Prof. Schlumlter (Institut für Organische Chemie, FU Berlin) and Prof. Saenger (Institut für Kristallographie,FU Berlin) we have determined the crystal structure of a cyclotetraicosaphenylene, an oligophenylene with 24 phenylene rings.[1] After some less sucessfull crystallization experiments, good looking crystals that diffract disappointingly weak but acceptably were obtained from chloroform. Highly redundant data were collected at 133 K on a rotating anode / multiwire proportional counter system up to 0.95 Å to a completeness of 99.9 %. In this context it should be emphasized that the quality of data is highly influenced by the redundancy. Although a higher redundancy tends to increase the merging R-value Rsym [2], it also improves the quality and I/sigma ratio for the averaged reflections. The structure was solved with conventional direct methods using SHELXS [3]. The packing of the cyclotetraicosaphenylene in the crystal shows large empty channels (diameter 18 Å ring;) through the whole crystal. The cocrystallized solvent molecules whose position could be determined are located outside this holes and between the *n*-hexyl chains. Presumably, the holes are filled with highly disordered and maybe even liquid chloroform.

P08.06.012 DNA BINDING STUDIES ON QUINOLONES BY SPECTROSCOPIC METHODS. L.Sudha and K.Subramanian, Department Of Physics, College Of Engineering, Anna University, Chennai 600 025, INDIA

This paper presents the evidence for the formation of the complexes between quinolones and ct-DNA. The quinolones represent a relatively new class of antibiotics with outstanding therapeutic potential, attributable to their broad spectrum of antimicrobial activity and favourable distribution. We have determined the structure of these compounds by X-ray methods.The interaction of three quinolones namely

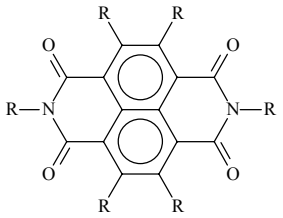
(1) 5-Amino-8-methyl-2-quinolone monohydrate[quinolone I]
(2) 5-(Dimethylamino)-8-methyl -2- quinolone[quinolone II]
(3) 5-(Isopropylamino)-8-methyl -2- quinolone[quinolone III]

to DNA are studied by spectroscopic methods.

Spectrophotometric and Spectrofluorimetric methods were employed to study the interaction with calf thymus(ct) DNA. From the results of these studies various binding prameters were evaluated. Extensive hypochromism, broadening and red shifts in the absorption and fluorescence apectra were observed when quinolones bind to ct-DNA.In absorption spectra there is a maximum red shift of 3,5 and 5nm were observed at 279, 315 and 319nm for quinolone I, II and III. Binding of the quinolone probe to the ct-DNA helix was found to quench the probe fluorescence strongly. It essentially involves a maximum red shift of 9, 6 and 6nm for quinolones I, II and III. Scatchard plots constructed from these data are used to calculate the binding constants. Stern-Volmer quenching constants were obtained from the linear quenching plots. Strong hypochroism, strong quenching of the probe fluorescence and red shifted absorption and fluorescent spectra strongly support the binding of the quinolone chromophore.

P08.06.013 CONFORMATIONAL ANALYSIS OF NAPHTHOYLENE-IMIDES-MODEL COMPOUNDS OF RIGID-CHAIN HETERO-CYCLIC POLYMERS. A.Yu. Kovalevsky, I.A. Ronova, I.I. Ponomarev, A.N. Nesmeyanov Institute of Organoelement Compounds, Russian Academy of Sciences, 28 Vavilov st., Moscow 117813, Russia, and O.V. Shishkin, SRD Alkali Halide Crystals, STC «Institute for Single Crystals», National Academy of Sciences of the Ukraine, 60 Lenin ave., Kharkov 310001, Ukraine.

Using X-ray structural analysis and calculations by semi-empirical quantum-chemical method AM1, molecular structure and conformational flexibility of series of naphthoyleneimide derivatives have been studied.



R=H, Me, Ph, *tert*-Bu, o-COOH-C_6H_4, m-OMe-C_6H_4, p-OMe-C_6H_4, p-NO_2-C_6H_4,

The six-membered partly hydrogenated imide cycle in naphthoyleneimide possesses high conformational flexibility, The transition from a planar equilibrium conformation to a sofa with the C(Ar)-C(=O)-NH-C(=O) torsion angle ±20° results in energy increase only about 2.5 kcal/mol. Equilibrium conformation of mono (Me, Ph, t-Bu), di and tetra (Me, Ph) substituted molecules is planar. But imide cycle in di and tetra t-Bu subsituted molecules has a distorted boat conformation. Steric repulsion between atoms of the substituents and adjacent carbonyl groups causes appreciable increase of conformational flexibility of imide ring. The latter grows as substituent volume enlarges in the row of Me, Ph, t-Bu.

Using Monte-Carlo method, the values of Kuhn segment of polymers contained in their structural unit naphthoyleneimide moiety have been calculated. Polymer conformational rigidity depends on the conformational flexibility of imide cycle. The calculation showed that the rigidity of polynaphthoylenimided encreases on going from unsustituted to mono, di and tetra substituted monomeric units.

P08.06.014 CRYSTAL STRUCTURE STUDIES ON FLUORINATED BENZYLIDENE ANILINES. K.V.Arjuna Gowda, M.K.Kokila, Puttaraja, Department of Physics, Jnana.Bharathi. Campus, Bangalore University, Bangalore-560 056 M.V.Kulkarni, Department of Chemistry, Karnataka University, Dharwad 580 003 and N.C.Shivaprakash, Department of Instrumentation, Indian Institute of Science, Bangalore-560 012, INDIA.

Benzylidine anilines(I) have been found to be non-planar compared to the Azobenzenes(II). Further studies on the crystal structure of (I) with substituents like-chloro,-nitro and methoxy at different positions in the rings A and B give rise to interesting solid state confirmations with the angle of twist around CN bond up to 45^0.

We have studied a variety of benzylidine anilines (I) which have 4-Fluoro 3-Chloro substitution in ring A where as ring B has 4-Chloro, 4-dimethylamino, 3,4,5-methoxy and other groups. These compounds have been studied for their densities, molecular packing and their solid state geometries. The results obtained during this investigation indicate the presence intermolecular C-H…F bonds as the forces of stabilisation. The molecules adopt E-configuration and a non-planar arrangement across CN bond.

The structures have been solved by direct methods using SHELXS-86 and refined by a full-matrix least-squares method using SHELXL-93 program.

P08.06.015 STRUCTURE AND MECHANISM OF PHOTOCHEMICAL AND PHOTOPHYSICAL TRANSFORMATION OF NEW SPIROOXAZINES AND 2R-CHROMENES. S.M.Aldoshin and I.I.Chuev, Institute for Chemical Physics Research, Russian Academy of Sciences, Chernogolovka, 142432, Moscow Region, Russia

New photochromic substituted spiro[indoline-2,3'-[3H]-naphtho[2,1-b] [1,4] oxazines (**SO**) with substituents of different types, R_1, R_2-chromenes (**CH**) (CH_3, CH_3; CH_3, Ph; Ph, Ph) and fluorenechromenes have been synthesized. Influence of their specific structural features on photochemical properties (photocolorability, kinetics of dark bleaching) has been studied by using X-ray analysis and quantum chemistry methods. The C-O bond being broken upon photoexcitation was shown to be elongated in the ground state, like in indoline spiropyrans (**SP**). Based on *ab initio* quantum-chemical calculations (3-21G basis), influence of the **SO** molecule geometry on efficiency of anomeric interaction of the lone electron pair of the nitrogen atom with antibonding orbital of the Cspiro – O bond has been studied. The decisive role of this interaction for the elongation of the Cspiro –O bond in the ground and electron-excited states has been shown.

Electron and spatial influence of substituents on the structure, photocolorability and dark bleaching of **SO** and **CH** has been studied. Correlation of photocolorability and the energy of steric strain of the pyran (oxazine) ring has been found for a series of similar **SO** and **CH**.

By purposeful modifying of the **CH** molecular structure, Ph,Ph-chromenes with phenyl rings linked by bridges of different length and nature have been synthesized and studied. Arrangement of the Ph-rings with respect to the C – O bond being broken was shown to influence essentially the photocolorability.

Using the semi-empirical quantum-chemical method (PM3 (MOPAC93)), coordinates of the reaction of cycles disclosure in the ground and the first singlet-excited state have been studied for molecules **SO**, **SP** and R_1, R_2-**CH**.

The ways for structural modification of **SO**, **SP** and **CH** to improve their photochromic properties have been formulated and realized.

P08.06.016 INFLUENCE OF HYDROGEN BONDING ON CONFORMATION OF PHOSPHORYL COMPOUNDS IN SOLUTION AND SOLID STATE. Susan A Bourne, Department of Chemistry, University of Cape Town, Rondebosch 7701, South Africa and Tomasz A Modro, Centre for Heteroatom Chemistry, Department of Chemistry, University of Pretoria, Pretoria 0002, South Africa.

In recent years we have studied a series of compounds containing the phosphoryl moiety. These have yielded interesting correlations between their reactivity and structural features. Of particular interest is the connection between the hydrogen bonding (which often persists in solution) and reactivity.

Compounds **1** and **2** form strong intermolecular hydrogen bonds between N-H and P=O groups of adjacent molecules in the crystalline state. The intramolecular O-P-N-H torsion angle is close to zero in **2** and *ca.* 120° in **1**. These conformations have also been shown to exist in solution and have a profound impact on the use of these compounds as hydrogen bonding reagents in resolution crystallisation.

Compound **3** displays weak (sp^3)C-H...O=P hydrogen bonding that is strong enough to persist even in polar organic solvents. This type of interaction may have relevance to the

structure and reactivity of biomolecules containing organophosphorus functions.

P08.06.018 LOCAL ARRANGEMENTS OF ESTER LINKAGES IN CRYSTALS. K. Hori and N. Seo Graduate School of Humanities and Sciences, Ochanomizu University, Bunkyo-ku, Tokyo 112-8610, Japan

Biphenyl ester is a typical mesogenic unit, which produces various mesophases according to the substituents. Relationships between molecular structures and packing modes of molecules are essential to understand the mesophase behavior. We have carried out systematic crystal structure analysis for biphenyl esters with the general formura, R1-C6H4-C6H4-COO-C6H4-R2. Two types of local arrangements of ester linkages were found for compounds, where R1 or R2 is chiral [1]. For componds with chiral R1, an antiparallel arrangement of ester linkages is found, while for those with normal alkoxy chain as R1, a closely arranged ester and ether linkages of the alkoxy chain is found. The latter mode has been found also in many antiferroelectric mesogens. Crystal structure analysis has been extended to biphenyl esters with normal alkyl and/or alkoxy chains for both R1 and R2. Different arrangements of ester linkages are observed in these crystals. They are two kinds of one-dimensional chains of close arrangements of ester linkages; C=O...C=O...C=O with O...C distances of 3.2-3.6 A and O-C=O...O-C=O with rather long O...O distances of 3.8-3.9 A. The former is found mainly for compounds with a normal alkoxy chain as R1. The latter is found for those with a normal alkyl chain as R1, regardless of the type of R2 (chiral or normal).

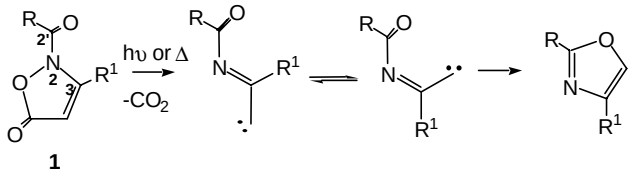
P08.06.019 MOLECULAR MODELLING, CRYSTAL AND MOLECULAR STRUCTURES OF SOME N-ACYLISOXAZOL-5(2H)-ONES. Max R. Taylor, Mei Fong, Rolf H. Prager and Kia S. Wallwork, Chemistry Department, The Flinders University of South Australia, GPO Box 2100, Adelaide, Australia 5001.

We have reported that N-acylisoxazol-5(2H)-ones, **1**, undergo loss of CO_2 when irradiated at 300 nm, or when subjected to flash vacuum pyrolysis, to give oxazoles[1] (Scheme 1). Theoretical calculations suggest a number of steps are involved in attaining the ideal geometry for cyclisation of the carbene intermediate. In an attempt to predict the reactivity of variously substituted isoxazolones we have carried out *ab initio* calculations at the RHF/16-31G* level of theory to predict the geometry of C3-N2-C2'-O in **1** substituted with groups with varying electronic and steric characteristics, and have confirmed the usefulness of this approach by single crystal X-ray structure elucidation. Considerable deviations from planarity, both at the N and CO group were predicted and confirmed.



1

Scheme 1

The crystal and molecular structures of five different substituted isoxazolones will be presented and inferences drawn between the computational and experimental evidence. Relationships between conformations found in the crystalline environment, the gas phase and reactivity will be explored.

P08.06.020 CRYSTAL STRUCTURES OF 6-CHLORO-4-HYDRAZINE-2-PHENYL-3-PYRIDAZINONE. Anna Katrusiak and S. Baloniak [1], Andrzej Katrusiak [2], [1] Department of Organic Chemistry, School of Medicine, Grunwaldzka 6, 60-780 Poznan, [2] Department of Crystal Chemistry, Adam Mickiewicz University, Grunwaldzka 6, 60-780 Poznan, Poland

The molecules of 6-chloro-4-(N,N-dimethyl-aminemethylidenohydrazine)-2- phenyl-3(2H)-pyridazinone are hydrogen-bonded by a pair of N(3)H--O= bonds into centrosymmetric dimers. The crystal structures of this compound and of its inclusion compound with water were determined by X-rays [1]. Presently we report the N(3)-methyl derivative of this compound, where the H-donor is blocked and no hydrogen bonds can be formed. We were mainly interested in the modifications of the pharmaceutical activity of this substance, in the changes of its solubility, stability and other physical and chemical characteristics, however we have also investigated by X-ray diffraction the changes induced into the molecular conformation by the methyl substitute, and also in the changes in the intermolecular interactions of the molecules in the crystal structure. In order to elucidate the binding sites of these molecules in living tissues, a quantitative analysis of the changes in their molecular aggregation will be presented.

1. A. Katrusiak and A. Katrusiak, J. Mol. Struct. 374 (1996) 251.

P08.06.021 CRYSTAL STRUCTURE OF A MESOGENIC COMPOUND : P-BUTOXYPHENYL TRANS-4-PROPYL CYCLOHEXANE CARBOXYLATE. S. Ghosh, S. K. Giri, P. K. Mandal, S. Paul [1], T. Manisekaran [2], [1] Department of Physics, University of North Bengal, Siliguri, Darjeeling-734 430, W.B., India, [2] Indian Institute of Technology, Chennai-600 036, India

The studies of the physical properties like the density, refractive index, magnetic susceptibility anisotropy, bend & splay elastic constants and also the X-ray diffraction on p-butoxyphenyl trans-4-propyl cyclohexane carboxylate (BPPCC in short) in its mesophases are carried out by N. K. Pradhan et al.[1]. The molecular arrangement in the crystalline structure is one of the factors which in most cases predetermines the occurrence of thermal mesomorphism in organic compounds and in this context we have undertaken the crystal structure determination. The crystal and molecular structure of the above compound is solved by direct method. The crystal belongs to the monoclinic system with space group P21/a, a =11.2483, b=20.2968, c=17.6311, beta = 100.3425 and eight molecules per unit cell. The structure refined to an R value of 0.07 by full matrix least squares for 5434 observed reflections. Some of the bond-length and temperature parameter values are found to be very large. It means the structure

is highly disordered. Acknowledgement : S. Ghosh and S. K. Giri are thankful to DST, India for providing Research Fellowships. The authors would like to acknowledge Prof. R. Dabrowski for kindly donating the sample used in this work.

[1] N. K. Pradhan, PhD Thesis submitted to University of North Bengal (1998).

P08.06.022 MOLECULAR STRUCTURE OF 2-(4'-*N,N*-DIETHYL-AMINOPHENYLAZO)PYRIDINE. Kanidtha Hansongnern and S. Onganusorn, Department of Chemistry, Faculty of Science, Prince of Songkla University, Hat-Yai, Songkla 90112; Kenneth J. Haller, School of Chemistry, Suranaree University of Technology, Nakhon Ratchasima 30000, Thailand.

The red colored title compound was synthesized and the structure characterized. It is a derivative of 2-(phenylazo)pyridine (azpy) which acts as an excellent ligand to stabilize ruthenium(II) in complexes (S. Goswami, A.R. Chakravarty, A. Chakravorty, *Inorg. Chem.* 22 (1983) 602-9). Its use as a potential ligand to ruthenium is currently under investigation.

The structure shows the phenyl and pyridine rings to be trans and essentially coplanar with the azo linkage; the C5-N2-N3-C6 torsional angle is -179.2 (2)º and the azo bond length, N2=N3, is 1.215 (3) Å. The angle between the planes of the phenyl and pyridine rings is 2.5 (2)º, largely due to rotation relative to the long axis of the molecule.

Bonding in the linkage between the phenyl and pyridine is altered compared to complexes containing azpy as ligands. The azo distance is significantly shorter than that in complexes, *eg.* Ru(azpy)$(N_3)_2$, N=N = 1.289(9) & 1.291(9) Å, (K. Krause, R.A. Krause, S. Larsen, B. Rasmussen, *Acta Chem. Scand.* A39 (1985) 375-88); and the azo-phenyl distance is significantly longer, C-N = 1.371(10) & 1.370(10) Å, compared to N2-C5 = 1.487(3) Å in the title compound, while the azo N=N-phenyl C angle, C-N-N = 111.8(6) & 112.1(6), in the complex, is nearly tetrahedral, C5-N2-N3 = 109.2(2), in the title compound.

Recrystallized from ethanol solution as thick red plate crystals. *Crystal Data:* $C_{15}H_{18}N_4$, *MW*=254.34, *MP*=105-6 ºC, orthorhombic $P2_12_12_1$ (No. 19), *a*=7.483 (1), *b*=9.096 (1), *c*=21.019 (3) Å, *V*=1430.7 (4) Å^3, *T*=297±2 K, *z*=4, d_{calc}=1.181 Mg m^{-3}, μ=0.073 mm^{-1}, MoKα radiation, *F(000)*=544., $sin\theta/\lambda_{max}$=0.615 Å^{-1}, R_{int}=0.043, 2738 unique data, 1788 $F_o>4\sigma(F_o)$, R_1=0.043, wR_2=0.115, gof=1.01.

P08.06.023 MOLECULAR STRUCTURE OF THE ZWITTERIONIC 4-HYDROXY-*N*-METHYL-L-PROLINE. Kenneth J. Haller, School of Chemistry, Suranaree University of Technology, Nakhon Ratchasima 30000, Amorn Petsom, Sophon Roengsumran, Dep Shiengthong, Weeraya Lertwanitch, Prapapan Techasauvapak, Waraporn Rungruangkanokkul, Department of Chemistry, Faculty of Science, Chulalongkorn University, Bangkok, 10330, Thailand

The title compound was isolated from the ground dried flowers of *Aglaia odorata* Lour, and identified by its physical and chemical properties (Shiengthong, Lertwanitch, Techasauvapak, Rungruangkanokkul, Roengsumran, Petsom, Haller, *18th Congress on Science and Technology in Thailand*, (1992) Abstract A-52); representing the first report of the compound in *Aglaia* species.

The carboxylic acid proton has transferred to the nitrogen atom giving a zwitterion in the solid state. The C-N distances are unremarkable, C_α-N=1.494(2), C_δ-N=1.504(2), and C_{Me}-N=1.486(2) Å. The anionic carboxylate exhibits essentially equal C-O bonds, 1.244(2) and 1.249(2) Å and a somewhat opened O-C-O angle, 127.4(2)º as normal. The remaining ring distances are: C_α-C_β=1.524(3), C_β-C_γ=1.524(3), C_γ-C_δ=1.533(2), Å, and the distances for the carboxylate carbon-Cα and the hydroxy O-Cγ bonds are 1.529(2) and 1.417(2) respectively.

Recrystallized from methanol solution as large clear colorless rod shaped crystals. *Crystal Data:* $C_6H_{11}NO_3$, *MW*=145.16, *MP*=236-38 ºC, monoclinic $P2_1$ (No. 4), *a*=6.7396 (6), *b*=5.8417 (8), *c*=8.8800 (9) Å, β=100.836 (6)º, *V*=343.38 (8) Å^3, *T*=297±2 K, *z*=2, d_{calc}=1.404 Mg m^{-3}, μ=0.011 mm^{-1}, MoKα radiation, *F(000)*=156., $sin\theta/\lambda_{max}$=0.595 Å^{-1}, R_{int}=0.0102 (from 215 pairs), 1007 unique data, 792 $F_o>4\sigma(F_o)$, R_1=0.0258, wR_2=0.0727, gof=1.113.

P09.06.001 A VOLUMETRIC MEASURE OF ISO-STRUCTURALITY. László Fábián and Alajos Kálmán, Institute of Chemistry, Chemical Research Center, Hungarian Academy of Sciences, P.O.Box 17, H-1525 Budapest, Hungary.

The study of isostructurality is a useful tool in the understanding of related crystal structures. A detailed analysis requires numerical descriptors as well. However, the application of the isostructurality index introduced by Kálmán *et al.* [1] is limited to cases where a straightforward atom-atom correspondence can be established between the structures under investigation.

Hence a new measure of isostructurality based on the overlap of molecular volumes is suggested:

$$I_v = \frac{2V_\cap}{V_1 + V_2} 100\%$$

where $V_\cap$ is the overlap of the two molecular volumes V_1 and V_2. A numerical algorithm has been developed for the calculation of I_v and the method has been extended to treat disordered structures as well.

The results of I_v calculations on selected literature examples will be presented. They provide additional insight into the close packing of both homomolecular crystals and inclusion compounds. The examples illustrate the tolerance of crystal structures to molecular alternations, the stiffness or looseness of different structural units and the relative strength of host-guest interactions.

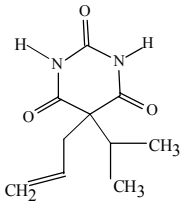
P09.06.002 SOLID STATE INVESTIGATION ON THE POLYMORPHIC SYSTEM OF APROBARBITAL- 5-ALLYL-5-ISOPROPYLBARBITURIC ACID Navon O.[1.], Bernstein J.[1] [1.]Department of Chemistry, Ben-Gurion University of the Negev, Beer Sheva 84105 Israel.

Barbiturates are a class of drugs which exhibit widespread polymorphism. Barbiturates have diverse actions in biological systems. In addition to their widely known sedative effects, they are also regarded as general metabolic depressants because they inhibit a large number of enzyme systems. They have well defined hydrogen bonding networks. In the course of investigating of a number of molecules in this family we worked on the molecule 5-ally - 5-isopropylbarbituric acid.



There is only one known structure in the Cambridge Crystallographic Database [1], although Kuhnert - Brandstätter [2] reported the existence of six polymorphs. We can report here of three new forms. We will present the solid state characterization

of the different forms, using: single crystal X-ray structure analysis, X-ray powder diffraction, solid state NMR thermal analysis, graph set analysis, and lattice energy calculations, in an effort to understand and to control the structure and polymorphic form.

P09.06.003 PHASE TRANSITIONS IN $H_2T(4\text{-}OC_{12}H_{25})PP$ BY SINGLE-CRYSTAL X-RAY DIFFRACTOMETRY. J. Slowikowska[a], G.L. Perlovich[b], J. Lipkowski[a], W. Zielenkiewicz[a]; [a]Institute of Physical Chemistry, Polish Academy of Sciences, ul. Kasprzaka 44/52, 01-224 Warsaw, Poland; [b]Institute of Solution Chemistry, Russian Academy of Sciences, Academicheskaya Str., Ivanovo, 153045, Russia.

Polymorphism and phase transitions are the two phenomena which have gained an increasing attention in the recent years as crucial in such key areas of chemistry as pharmaceutical industry and rapidly developing crystal engineering. Various applications of porphyrin derivatives, starting from anti-cancer agents to building blocks in design of programmed crystal architectures, place this class of compounds at the intersection of these two domains making them particularly interesting for thorough studies of their structural changes.

The phase behaviour of $H_2T(4\text{-}OC_{12}H_{25})PP$ porphyrin (**1**) has been investigated by single-crystal X-ray diffraction at temperatures ranging from 100K to 362K. The changes in the unit cell dimensions, volume and intensities of individual reflections were monitored, giving a total of 15 unit cell determinations. At least six discrete reversible phase transitions were observed within 240-355K by DSC measurements. It is worth to note that the single crystal is preserved during all these phase transformations. Intensity data collection were done at 120K, 295K, 345K, and 362K. The structure is well ordered at 120K, but at room temperature only the central part of the molecule could be localised. At higher temperatures poor intensity data do not allow a complete structural analysis. However, interesting structural behaviour was observed in the form of superstructure (in a very narrow temperature range at about 350K) resulting in a doubling of the unit cell *a* constant and a decrease in β angle. It is concluded that the phase transformations in **1** are ascribed mostly to order-disorder type transitions in long alkyl chains of the phenyl rings.

Crystal data for **1** at 120K: ($P2_1/c$, a = 19.432(3)Å, b = 19.213(3)Å, c = 10.552(2)Å, β = 93.71(1)º).

P09.06.004 $Ba_2Cu(HCOO)_6$, THERMAL BEHAVIOR AND CRYSTAL STRUCTURE OF THE ROOM TEMPERATURE PHASE. P.K. de Perazzo, D. Vega, G. Polla, A.G. Leyva, H. Lanza, , R. Baggio, M.A.R. de Benyacar, .U. A. Fisica, CNEA, Avda del Libertador 8250, 1429 Cap. Fed., Argentina, J. Ellena, Depto de Fisica, Facultad de Ciencias Exactas, Universidad Nacional de La Plata, La Plata, Argentina, and H.Tolentino and M do Carmo Martins Alves, Laboratorio Nacional Luz Sincrotron, Campinas, San Pablo, Brasil.

$Ba_2Cu(HCOO)_6$ grown at room temperature crystallises in space group $P2_1$; a = 11.092 Å, b = 7.079 Å, c = 17.391 Å, β = 91.64^0; V = 1365 Å^3, Z = 4, D_c = 2.96gr/cm^3. On heating the following changes are observed : 1) a reversible, hysteretic, first order phase transition at about 60-90^o C; 2) partial decomposition at 190^o C and 3) an irreversible change at 230^o C related to decomposition. We have assigned to a new γ-$Ba(HCOO)_2$ metastable phase one of the main components found in $Ba_2Cu(HCOO)_6$ samples quenched from 190^o C.

A room temperature model structure of $Ba_2Cu(HCOO)_6$ is given. The copper atoms are surrounded by 7 oxygen atoms: 5 of them defining an almost perfect square pyramid, and the remaining two, opposite to the apex, at hemicoordination distances of ca. 2.85Å. Even though the two nearest neighbours contributions accounted fairly well for many of the details of the EXAFS absorption curve, only the inclusion of the oxygens at 2.85 Å made the match nearly perfect.

The barium atoms display irregular, ninefold coordination polyhedra arranged as corrugated planes which share two faces with the copper coordination polyhedra. This crystal structure is different from those reported for the copper-dicalcium and the copper-strontium anhydrous double formates.

P09.06.005 MOLECULAR PACKING AND POLYMORPHISM IN INORGANIC FLUORIDES. Arkady Ellern. Ben-Gurion University of the Negev, Chemistry Department, P.O.B. 653, Beer-Sheva, Israel.*

If the substance in solid state forms molecular crystals, two reasons for a polymorphism can be found in principle. The first one is the different molecular structure of the molecule. In this case the origin blocks for a building of the crystal (the molecule) in different polymorphs are chemically equivalent, but have different geometrical parameters. The majority of the cases of the polymorphism in organic chemistry belong to this type, because the organic molecule can be rather flexible. Even a small change of the conformations of substituent (as Et, Bu etc) can be responsible for the crystallization in different crystal packing mode. The second type of polymorphism includes the cases when the molecules have absolutely the same geometrical parameters in both modifications and the reason for polymorphism is a different kind of intermolecular interaction or a small distortion of the crystal lattice.

The molecular structure can be qualitatively predicted for most of the binary fluorides, because usually they can adopt the only molecular geometry. The obtained phase diagram of the system BrF_3-BF_3 shows the existence of polymorphism of the second type even for such simple fluorides as BF_3 and ClF_3. The results of precise low-temperature X-ray analysis of all compounds in this system will be presented in this contribution.

The X-ray data for the variety of the derivatives of halogen fluorides and xenon fluorides show that the surprising packing mode of ClF is not the only exception from the “F-bridging” model, which is typical for inorganic fluorides.

The work was supported in part by Alexander von Humboldt Foundation.

P09.06.006 AN IN-DEPTH STUDY OF GROWTH SPIRALS ON CdI_2 CRYSTALS IN RELATION TO THE FORMATION OF POLYTYPES. Rajendra Singh and G.C. Trigunayat, Department of Physics and Astrophysics, University of Delhi, Delhi-110007, India and S.B. Samanta and A.V. Narlikar, National Physical Laboratory, K.S. Krishnan Marg, New Delhi-110012, India.

A collective sequential study of growth spirals on the basal surfaces of the richly polytypic cadmium iodide crystals has been carried out by optical microscopy, scanning electron microscopy and scanning tunneling microscopy, which has yielded some novel results. The STM enables an unambiguous and accurate measurement of the step heights. When the large height growth steps viewed through optical microscopy are further examined by SEM, a large number of additional steps of smaller height are discovered to exist between any two originally seen adjacent growth steps. When next viewed through STM, which provides still higher resolution of images, numerous unit substeps are found to exist between two consecutive additional steps. The height of each substep equals the unit cell height of the underlying

polytype (hence termed as "unit" substep) and the height of the larger aforesaid additional step is found to be an integral multiple of the unit cell height. The results have important bearing on understanding the creation of polytypes. Besides, the spacing between two successive growth steps turns out to be an integral multiple of the lattice parameter a. The interspacing of the growth steps of same step height is found to vary at different positions on the same crystal face. Additionally, the STM pictures clearly reveal the value of unit cell a (=b) dimension to be equal to 0.428 nm and the value of the interaxial angle γ to be equal to 120°, in exact conformity with the known structural data.

P09.06.007 POLYMORPHS OF DIMETHYLSULFIDE-DINITRATOPALLADIUM (II). M. Johansson and A. Oskarsson, Inorganic Chemistry 1, Chemical Centre, University of Lund, P.O. Box 124, S-221 00 Lund, Sweden.

There exists at least two polymorphs, denoted A and B, of the title compound. Both crystallize in the monoclinic space group $P2_1/n$, but with Z=4 and 8 for A and B, respectively.

Polymorph A was found in a batch prepared from $Pd(OAc)_2$ + dms + HNO_3 while B was in a batch prepared from $PdCl_2(dms)_2$ + aq + $AgNO_3$. It is reasonable to assume that both polymorps are present in both batches and this point is under investigation.

The volume per complex is 305.2(1) and 298.4(1) A^3 at room temperature while at 150 K the corresponding values are 289.3(1) and 288.8(1) A^3. Thus there is a significant difference in packing efficiency at room temperature but not at 150 K.

The donor atoms in polymorph A are disordered both at room temperature and at 150 K, while for polymorph B the donor atoms of one of the complexes are disordered at room temperature but not at 150 K. However, different crystals were used at room temperature and at 150 K and the disorder of different crystal individuals may be different.

The following aspects will be discussed on the poster

Do the synthetic procedure have effects on the relative amounts of the polymorps formed?

Is it possible to observe a temperature dependent phase transformation by studying the structures at different temperatures.

The packing in the different polymorphs will be discussed as well as the influence of intermolecular forces on intramolecular bond distances, bond angles and torsion angles.

P09.06.008 THERMALLY INDUCED TRANSFORMATIONS IN META-NITROANILINE CRYSTAL. G.Wójcik, J.Holband, M. M. Szostak, Institute of Physical and Theoretical Chemistry, Wroclaw University of Technology, Wyb. Wyspiañskiego 27, 50-370 Wroclaw, Poland.

Molecular packing changes in m-nitroaniline crystal on heating above room temperature were observed by direct dilatometry and near IR spectroscopy, suggesting possibility of a second order phase transition at 330 K [1]. Dielectric relaxation studies evidenced increasing molecular dynamics coupled with growing electric conductivity from above room temperature. An anomaly on the real part of permittivity dependence on temperature occured at 365 K. It was depicted in terms of a rotative phase - plastic phase transition. Also calorimetry (DSC) revealed a very weak anomaly at about 365 K and, additionnally, a glassy-type transition at about 160 K [2]. Structural investigations on a 4-circle automatic KUMA diffractometer with a CCD detector, equipped with an Oxford Cryosystem Unit were performed in a wide range of temperatures with the aim to verify the occurence of the transitions and to find m-nitroaniline crystal structures above the high temperature transition point and below the low-temperature one. Thermal expansion was measured in several crystallographic directions. Molecular dynamics was monitored by the evolution of mean square atomic displacements on temperature. The low temperature transition is depicted in terms of reorientations of supra-molecular strands. The role of weak hydrogen bondings is discussed.

P09.06.010 ANALYSIS OF PROBABILITY OF FORMATION OF INTRAMOLECULAR HYDROGEN-BONDED RINGS. C. Bilton, J.A.K. Howard, Department of Chemistry, University of Durham, Durham, UK. F.H. Allen, G.P.Shields, W.D.S. Motherwell. Cambridge Crystallographic Data Centre, Cambridge, UK.

Using a modified version (1) of the Cambridge Structural Database (CSD) (2) software, the April 1998 release of the database was used to analyse the probability of formation of intramolecular hydrogen-bonded rings. All intramolecular ring motifs containing between 4 and 10 atoms, formed via O-H --- O, O-H --- N, N-H --- O or N-H --- N hydrogen bonds in organic structures were recorded. The motifs were then ranked in order of their probability of formation .The results were then taken and investigated in further detail. The effect of formation of the ring on the localised geometry of the molecule and also on the potential for both the donor and acceptor to form additional hydrogen bonds will be discussed.

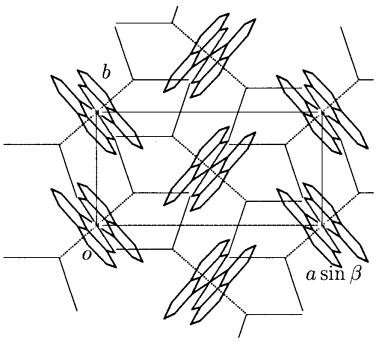
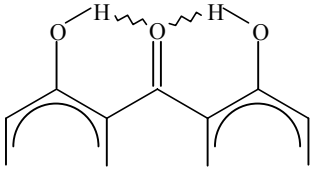
P09.06.011 DEHYDRATION PROCESS OF COPPER OXINATE DIHYDRATE - GENERATION OF TWINNING. T. Nemoto, S. Terada, S.Isoda and T. Kobayashi, Institute for Chemical Research, Kyoto University, Uji, Kyoto 611-0011, Japan.



The copper oxinate complex crystal has various polymorphs depending on its formation process [1]. One of the polymorphs, β-form, undergoes dehydration at high temperature in air or under vacuum. This dehydration process was analyzed by X-ray and electron diffraction.

The β-form crystal was obtained from aqueous acetic acid solution of copper oxinate dihydrate. It is a hexagonal plate-like crystal and belongs to the space group $P2_1/a$, Z=2 The structure determined from X-ray diffraction intensities is almost the same as that of zinc oxinate dihydrate. This result consists with that reported previously from the consideration on cell dimensions[2].



Hydrogen bond network in β-form

The two dimensional hydrogen bond network layer exists perpendicular to the c axis, and the crystal grows along this layer.

After dehydration under vacuum in TEM, the, electron diffraction photograph shows twinning[1].

The angle between the *b1** and *b2** axes of the two twin domains was 30°. The direction of c axis is common before and after dehydration. Such angle is explained from the crystal structure of the β -form.

P09.06.012 CRYSTAL STRUCTURE OF A NOVEL DIMESOGEN. J. Shashidhara Prasad and M.A Sridhar, Department of Studies in Physics, University of Mysore, Mysore 570006, INDIA and V. Surendranath, Department of Physics, Kent State University, Kent OH 44242, USA.

The title compound, 4-(cholestroxycarbonyl)pentyloxy-4′-heptyloxycarbonylbiphenyl ($C_{53}H_{78}O_5$), is a novel dimesogen which comprises of two mesogenic units dissimilar in nature. It crystallizes in the orthorhombic space group $P2_12_12_1$ with the cell parameters a = 6.241(3)Å, b = 17.943(5)Å, c = 43.13(5)Å, Z = 4. The structure was solved using SHELXS [1] and refined using SHELXL [1]. The final residual was R = 0.0803 for 1769 reflections with $I > 2\sigma(I)$. The molecule is linear and the terminal groups show stretching with higher bond distances. The packing of the molecules shows imbrication, herringbone and stacking along the *a*, *b* and *c* axes respectively. The structure also exhbits an intermolecular hydrogen bond of the type CH…O. The structure indicates the requirement to exhibit incommensurate smectic phase.

P09.06.013 STATISTICAL ASPECTS OF THE OCCURRENCE OF CRYSTAL FORMS AMONG ORGANIC DRUG SUBSTANCES. U. J. Griesser and A. Burger, Institute of Pharmacognosy, University of Innsbruck, Innrain 52, 6020 Innsbruck, Austria.

The occurrence of polymorphic modifications, hydrates and solvates with organic solvents of more than 550, chemically well defined organic drug compounds (European Pharmacopoeia 97) has been examined. This set of substances represents a random selection of generally well characterized compounds from a variety of chemical classes, which makes this set particularly attractive for a statistical analysis.

More than 55% of these substances are known to exist in more than one crystal form, 35% form polymorphic modifications, 30% hydrates and 10% solvates. These numbers represent the accessible, present knowledge but are certainly too low. However, neither the Cambridge Structural Database, nor the Beilstein database or the Merck Index provide comparable information. Here we roughly estimated 20%, 1% and 7% respectively for entries with hints to polymorphism or solvate/hydrate formation.

Generally, the different crystal species can be found in all compound classes but certain accumulations can be established. So, non-salts with low relative molecular masses (< 350) show the highest tendency to form polymorphs (> 50%). On the other hand, this group reveals the lowest amount of hydrate forming compounds (< 20%). Salt formation doubtless favors the hydrate formation but decreases the tendency to form solvates with organic solvents – besides, both the occurrence of hydrates and solvates increases with increasing size of the molecules. Thus, the highest amount of solvates (> 20%) can be recognized among non-salts with molecular masses greater than 350.

The analysis also reveals that particularly badly soluble compounds tend to occur in different polymorphic forms or as solvates. This result, as well as the fact that the occurrence of these phenomena among compounds with known bioavailability problems is above the average, indicates the importance to know and characterize any crystal form of drug substances.

P09.06.014 STRUCTURE OF α-FORM QUINACRIDONE BY ELECTRON CRYSTALLOGRAPHY. T.Ogawa, C.Furukawa, S.Moriguchi,T.Nemoto, S.Isoda and T.Kobayashi, Institute for Chemical Research, Kyoto University, Uji, Kyoto 611-0011, Japan.

For linear *trans*-quinacridone, only the structure of γ-form has been reported, even though it shows many polymorphs like α, β, γ, δ and γ'. Recently the α-form has been tried to be analysed by Lincke *et al.* [1]. They have proposed the structure from the analogical consideration on the known γ-form structure. In the present study, we tried to analyse the α-form of the quinacridone by electron crystallography with imaging plate.

The purified sample was vacuum-deposited on alkali-halide single crystalline substrate (KCl, KBr, KI or NaCl). The epitaxial orientations were different depending on the substrate used, but the electron diffraction patterns could be assigned to be the same α-form from comparison with the reported lattice spacings [2] for all substrates. By tilting the specimen films in a TEM, three-dimensional reciprocal lattice dimensions were examined. As a result, we obtained monoclinic unit cell of a=1.45nm, b=0.42nm, c=0.637nm and β=103° with Z=1, which means the density is about 1.38g/cm^3. These lattice dimensions are different from those by Linke *et al*.

In order to determine the molecular packing, the a*c*-net pattern from the epitaxial film is recorded on an imaging plate to measure the diffraction intensities as reported previously [3]. From a Patterson map and a high resolution image, rough estimation of molecular packing was firstly done, and detailed packing was determined so as for the orientation of molecule to fit the measured intensities. In the analysed structure, a quinacridone exhibits hydrogen bonding with the neighbouring molecule.

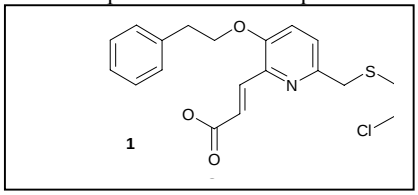
P09.06.015 POLYMORPHISM AND ITS EFFECTS ON THE SOLID STATE PHOTODIMERIZATION OF A LTB4 ANTAGONIST DRUG CANDIDATE. R. Curtis Haltiwanger*, Robert A. Daines+ and Drake S. Eggleston*, Departments of Physical and Structural Chemistry* and Medicinal Chemistry+, SmithKline Beecham Pharmaceuticals, P.O. Box 1569, King of Prussia, Pennsylvania 19406, USA.

(E)-3-[6-[[(2,6-Dichlorophenyl)thio]methyl]-3-(2-phenylethoxy)-2-pyridinyl]-2-propenoic acid, **1**, is a Leukotriene B_4 receptor antagonist representative of a class of drug molecules with the potential to treat psoriasis and other inflammatory diseases. Since exposure to sunlight is an accepted psoriasis treatment, the light-stability of this compound is of considerable interest.



There are two known Polymorphs of **1**. Form I, in the solid state, degrades nearly completely to a cyclobutane dimer after 4 hours of exposure to xenon light. Under the same conditions Form II shows approximately 4% degradation to polymeric products with no evidence of the cycloadditon product. The crystal structures of Forms I and II and of the Form I degradation product provide a clear explanation for the differences in stability between the two forms. In the crystal lattice of Form I the acrylate double bonds in adjacent molecules are nicely aligned to facilitate the light

catalyzed cycloaddition reaction. In Form 2 these double bonds are well separated and cycloaddition is not favored.

Form I - aligned double bonds

P09.06.016 THE ROLE OF H-BONDS IN THE ANISOTROPY OF STRUCTURAL DISTORTION OF PARACETAMOL AT HIGH PRESSURE. T.P. Shakhtshneider and E.V. Boldyreva, Institute of Solid State Chemistry and Mechanochemistry SB RAS, Kutateladze, 18, Novosibirsk, 128, 630128 Russia, email elena@solid.nsk.su, and H. Ahsbahs, Institute of Mineralogy of Marburg University, Hans-Meerwein Strasse, 35043 Germany.

The anisotropy of structural distortion of paracetamol (p-hydroxy-acetanilide) at hydrostatic pressures up to 4.0 GPa was followed by single-crystal X-ray diffraction in the diamond anvil cell. The crystal structure was refined anisotropically to R=0.02-0.03 at 1.0 GPa, 2.0 GPa, 3.0 GPa, 4.0 GPa. The changes in the intra- and intermolecular distances and angles were followed. The compressibility of NH...O and OH...O hydrogen bonds was measured. The role of these hydrogen bonds in the anisotropy of pressure-induced structural distortion is discussed. The diffraction data are correlated with the results of high-pressure IR-spectroscopy.

P09.06.017 NEW MEMBERS IN THE FAMILY OF NON-CLASSICAL HETEROPHANES. C. Alvarez-Rúa and S. García-Granda, Departamento de Química Física y Analítica, Universidad de Oviedo, Spain, and E. Alcalde, L. Pérez-García and N. Mesquida, Facultad de Farmacia, Universidad de Barcelona, Spain.

A great variety of molecular architectures can be found among the macrocyclic systems. Cyclophanes, phanes and heterophanes can be synthesised from different types of building blocks, which determine the physical and structural characteristics of the macrocyclic compounds. The ring components present in heterophanes are normally uncharged heteroatomic moieties, and, in the few cases in which they bear a charge, this is normally negative.

The crystal structures of some dicationic [1_4] heterophanes have been studied [1]. This kind of compounds exhibit the ability of forming specific complexes with some anions via non-covalent interactions. Crystals of these compounds are quite unstable, since a complex network of hydrogen bonding interactions appears within the crystalline lattice.

Progress in the study of the conformational analysis and non-covalent interactions of these heterophanes will be discussed.

P09.06.018 UNUSUAL C-H…π HYDROGEN BONDING. C.K.Broder, M.G.Davidson, J.A.K.Howard, University of Durham, Durham, DH1 3LE.

It has been firmly established through structural, structure correlation, and theoretical studies[1] that attractive C-H…X interactions can play a decisive role in the supramolecular structure of solids in much the same way as the stronger O-H…X and N-H…X hydrogen bonds.

We have been studying a series of novel double C-H…π bonded systems where a guest C-H donor sits in the cleft of a bis-phenol LH_2 or L^{2-} molecule. Previously, such non-classical hydrogen bonds have been seen to aid the formation of related host-guest complexes[2,3].

The compounds studied in detail here are the adduct of triphenylmethylphosphonium and L^{2-}, and the adduct of 1,3-dimethyl-2-imidazolidinone (DMI) and LH_2.

Both compounds have been studied using x-ray and neutron diffraction and the results will be discussed here.

P09.06.019 RACEMIC COMPOUND FORMATION VS. CONGLOMERATE FORMATION AMONG THE ACIDIC SALTS OF α-PHENYLETHYLAMINE WITH ACHIRAL DICARBOXYLIC ACIDS. D. Kozma[1], Z. Kovári[2], Z. Böcskei[2] and E. Fogassy[1]. [1]Department of Organic Chemical Technology, Technical University of Budapest, [2]Department of Theoretical Chemistry, Eötvös University of Budapest, Hungary

The crystal structures of a number of acidic salts of achiral dicarboxylic acids with α-phenylethylamine were investigated in order to find structural grounds for the conglomerate forming ability. Out of the eight examined dicarboxylic acids only two formed conglomerates (ithaconic and succinic acids)[1]. The others (malonic, maleinic, fumaric, glutaric, adipic and phtalic acids) form molecular compounds. We attempted the crystallization of all 14 possible racemic and optically pure salts, but succeeded only in five cases. It was found that conglomerate formation takes place when the protonated and deprotonated carboxylic groups form hydrogen bonded chains rather than cyclic intramolecular hydrogen bonds. Two of the racemate forming structures (ortho-phatlic and malonic acid salts) have the protonated dicarboxylic acids with intramolecular hydrogenbonds. In these structures the donors and acceptors are prealigned for these interactions to occur. In the P1 structure containing the optically pure form of the racemate forming adipic acid salt two crystallographycally

independent "ion pairs" are found. Interestingly in one of them the adipic acid has both of its carboxylates in the protonated form, while the other moiety is a totally deprotonated adipic acid.

All of the structures are donor deficient and therefore all donor hydrogens are involved in hydrogen bonds. A detailed qualitative and quantitative analysis of the hydrogen bond interactions and a correlation with the conglomerate forming ability will be presented.

P09.06.020 UNDERSTANDING NITROANILINES USING NEUTRON DIFFRACTION. A.E. Goeta and J.A.K. Howard, Chemistry Department, Durham University, Durham DH1 3LE, UK, J. Ellena, Instituto de Física de Saõ Carlos, USP, Saõ Carlos, SP, Brasil, G. Punte, LANADI y PROFIMO, Depto. de Física, UNLP, CC 67, (1900) La Plata, Argentina, J.C. Autino, LADECOM, Depto. de Química, UNLP, Argentina and C.C. Wilson, ISIS Facility, CLRC Rutherford Appleton Laboratory, Chilton, Didcot, Oxon OX11 0QX, UK.

Much effort has been devoted in the last decade to the study, design and understanding of the aggregation of organic molecules. The considerable interest in the field has been based on the fact that crystal engineering, the ability to predict and/or direct the three-dimensional arrangement, can be used to tailor materials of biological or technological importance. Intermolecular hydrogen bonds are an effective tool for organising molecules, and in the case of non-linear optical compounds this is very well typified by nitroaniline compounds, which associate via intermolecular H-bonds between the amino and nitro groups. Nitroanilines have received special attention due to their recognized second harmonic generation capability and their large microscopic hyperpolarizabilities. In addition, aniline planarity has been backed by most organic text book assumptions and even by surveys of the geometry of unsubstituted and substituted aromatic amines. We will present here results from single crystal neutron diffraction experiments on 2-methyl-5-nitroaniline and *m*-nitroaniline performed on the SXD instrument at ISIS. The aim of these studies has been to establish the degree of planarity of the amino group and to add to the understanding of the role of the hydrogen bonds in the molecular organization of nitroanilines.

P09.06.021 HYDROGEN BONDED ADDUCTS BETWEEN TRIPHENYLSILANOL AND AROMATIC AMINES S.E. Lawrence, A. O'Dowd and T.R. Spalding Chemistry Department, University College Cork, Cork, Ireland.

Attention is currently focussed on the interaction between silanols and amines, spanning areas of interest from environmental silicon chemistry to siloxane polymers. Surprising, there have been few accounts concerning the hydrogen bonded adducts of tertiary silanols with amines, e.g. only adducts involving *N,N,N',N'*-tetramethylethylenediamine (TMEDA) and tris(2-aminoethyl)amine [1] have been discussed.

In this study we present crystal structures of the adducts formed between triphenylsilanol (Ph_3SiOH) and aromatic amines, such as 4,4'-bipyridyl and 4-phenylpyridine. Different structures are seen, depending on the silanol:amine ratio and the nature of the aromatic amine used, and these will be discussed.

P09.06.022 LOCALIZATION OF HYDROGEN AND H-BONDING IN CLUSTER CHALCOCYANIDE HYDRATES N.G. Naumov, N.K. Moroz, V.E.Fedorov, Institute of Inorganic Chemistry SB RAS, Novosibirsk, Russia.

Recently a new class of inorganic cyanides, namely, octahedral cluster rhenium chalcocyanides based on cluster anions $\{[Re_6Q_8](CN)_6\}^{4-}$ where Q=S, Se, Te was discovered. Several interesting compounds with intrigue compositions and structures were synthesized and characterized structurally. In much of them especially in the compounds containing large quantity of water molecules, for example, $(H_3O)_2Mn_3[Re_6Se_8(CN)_6]_2*23.5H_2O$, $(H_3O)_2Mn_3[Re_6Se_8(CN)_6]_2*14.5H_2O$, $Ba_2[Re_6Te_8(CN)_6]*12H_2O$, H-bonding is of crucial importance in stability and transformation of their structures. However, attempts to locate hydrogen atoms in such structures were unsuccessful.

We developed a new approach for this propose based on combination of X-ray data of heavy atom positions with 1Н solid state NMR as well as structure modelling. This allows us to determine hydrogen position in structure with accuracy typical for neutron diffraction method. We demonstrate here this approach on example of new cluster chalcocyanide hydrate $Ba_2Re_6Te_8(CN)_6*12H_2O$. The compound is crystallised with triclinic symmetry. In the structure barium atoms are co-ordinated by six water molecules bonded by two bridged water molecules in dimer $\{[Ba*5H_2O]_2\}^{4+}$; uncoordinated water is located in canals of structure which is running in [001] direction. A peculiarity of this structure implies that only half of protons is involved in H-bonding with characteristic distances about 2.78-2.86 A (O-H...O) and 2.92-3.13 A (O-H...N). The system of hydrogen bonds undergoes subsequent transformation with phase transitions at crystal heating. The approach developed seems very fruitful for complex crystalline hydrates.

P09.06.023 TWO ASPECTS OF CHIRALITY IN ORGANIC CRYSTALS RESULTING FROM OPTICAL ACTIVITY. K. Stadnicka, Faculty of Chemistry, Jagiellonian University, Ingardena 3, 30-060 Kraków, Poland.

Following the rules derived from the inspection of simple inorganic ionic structures [1] a relation between structure and optical rotation for several organic crystals, for which both the absolute structure and the gyration tensor are known, is traced. The discussion will concentrate on such structures as those of dirubidium (+) tartrate - $P3_221$, ammonium Rochelle salt - $P2_12_12$, L-glutamic acid (β-form) - $P2_12_12_1$, D-mannitol - $P2_12_12_1$, and L(+)-tartaric acid - $P2_1$, all of which are built of chiral molecules and are able to display optical activity when dissolved. In the presented examples, according to our earlier conclusions [2], there is a need to distinguish (in an analogy to polar crystals and polar directions) two meanings of chirality: the chirality of a finite object (like molecules or crystals - in the sense of their shape and habit) - invariable under the point group symmetry of proper rotations, and the chirality of specified directions in the crystal structure related to helical intermolecular arrangements of polarizable atoms. This approach seems to be in agreement with the extended definition of chirality by Whyte [3]. A comment will be made on the contribution of a single molecule to the gyration tensor of a given crystal [4] and on mutual relation between the orientation of the gyration surface and the optical idicatrix when these orientations are not fixed by symmetry.

P09.06.024 STRUCTURES AND SHORT HYDROGEN BONDS OF ACID SALTS OF GLUTACONIC ACID. S. Kashino [1], J. Taka [2], H. Ishida [1], [1]Department of Chemistry, Okayama University, Okayama 700-8530, Japan, [2]Institute for Protein Research, Osaka University, Suita 565-0871, Japan

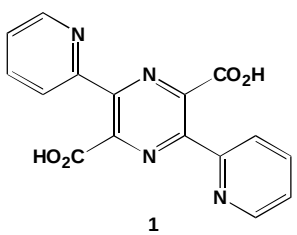
Patterns of short O-H…O hydrogen bonds were studied for acid salts potassium hydrogen glutaconate monohydrate (1), sodium hydrogen glutaconate (2) and ammonium hydrogen glutaconate (3). Two O-H…O hydrogen bonds in (1) are centrosymmetric and short. The hydrogen bonds in (2) and (3) are non-symmetric. The second order phase transition was observed for (1) around 265 K by the difference scanning calorimetry, while the transition was not observed for (2) and (3) in the temperature range of 173 to 323 K. The distances of hydrogen bonds and those of coordination involving the water molecule in (1) were significantly shorter at 40 K than 295 K. No other structural change including that of the short hydrogen bonds was significant for (1) between the two temperatures. The difference electron density maps around the short hydrogen bonds in (1) suggested that the O-H…O hydrogen bonds have single-minimum potential wells.

P09.06.025 STRUCTURE OF 2'-CHLOROAZO-BENZENE - 2 - SULPHENYL BROMIDES. Karmakar [1], A. N. Talukdar [2], P. Barman and S. Bhattacharjee [3], [1] University Science Instrumentation Centre (USIC), Gauhati University, Guwahati - 781 014. India, [2] Department of Physics, Gauhati University, Guwahati - 781 014. India, [3] Department of Chemistry, Gauhati University, Guwahati - 781 014. India

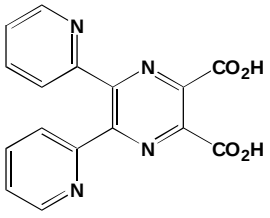
The title compound belongs to the marcaptoazo group which has biological activities to some plant pathogenic fungi. The compound has been undertaken in order to study the effect of ionisation of the Br atom on the azo group and to investigate the intermolecular hydrogen bond of the molecule. The compound crystallises in orthorhombic space group P $2_12_12_1$ with a=7.421(6); b =15.763 (2); c = 21.018(5)Å; V= 2458.63Å^3; Z = 8; λ =1.5418 A; D_0 = 1.77 ; D_x =1.76 gm /cm3 ; m =7.95 mm-1 ; F(000) = 1296; T=293 K ; R = .0620 for 2411 observed reflections. The two phenyl rings make angles of 0.87^0 and 45.82^0 with the central five membered ring. The Br -ion and the N7 atom makes H- bonding with symmetrically related C - H atoms of the adjacent molecule. The Cl 3 atom is in the plane passing through the phenyl ring to which it is attached.

P09.06.026 HYDROGEN BONDING IN BIS(2-PYRIDYL)-PYRAZINE-DICARBOXYLIC ACIDS. H. Stoeckli-Evans, M. Alfonso & Y. Wang, Institut de Chimie, Université de Neuchâtel, Av. de Bellevaux 51, CH-2000 Neuchâtel, Switzerland.

The ligands, 2,5-bis(2-pyridyl)-pyrazine-3,6-dicarboxylic acid (**1**) and 2,3-bis(2-pyridyl)-pyrazine-5,6-dicarboxylic acid (**2**) have been synthesized to study the formation of coordination polymers with first row transition metals. They both exhibit considerable diversity in their coordination modes. A prominent characteristic of these compounds is their amphoteric property. They have been shown to exist as inner salt zwitterions and as different charged species.



1



2

For compound **1** three forms have been isolated. The inner salt zwitterion, **1a**, a charged form **1b**, with both pyridine nitrogen atoms protonated, and, the neutral form, **1c**. For compound **2** three forms have also been prepared. The inner salt zwitterion **2a**, a charged form **2b**, with both pyridine nitrogen atoms protonated and one carboxylate group, and **2c,** a seconded charges species obtained as isomorphous ClO_4^- or PF_6^- salts.

The two inner salt zwitterions, **1a** and **2a**, both form hydrogen bonded polymers. **1a** is a double stranded cross-linked polymer while **2a** exhibits a channel type structure with hydrophobic walls and an hydrophyllic external base. The hydrogen bonding in all six compounds will be discussed.

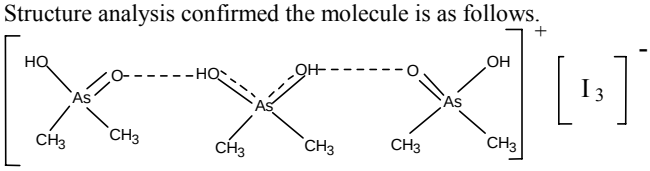
P09.06.027 HYDROGEN BONDING IN THE STRUCTURE OF TRIS-(HYDROXY-DIMETHYLARSINE OXIDE) HYDROGEN TRI-IODIDE. *Y. Iimura, *K. Yamanaka and *M. Hoshino, *The Institute of Physical and Chemical Research (RIKEN), 2-1 Horosawa, Wako-shi, Saitama, 351-0198 Japan and *Nihon University College of Pharmacy, Funabashi, Chiba, Japan.

We have studied the photochemistry of dimethylarsine iodide $(CH_3)_2AsI$, in aerated toluene containing 4.4 X10^{-3}M water. The toluene solution was irradiated for 5 hrs. The photochemical product form $(CH_3)_2AsI$ was recrystallized from chloroform solutions.The photoproduct was found to have the molecular structure with a unique hydrogen bond.

The crystal and molecular structure of the product has been determined by single-crystal X-ray analysis(Enraf-Nonius CAD4,MoK,omega-scan)

Crystal Data: $C_6H_{22}As_3I_3O_6$, Orthorhombic, Pbcn, a=5.6046(5), b=21.936(1), c=17.1464(8)Å, V=2108.0(2)Å^3, Z=4, R=0.035, Rw=0.063.

Structure analysis confirmed the molecule is as follows.



Intermolecular hydrogen bonds make a two dimensional network along a and c axis directions.

These result indicates that $(CH_3)_2AsI$ undergoes photodissociation of the As-I bond to yield $(CH_3)As$, which further reacts with oxygen and water resulting in the formation of $[(CH_3)_2AsO_2H]_3[HI_3]$.

P09.06.028 DISAPPEARING AND REAPPEARING POLYMORPHS J. Bernstein and A. Ellern, Department of Chemistry Ben-Gurion Universi-ty of the Negev, P.O. Box 653, Beer Sheva 84105, Israel, and J.-O. Henck, Institut für Pharmakognosie, Josef-Moeller-Haus, Universität Innsbruck Innrain 52, A-6020 Innsbruck, Austria

Polymorphism is a frequently observed phenomenon in molecular com-pounds. Since a particular polymorph may have desirable properties com-pared to its congeners, it may be required to develop a robust method to obtain that polymorphic modification consistently and reproducibly. Difficulties in obtaining crystals of a particular known modification or in re-producing results from another laboratory (or even one`s own) have had serious practical or economic consequences. We recently documented a number of representative cases in which it was difficult to obtain a given polymorphic form even though previously it had often been obtained routinely over long periods of time - so-called ‘disappearing poly-morphs’.[1] One of the

challenges to those dealing with the preparation of solids for any purpose is to be able to rationally develop the conditions to control the polymorphic form obtained - in many instances to recover a disappeared polymorph.

In the work reported here we employed methods of chemical and thermal microscopy along with thermal analysis to identify polymorphic forms and to provide guidelines for finding the conditions for the selective and controlled preparation of particular polymorphic forms of materials. The crystals so obtained were used to determine and compare the crystal structures of the various polymorphs.

P09.06.029 PHARMACEUTICAL APPLICATION OF HIGH TEMPERATURE XRD UNDER CONTROLLED RELATIVE HUMIDITY Suneel Rastogi and Raj Suryanarayanan, College of Pharmacy, University of Minnesota, Minneapolis, MN 55455, U.S.A. Marek Zakrzewski, Philips Analytical X-Ray, Almelo, The Netherlands (present address: Rhone-Poulenc Rorer, Collegeville, PA 19426, U.S.A.).

Solid-state reactions and phase transitions induced during pharmaceutical processing and storage can profoundly influence the performance of dosage forms. The objective of this study was to investigate the effects of temperature *and* water vapor pressure on the kinetics of complex decomposition reactions in solid pharmaceuticals. Thermoanalytical techniques have been widely used for the investigation of these reactions. High temperature XRD under controlled relative humidity is an excellent compliment to thermoanalytical techniques and provides critical information about the reaction mechanism. The studies were carried out in a θ-θ powder X-Ray diffractometer (Philips X-Pert MPD system) with a position-sensitive detector (Raytech®). The instrument was equipped with a high temperature attachment (TTK, Anton Paar) which was specially modified so that in addition to maintaining the sample at the chosen temperature, the atmosphere above the sample could be maintained at the desired relative humidity. The decomposition of aminophylline monohydrate (**I**) was studied at several temperatures (in the range of 60 and 115°C) over a range of RH values (0 to 80%). Aminophylline monohydrate (**I**) decomposes to anhydrous theophylline (**III**) either directly or through an intermediate phase (anhydrous aminophylline, **II**). The XRD patterns revealed that the lines with d-spacings of 8.26, 7.82 and 7.02 Å were unique to **I**, **II** and **III** respectively. By measuring the integrated intensities of these lines, it was possible to simultaneously quantify the three phases during the entire reaction. In the absence of water vapor (i.e. at 0 % RH), all the reaction steps followed first-order kinetics. The activation energies for the three reaction steps were determined from Arrhenius plots. The next step was to study the influence of water vapor pressure on the reaction kinetics and mechanism. The desired water vapor pressure in the sample chamber was rapidly attained using a prototype humidity generator. In the presence of water vapor, the intermediate phase was not detected suggesting that a direct transition from **I** to **III** is the major decomposition pathway. Under isothermal conditions, an increase in water vapor pressure resulted in an overall increase in the reaction rate.

P09.06.030 DISORDERED STRUCTURE OF A MIXTURE OF THE N-O^{-} RADICAL AND THE N-OH DERIVATIVE OF 6,6-BIS-(p-TOLYL)-5,6-DIHYDRO-PHENANTHRIDIN-N-OXYL. F. Iwasaki, M. Suzuki, D. Hashizume and M. Yasui, Dept. of Applied Physics and Chemistry, The Univ. of Electro-Communications, Chofu, Tokyo 182-8585, Japan.

In the course of studies on the structures of organic radical crystals showing magnetic interactions, an unusually long radical N-O bond (1.334 Å; normal radical N-O bonds = 1.28~9 Å) and a short intermolecular O···O contact (2.769 Å) were observed in the crystals from the batch I of 6,6'-bis-(p-tolyl)-5,6-dihydrophenanthridin-N-oxyl. Significant positive peaks were observed on the O···O line in the D-maps. Then we tried the intensity measurement again using a crystal obtained from a new batch (II). In this case, a normal N-O distance (1.282 Å) and an O···O van der Waals contact (2.979 Å) were observed at 140K. No peaks were observed on the O···O line in the D-maps. Detailed examinations showed that dimensions of the crystal lattice were slightly different between I and II.

	T/K	a/Å	b/Å	c/Å	β/Þ	V/Å^3	meas.	obs.	R
I	293	10.976(2)	13.112(2)	14.142(2)	105.00(1)	1966.0(5)	4512	2118	0.050
	150	10.905(2)	12.942(2)	14.099(2)	104.97(1)	1922.3(4)			
	100	10.876(3)	12.875(3)	14.095(2)	104.89(2)	1907.5(8)	4377	2471	0.046
II	300	10.938(3)	13.130(3)	14.173(2)	104.25(2)	1972.9(7)			
	140	10.852(4)	13.089(3)	14.023(2)	104.63(2)	1927.3(7)	4407	3366	0.041

These facts suggests that the first crystals (I) are constructed by the mixture of N-O radicals and their deactivated substances. A disordered structure, which contained radical N-O and N-O-H bonds with occupancy factors of 0.5, was refined using data at 100K. After an assignment of the peak on the O···O line of the D-map to the H atom attached to the non-radical O atom, the structure converged to the R value of 0.046. In the crystals of I, disoreded intermolecular hydrogen-bonds, N-O-H···O-N and N-O···H-O-N are formed. The geometry of the hydrogen-bond is: 2.755, 1.06, 1.76 Å and 154° for O···O, O-H, H···O and O-H···O, respectively. The disordered form is considered to be crystallized from the solution with trace water or inadequate activation during the synthesis. It is very interesting that the structure of the pure radical crystals is isomorphous with that being constructed by the hydrogen-bonding.

P09.06.031 A STUDY OF THE N(H…H(B HYDROGEN BOND INCLUDING THE CRYSTAL STRUCTURE OF BORANE-AMINE, BH3NH3, BY NEUTRON DIFFRACTION. T.F. Koetzle and W. T. Klooster, Chemistry Department, Brookhaven National Laboratory, P.O. Box 5000, Upton, NY 11973-5000, USA, and P.E.M. Siegbahn, Department of Physics, Stockholm University, Box 7630, S-113 85 Stockholm, Sweden, and T.B. Richardson and R.H. Crabtree, Chemistry Department, Yale University, New Haven, CT 06520-8107, USA.

Borane-amines tend to have close H···H contacts as a result of the intermolecular interaction of the NH proton with the BH bond. The strength of this type of interaction, which is sometimes called a *dihydrogen bond*, has been suggested to be 4-6 kcal/mol - a value comparable to that for a classical hydrogen bond.

A CSD search provides characteristic metric data for the N-H···H-B interaction: The H-H distance is in the range 1.7-2.2 Å, and the N-H···H group tends to be linear (150°), while B···H-H tends to be bent (95°-115°). The structure of BH_3NH_3 reported in the literature seemed to be a singular exception in having bent N-H···H and linear B···H-H. Our neutron diffraction study of BH_3NH_3 now reveals the source of the problem: B and N have been interchanged in the published x-ray structure. With the correct assignment we obtain angles of N-H···H 156(3)° and B···H-H 106(1)° in the close (d_{HH} 2.02(3) Å) intermolecular N-H···H-B interaction, as expected.

This work was supported by the US DOE Office of Basic Energy Sciences, under contract DE-AC02-98CH10886, and by the US NSF.

P13.06.001 INCLUSION COMPOUNDS OF AN ACETYLENIC ALCOHOL HOST A.Jacobs, M.R.Caira, L.R.Nassimbeni, Department of Chemistry, University of Cape Town, Rondebosch 7701, South Africa

The inclusion behaviour of the host compound 1,1,6,6-tetraphenyl-hexa-2,4-diyne-1,6-diol was studied. Host-guest complexation was observed between the above host and the guests: carbon-tetrachloride, acetonitrile, pyridine and 3-picolene. The crystal structures of these inclusion compounds were elucidated using single crystal X-ray diffraction. Hydrogen bonding between the host and the guest was observed for those guests that had functional groups suitable for hydrogen bonding. ie. acetonitrile, pyridine and 3-picolene. Intermolecular hydrogen bonding between the hydroxy moieties of the host molecules was observed in the inclusion compound formed with carbon-tetrachloride. Thermogravimetric analysis (TGA) was used to determine the stoichiometry of the inclusion compounds. Thermal changes in the complexes were monitored using differential scanning calorimetry (DSC). Kinetics of desolvation of these compounds were studied and the activation energies were interpreted in terms of the host-guest packing.

P13.06.002 CHIRAL RECOGNITION AND CRYSTAL STRUCTURES OF DCA INCLUSION COMPOUND WITH LIMONENE. M.I. Mohamed Tahir and C.K. Prout, Chemical Crystallography Laboratory, 9 Parks Road, Oxford OX1 3PD,UK, S. Mahey and S.J. Heyes, Inorganic Chemistry Laboratory, South Parks Road, Oxford OX1 3QR,UK.

Chiral recognition of guests by host lattices of inclusion compounds is an important property and yet to be fully understood. Deoxycholic acid (DCA) as host studied, provides tunnels or channels which are chiral in the lattices. The channels are hydrophobic and resides between adjacent bilayers of DCA molecules connected through hydrogen bonding. Due to the hydrophobic nature of the channels most of the guests that have been studied are organic compounds.

The inclusion compounds of the 2:1 complex between DCA and R,S,RS-limonene (DCRLIM, DCSLIM, DCRSLIM) have been examined by CP/MAS ^{13}C NMR. At ambient temperature the NMR spectrum shows that each inclusion compound contains two DCA molecules in the asymmetric unit and that the spectrum of the DCRSLIM is the sum of the spectra DCRLIM and DCSLIM. This suggests that the DCRSLIM compounds consists of separate crystallites of DCSLIM and DCRLIM complexes. The VT CP/MAS ^{13}C NMR suggests a phase change above room temperature to a form with only one DCA molecule in the asymmetric unit.

We are examining the crystals structures of these compounds crystallographically. Preliminary results indicate the compounds to be monoclinic at ambient temperature similar to the low temperature form of DCA with d-camphor (DCRLIM: $P2_1$, a=7.27, b=13.82, c=26.63 Å, γ=90.10º, DCSLIM: $P2_1$, a=7.29, b=13.89, c=26.40 Å, γ=90.21º). However, for the limonene complex the unique axis is c whereas for d-camphor the unique axis is b.

P13.06.003 CONTROL OF MOLECULAR CAVITIES BY SIDE CHAIN LENGTH OF CHOLIC ACID M. Sugahara, K. Sada, and M. Miyata, Material and Life Science, Graduate School of Engineering, Osaka University, Yamadaoka, Suita, Osaka 565-0871, Japan.

Molecular design of organic crystalline materials that have nanocavities with controlled size, shape, chirality and chemical environment, is of great interest in organic solid state chemistry [1]. However, fine-tuning of nanocavities is in its infancy. For example, it is difficult to design relatively large cavities without changing 3D framework against chemical modification. We present here a novel strategy for controlling nanocavities due to different side chain length of cholic acid (CA). CA with one or two more methylene units is called homocholic acid or bishomocholic acid (BHCA), respectively.

Their inclusion crystals have been obtained by re-crystallisation from various organic compounds. It was found that BHCA included organic compounds, such as naphthalene derivatives, with a 1:1 molar ratio. X-ray diffraction studies made clear that BHCA forms a similar bilayered structure [2] to CA, indicating that both the hosts form the robust motif. Detailed comparison indicates that BHCA with 1-methylnaphthalene forms larger interlayered channels than CA with benzene. Such a difference might be explained by similar conformations of the side chains. The terminal carboxy groups have similar direction, and the substantial length of the chains are different.

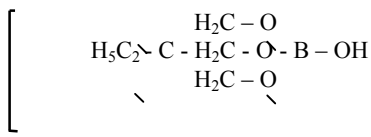
P13.06.004 SYNTHESIS AND CRYSTAL STRUCTURE OF SODIUM 1,1,1-TRIMETHYLOLPROPANE BORATE TRIHYDRATE. I.Zviedre and J.Schwartz, Institute of Inorganic Chemistry of the Riga Technical University, Riga, Latvia, and V.Belsky, L.Karpov Institute of Physical Chemistry, Moscow, 103064, Russia.

In the interaction of boric acid with polyhydroxy compounds the spiran-tipe 1:2 and 1:1 complexes containing bidentatic ligands are formed. When ligand possess more than two hydroxyl groups, the possibility to form the cage complexes containing tridentatic ligand appears. The latter complexes are synthesized from cyclitols, e.g. from scyllo-inositol, and the crystal structure of $Na_2(C_6H_8B_2O_8)\cdot 10H_2O$ has been determined [1]. Boric acid with β,β^1- triols can form complexes containing bidentatically as well as tridentatically coordinated ligands. Data on the structure of the tridentatic cage complexes 1:1 are indirect. The monocrystals of $Na[C_2H_5C(CH_2O)_3BOH]\cdot 3H_2O$ were obtained using the modified synthesis method [2].



In the complex anion (Fig.) the boron atom is bonded to ligand via three O atoms, (the B-O bond lengths being 1.475 ÷ 1.501Å) and to OH (1.401 Å). The O-C distances are of 1.407 ÷ 1.414 Å. Four O-B-O bond angles are of 108.2^0 in average, the two other (exocyclic) are 112.8^0 and 113.4^0; angles C-O-B and C-C-C amounting to 110.9^0 and 106.7^0 in average, respectively. Three six-membered heterocycles -C-C$^{/}$-C-O-B-O- are inflected along the C$^{/}$-B axis with which they are mutually conjugated. Each Na^+ ion is octahedrally coordinated with O atoms of five water molecules (Na...O distances 2.318 ÷ 2.513 Å) and one hydroxyl group (2.365 Å). In the crystals the anions form with NaO_6 octahedra bilayer parallel to the *ab* plane. Lattice parameters: a=6.9310(10) Å; b=6.2680(10) Å; c=27.053(5) Å; β=93.37(3)°, V=1173.2(3) Å^3; Z=4; ρ_c=1.336 g/cm^3; sp.gr. $P2_1/c$; R=0.0527; R_w=0.1198.

P13.06.005 PHASE TRANSITIONS IN THE THIOUREA CYCLOOCTANE INCLUSION COMPOUND. T. Maris, M.J. Henson and C.K. Prout, Chemical Crystallography Laboratory, 9 Parks Road, Oxford, OX1 3PD, UK, and S.J. Heyes, Inorganic Chemistry Laboratory, South Parks Road, Oxford, OX1 3QR, UK.

Thiourea is known to form inclusion compounds with a host lattice made of channels with an approximate diameter of 6.1 Å. These channels can accommodate large guest molecules such as long branched hydrocarbons and cycloalkanes. In general, the room temperature crystal structure of the adducts is rhombohedral and the guest molecule is usually found in a substantially disordered state.

Variable temperature single X-ray experiments have been performed on the thiourea cyclooctane adduct and show three different phases. In addition to the classical rhombohedral room temperature form and the monoclinic low temperature phase, which usually exists in several cycloalkanes-thiourea clathrate, a supplementary monoclinic phase having a doubled b axis can be observed at lower temperature.

A single X-ray crystallographic characterisation has been performed for each of these three phases. As expected in the rhombohedral room temperature form (a = 16.223(2) Å, c = 12.493(4) Å), the cyclooctane guest molecule is highly disordered. In the intermediate monoclinic phase, (T = 210 K, $P2_1/c$, a = 12.468(4), b = 15.551(7) Å, c = 10.397(3) Å, β = 114.01(2)°) the cyclooctane seems to be disordered between two main conformations. In the lower temperature phase (T = 150 K, $P2_1/c$, a = 12.416(1), b = 30.918(2) Å, c = 10.371(1) Å, β = 113.85(1)°), the structure shows two cyclooctane rings having the same conformation but different orientations within the channels. These results are completed by solid state NMR experiment for probing the conformational dynamics of the guest molecules.

P13.06.006 GUEST-DEPENDENT VERSATILITY IN CRYSTALS OF A BULKY, CYCLOPROPANE-BASED DICARBOXYLIC ACID HOST Petra Bombicz[a], Ingeborg Csöregh[b], Mátyás Czugler[a], Alajos Kálmán[a]. H

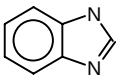
G1



G2

H : G1 = 1 : 2

H : G2 = 1 : 1

Wide variation of the host-host and host-guest interactions depending on the guest character has been observed in the crystalline heteromolecular complexes to be presented. Bulky cyclopropane-based hosts (*cf.* scheme) proved to be efficient in inclusion formation with aprotic and polar guests. The recognition of the DMSO guest (***G1***) involves strong *(CO)O-H...O=S* bonds and *(-CH2)-H...O=C* type interactions. One of the solvent molecules is enclathrated in a cage formed by four host molecules (***H***) *via C-H...π* interactions, while the other one is in a separate layer and shows partial disorder. Following the dissolution of the ***H:G1*** clathrate crystals in a benzimidazole containing ethanol solution, the benzimidazole guest (***G2***) has displaced the DMSO molecules, thus forming ***H:G2*** co-crystals with fundamentally altered host-host and host-guest interactions, hence with completely different packing arrangement. The host forms an infinite chain *via* strong *O-H...O* interactions of the carboxyl groups perpendicular to the fluorenes' plane. Fluorene and benzimidazole aromatic rings are parallel and have *π...π* intermolecular interactions. In the host molecule the rigidly maintained, ideal bisecting conformation of the aromatic moiety with the cyclopropyl ring makes electronic effects possible. This leads to lengthened vicinal bonds and to a shortened distal bond in the cyclopropane moiety. This bisecting conformation is also stabilised by an intramolecular *C-H...O* interaction.

P13.06.007 ORGANOALKALI METAL COMPLEXES FOR ORGANIC SYNTHESIS P. Williard, P. Williard, C. Sun, M. Jacobson, D. Walther, Department of Chemistry, Brown University, Providence, Rhode Island, 02912 USA & Department of Pure and Applied Chemistry, 295 Cathedral Street, Strathclyde University, Glasgow G1 1XL, United Kingdom

Several examples of organo alkali metal complexes containing different alkali metal cations, e.g. Li, Na and/or K, and some extremely widely used carbanions such as enolate anions and amide bases will be presented. Complexes of n-butyl lithium, the most commonly utilized alkyl lithium reagent throughout the world, with chiral amide ligands will be presented. We will describe the structures of some new complexes of amide bases and carbanions that are used in enantioselective reactions. An overall scheme which incorporates this aggregated structures into a reaction pathway will be presented. Some solution phase NMR data will serve to correlate the solid state structures with the corresponding species that exist in solution.

P13.06.008 CONTROL OF THE CRYSTALLINE-STATE PHOTORACEMIZATION BY FORMING THE HOST-GUEST COMPLEXES A. Sekine, N. Sugimoto, H. Aoki, T. Suzuki, H. Uekusa, Y. Ohashi, Department of Chemistry, Tokyo Institute of Technology, Tokyo 152-8551, Japan

It has found that the chiral 1-cyanoethyl group in cobaloxime complexes is racemized on the exposure to visible light with reteintion of the single crystal form. A serises of the cobaloxime complexes have been examined so far.

In order to control the reactivity we tried to make the host-guest complex using the chiral 1-cyanoethyl cobaloxmie crystals as a guest. The two host-guest crystals were obtained using dicyclohexylamine(1) and cyclohexylheptylamine(2) as host molecules. The chiral 1-cyanoethyl groups in the two host-guest complexes as well as the pure guest complex(3) were racemized with retaining the single crystal form on exposure to a xenon lamp. The crystal structures were analysed before and after the irradiation. The racemization rates of the crystals were estimated from the change of the HPLC peaks. The rate constants obtained assuming first-order kinetics are significantly different from each other. The analyzed structures indicate that the different reaction rates have a quantitative correlation with the volumes of the reaction cavities for the 1-cyanoethyl groups in the crystals. The reaction rate can be controlled by the host-guest complexes and/or changing the host molecules.

P13.06.009 SELECTIVE COMPLEXATION OF CEPHALOSPORIN ANTIBIOTICS R. de Gelder, G.J. Kemperman, F.J. Dommerholt, A.J.H. Klunder, B. Zwanenburg [1] [1] NSR Centre for Molecular Structure, Design and Synthesis, University of Nijmegen, Toernooiveld, 6525 ED Nijmegen, The Netherlands

The Cephalosporin derivatives Cephalexin, Cephradine, Cefaclor and Cefadroxil are widely used life-saving antibiotics. Isolation and purification of these compounds by means of selective complexation, e.g. using beta-naphtol [1], is a powerful

method, however, despite its industrial relevance, the mechanism and the structural details of the resulting complexes are unknown.

We have studied the complexation behaviour of the cephalosporins for a large variety of naphthalene derivatives and investigated the structures using X-ray diffraction. The complexes formed appeared to be inclusion compounds of the clathrate type in which the antibiotic molecules form a host lattice and the complexing agents play the role of guest.

A remarkable isomorphism is found for three of the cephalosporins. The different behaviour and selectivity of the fourth one, Cefadroxil, is explained on the basis of the crystal structures of the complexes.

P13.06.010 INCLUSION COMPOUNDS BETWEEN APOCHO-LIC ACID AND POLYETHERS. K. Suehiro, R. Kishikawa, K. Matsushita, and M. Kuramori, Department of Chemistry and Applied Chemistry, Faculty of Science and Engineering, Saga University, Saga 840-8502, Japan

A large number of inclusion compounds of deoxycholic acid (DCA), apocholic acid (ACA), and cholic acid (CA) with small organic molecules have been prepared and characterized [1-3]. Unlike DCA, CA does not form inclusion compounds with polyethers. In the present study, the preparation of inclusion complexes of ACA with aliphatic polyethers was examined.

ACA was prepared by dehydration of CA in the presence of ZnCl2 in acetone solution. Complexation was attempted by slow evaporation of solvent from ethanolic solutions of ACA and polyethers.

Crystalline inclusion compounds were obtained for polyethers such as poly(propylene glycol), polytetrahydrofuran, poly(ethylene glycol) mono-stearate. These crystals belong to the orthorhombic space group $P212121$. The cell dimensions are: a = 25.15, b = 13.95, c = 7.42; a = 25.00, b = 13.78, c = 7.49 Å for the poly(propylene glycol) and polytetrahydrofuran complexes, respectively. Four ACA molecules are contained in the unit cell and two polymer chains pass through it in parallel with the c axis. The structure of these crystals is analogous to that of the orthorhombic inclusion compounds of DCA [2, 4].

ACA crystal that contains no guest molecules is also orthorhombic and has the same space group. The cell dimensions determined from powder X-ray diffraction patterns are: a = 21.97, b = 14.21, and c = 7.54 Å . The a axis is approximately 12% shorter than that of the inclusion crystals, due to the absence of the guest molecules, whereas the b and c axes are only a few percent longer. The ACA molecules are thought to form a bilayer; however no channels were observed.

P13.06.011 POLYMORPHISM IN CLATHRATE STRUCTURES. T.H. Brehmer, W. Seichter, S. Nitsche, T. Hens & E. Weber, Organic Chemistry, TU Freiberg, D-09596 Freiberg, Germany and F.H. Cano, Crystalografía, Rocasolano (CSIC), E-28006 Madrid, Spain.

It is a well known fact that the solvent of crystallization may determine the packing arrangement in crystal structures and lead to polymorphism. In particular this is true in inclusion crystals, where host molecules are capable to change their conformation or association mode to fit a guest compound into the host lattice. Host molecule **1** based on the characteristic 9,10-diethy-nylanthracene[1] subunit and appended 9-fluorenol clathratogenic groups has been synthesized and studied with regard to their crystalline inclusions involving acetone, DMSO and N,N´-DMF as guest molecules. All three crystal structures show a host guest ratio of 1:2 and crystallize with two molecules per asymmetric unit. However the conformation of **1** differs and thus also the crystallographic symmetry. This change is caused by the different solvent polarities, while the molecular geometry of the guests is rather similar. In the monoclinic clathrate structure **1**•acetone [$P2_1/c$; a=8.475(3), b=8.237(3), c=27.974(3)Å, β=90.746(3)°; V=1952.7(1)Å^3] the terminal 9-fluorenol groups point at opposite directions making the host molecule to adopt an *anti*-conformation with a centre of symmetry in the anthracene unit. On the other hand, the host molecule shows an identical *syn*-conformation, in the two triclinic clathrate structures, **1**•DMSO [P-1; a=15.4476(9), b=11.6576(6), c=11.2357(6) Å, α=105.702(4), β=82.360(4), γ=98.378(5)°; V=1917.7(2) Å3] and **1**•DMF [P-1; a=15.9748(2), b=11.5648(3), c=11.1881(2) Å, α=105.67(2), β=85.04(3), γ=97.00(4)°; V=1972.19(3) Å^3]. The two triclinic structures are isostructural, including the same type of dimer motif between two guest molecules [graph set $R_2^2(8)$] linking two host molecules by means of O-H...O hydrogen bonding. The structures will be discussed in terms of conformation-polymorphism, pseudo-polymorphism and guest-dependent polymorphism.

P13.06.013 CRYSTAL STRUCTURE OF FURAN CLATHRATE HYDRATE FROM NEUTRON POWDER DIFFRACTION DATA. T. H. Plumridge and R. D. Waigh, Department of Pharmaceutical Sciences, University of Strathclyde, Glasgow G4 0NR, UK, G. Steele, Astra Charnwood, Bakewell Rd, Loughborough LE11 5RH, UK, and K. S. Knight, ISIS Facility, CLRC Rutherford Appleton Laboratory, Chilton, Didcot, Oxon, OX11 0QX, UK.

Hydrate inclusion compounds are solid crystalline complexes in which various types of guest molecule are accommodated inside regular cage structures formed by hydrogen-bonded water molecules. Clathrate hydrates are the simplest of these, and although these compounds were first prepared in the 1950s, only a handful of crystal structures have ever been investigated[e.g.1,2]. Here we report a structural investigation of furan clathrate hydrate. The hydrate was prepared by mixing deuterated furan and deuterated water in a ratio (C_4D_4O .17D_2O) corresponding to the stoichiometry of a previous crystallographic study of tetrahydrofuran clathrate[2] and cooling to 6.9^{O}C. DSC scans of the resulting crystals showed the sample to contain some, but not much, ice Because of the extensive hydrogen-bonding in clathrate systems, neutron diffraction is the preferred method for structural analysis. The structure of the furan clathrate at 4.2, 100, and 200K was refined using data collected from a deuterated sample on HRPD, the high resolution powder diffractometer at the *ISIS* facility of the Rutherford Appleton Laboratory, and is presented here.

P13.06.014 INTERACTIONS GUEST-HOST AND HOST-GUEST IN SELECTED ORGANIC ZEOLITE NETWORKS. J.Pielaszek(1), A.Yu.Manakov(2) and J.Lipkowski(1), (1)-Institute of Physical Chemistry, Polish Academy of Sciences, Warszawa, Poland, (2)-Institute of Inorganic Chemistry, Siberian Branch of Russian Academy of Sciences, Novosibirsk, Russia.

Analysis of changes in the structure of host lattice of eleven β-[$Ni(NCS)_2$(4- methylpyridine)$_4$] clathrates (known to have the organic zeolite type structure) on inclusion of different guest molecules was performed.

In-situ XRD patterns were recorded for a series of the clathrates subjected to saturation by different guest molecules at different temperatures: 150, 175, 200 and 300 K. The patterns were interpreted in terms of clathrate lattice expansion-contraction on absorption-desorption of the guest component. EENY [1] program was used for calculations of the intermolecular energy (the Empirical Force Field approach) and CRYSRULER [2] and XP [3] for calculations of the bond angles, torsion angles, interatomic distances and for the analysis of the molecular structures whereas an original algorithm was used for calculations of volume and linear sizes of the „free space" within a clathrate lattice.

Generalization of the obtained data allowed to put forward a model of the changes of the host-host interactions in the studied compounds as a function of the amount of absorbed guest.

P13.06.015 INCLUSION COMPOUNDS OF ALKALINE-EARTH METAL O,O'-DIBENZOYL TARTRATES. Luigi R Nassimbeni, Hong Su, Department of Chemistry, University of Cape Town, Rondebosch 7701, South Africa

Mg, Ca and Sr salts of (2R,3R)-(-)-O,O'-dibenzoyltartaric acid with methoxyethanol, ethanol and water have been synthesized and characterized by X-ray, thermal and spectroscopic methods: 1: Mg . DBT . ME. E. 3H2O 2: Ca . DBT . 2(ME) . H2O ME = Methoxyethanol; E = Ethanol 3: Sr . DBT . 2(ME) . H2O The crystal structures of the three compounds have been elucidated and their thermal stabilities have been measured using Thermal Gravimetry (TG) and Differential Scanning Calorimetry (DSC). In particular, compound 2 exhibits two distinct mass loss steps (TG) the first of which is endothermic and the second is exothermic (DSC). In order to fully characterize the thermal decomposition of this compound we caried out Evolved Gas Analysis (EGA). The IR spectra recorded during the mass loss steps identified methoxyethanol as the first compound to desolvate, followed by carbon dioxide in the second step.

P13.06.016 ALKALI METAL ION RECOGNITION BY FLUORESCENT SIGNALLING CROWN ETHERS. J.F. Malone, A.P. de Silva, D.G. MacKerracher and T.S. Moody, School of Chemistry, The Queen's University of Belfast, Belfast BT9 5AG, Northern Ireland, UK.

Complex life processes often depend on a few simple cations, *e.g.* protons in bioenergetics, sodium and potassium in membrane potential generation and calcium ions in intracellular signalling. Therefore the development of cation sensors is important for pure biological studies and finds wide application in the medical and biotechnological fields. The field of fluorescent sensors has developed to the point where a range of inorganic cations can be targeted successfully [1].

Many Group I and II metal sensors and switches rely on photo-induced electron transfer (PET) for sensing purposes, *e.g.* by the 'off-on' switching of fluorescence. N-(9-anthryl-methyl)monoaza-18-crown-6 and the 15-crown-5 analogue are very weakly fluorescent in methanol solution in the presence of proton scavengers. Addition of sodium or potassium, but not lithium, ions results in an enhancement of the fluorescence. The anthracene fluorescence, which is quenched by PET from the lone pair of the nitrogen in the metal free receptor, is recovered upon encapsulation of Na^+/K^+ into the monoaza crown ether, with flourescence enhancement (FE) of up to 47 [2].

A number of crystal structures of both metal-free and metal-bound azacrowns have been determined. Structures presented will include metal free N-(9-anthryl-methyl)diethanolamine, N-(9-anthryl-methyl)monoaza-15-crown-5 and N-(9-anthryl-methyl)monoaza-18-crown-6, and the same azacrowns bound to metal ions.

07. CRYSTALLOGRAPHY OF ORGANOMETALLIC, CO-ORDINATION, MAIN GROUP COMPOUNDS

P06.07.001 STRUCTURAL CHARACTERIZATION OF SYNTHETIC Mo-COFACTOR OF SULFITE OXIDASE. Nirmalya Prasun Nayak & Alok Kumar Mukherjee, Department of Physics, Jadavpur University, Calcutta 700 032, INDIA.

X-ray crystallographic study of coordination of the Mo-cofactor (MoCo) in chicken liver sulfite oxidase provides vital informations regarding the early failures to isolate pure Moco from its apoprotien and to synthesize a structural analogue of Moco. During our study on synthetic analogues of Mo-Cofactor oxidised sulfite oxidase we have isolated $[Bu_4N]_2[\{Mo^VO(S_2$-dithiolene) $(SPh)\}_2\mu(O)]$ **(1)** and its bromo analogue $[Bu_4N]_2[\{Mo^VO(S_2$-dithiolene) $(Br)\}_2\mu(O)]$ **(2)**. X-structure determinations of **(1)** and **(2)** revealed that the anions contained a linear Mo - O- Mo bridging unit with crystallographically imposed center of symmetry and the terminal oxo-group being Trans to each other. The bridging oxygen atom was located at the inversion center and the asymmetric units of **(1)** and **(2)** comprised of half of the anions and one $[Bu_4N]^+$ cation respectively . Each crystallographic independent Mo atom in **(1)** and **(2)** is penta coordinated in a distorted square pyramidal arrangement with the terminal oxo-group occupying the axial positions. In **(1)** the equatorial positions were occupied by two dithiolene sulfurs, one thiolate sulfur and one oxo bridged ligation while in **(2)** thiolate sulfur being replaced by a Bromine atom. The structural features of both the complexes are identical to the reported structure of Moco of native sulfite oxidase in respect to Mo coordinate sphere. The final crystallographic R-values for complex (1) and (2) were 0.0538 and 0.0578 respectively.

P06.07.002 LANTHANIDE COMPLEXES OF CARBOXYETHYL DOTA – DISPARITY BETWEEN STRUCTURE IN SOLID AND SOLUTION. Janet M. Moloney, Mark Woods, Judith A.K. Howard and David Parker. Department of Chemistry, University of Durham, Durham, DH1 3LE, U.K.

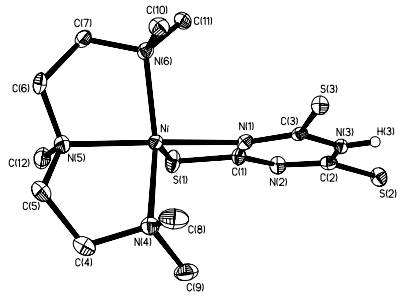
The co-ordination chemistry of the lanthanide ions with octadentate ligands derived from 1,4,7,10-tetraazacyclododecane has been documented comprehensively. The archetypal ligand for lanthanide elements, 'dota', forms kinetically robust complexes *in vivo*, and when tetra-*N*-substituted with phosphinate or carboxamide yields complexes with applications in MRI and targeted radiotherapy.

This poster will report on the structures of a new series of lanthanide complexes of 'dota' derivatives, namely the tetra(carboxyethyl) derivatives. In these complexes, there are two independent elements of chirality defined by the N-C-C-N and N-C-C-O torsion angles. The predominant isomer in solution epimerises and the minor isomer crystallises preferentially. The structures of the europium [1], gadolinium and terbium complexes exhibit remarkable structural similarity binding to the faces of a square antiprism and binding one additional water molecule whereas preliminary results suggest that the smaller ytterbium complex remains eight co-ordinate.

J.A.K. Howard, A.M. Kenwright, J.M. Moloney, D. Parker, M. Port, M. Navet, O. Rousseau and M. Woods. *J. Chem. Soc. Chem. Commun.,* 1998, 1381.

P06.07.003 SYNTHESIS AND CRYSTAL STRUCTURE OF Ni(II) COMPLEX WITH TRITHIOCYANURIC ACID. Z. Trávníček and P. Kopel, Dept. of Inorganic and Physical Chemistry, Palacký University, 771 47 Olomouc, CZ, and J. Marek, X-Ray Laboratory of Dept. of Inorganic Chemistry & Laboratory of Biomolecular Structure and Dynamics, Masaryk University, 611 37 Brno, CZ.

We are engaged in the synthesis and structures of nickel(II) complexes with trithiocyanuric acid and various nitrogen-donor ligands [1,2]. The [Ni(ttcH)(pmdien)] complex has been isolated in form of green crystals *via* reaction of $NiCl_2.6H_2O$ and *pmdien* (N,N,N′,N′,N″ -pentamethyldiethylene-triamine) in ethanol with water solution of *ttcNa*$_3$ (trisodium salt of trithiocyanuric acid) and 0.1M HCl. The structure was determined by X-ray diffraction and it was found that nickel atom is five coordinated in distorted trigonal bipyramidal arrangement. X-ray structural parameters we want to confront with quantum chemistry *semi-empirical* and *ab initio* calculations.



Crystal data and structure refinement: $C_{12}H_{24}N_6NiS_3$, monoclinic crystal system, $P2_1/n$, a = 12.496(7) Å, b = 9.226(2) Å, c = 16.385(4) Å, β = 111.46(4)°, V = 1758.0(11) Å^3, Z = 4, M_r = 407.26, T = 150 K, d_x = 1.539 g/cm^3, λ = 0.71073 Å, μ = 1.464 mm^{-1}, *F(000)* = 856, reflection collected / unique 3115 / 2974, [R(int) = 0.0401], R indices [I > 2σ(I)], *R1* = 0.0526, *wR2* = 0.1518, and the largest diff. peak and hole 1.230 e.Å^{-3} [0.99 Å from Ni] and –0.790 e.Å^{-3} [1.01 Ĺ from S1].

P06.07.004 STRUCTURAL DETAILS OF MAMMALIAN BONE MINERAL REVEALED BY RIETVELD ANALYSIS. P. Zioupos and K.D.Rogers, Department of Materials & Medical Sciences, Cranfield University, Shrivenham, Swindon, Wiltshire SN6 8LA, U.K.

Bone is a composite, multifunctional material that possesses both chemical and mechanical properties that are critically dependent upon its mineral component structure. However, the minerals' natural form (e.g. its small crystallite size, non-stoichiometry and inhomogeneity) has continued to provide difficulties for crystallographic, diffraction interpretation.

Using a combination of laboratory and synchrotron powder X-ray diffraction, we have applied Rietveld analysis to data produced from specimens of human femur, bovine femur, tympanic bulla of a blue whale and the rostrum of Mesoplodon densirostris. This particular species of whale has been shown previously to possess the greatest density of bone available in

nature and we have utilised it to model the effects of hypermineralisation. The mineral has been examined in situ and in a homogenised form. Microstructural features such as preferred orientation and average crystallite morphology have been determined. Rietveld analysis has also enabled us compare distortions in the atomic structures due to heteroionic substitutions such as carbonate. The findings are further supported by FTIR characterisation.

We have found that the rostrum is an extreme biological mineral, both in terms of its crystallite morphology and texture. Further, we believe that we have identified 2 populations of rostrum crystallites which may be distinguished by their degree of texture and heteroionic substitution. In contrast, the mineral of the bulla and femur, possess significantly lower degrees of preferred orientation and smaller crystallites. Optical microscopy of the rostrum also revealed signs of accelerated 'ageing' and an extensive degree of secondary remodelling with compacted osteons of a very atypical unidirectional nature.

P06.07.005 DIFFERENT CRYSTAL STRUCTURES OF THE Ln(DOTA) COMPLEXES. G. Bombieri, Istituto di Chimica Farmaceutica, Università di Milano, I and F. Benetollo, ICTIMA - CNR, Padova, I and S. Aime and M. Botta, Dipartimento di Chimica, Università di Torino, I and L. Calabi, Bracco Spa, Milano, I.

Ln(III) complexes with the octadentate ligand DOTA (H_4DOTA = 1,4,7,10 tetraazacyclododecane-N,N',N'',N'''-tetraacetic acid) are having a great deal of interest in view of their use in diagnostic techniques. An isostructural series of complexes $Na[M(DOTA)(H_2O)]\cdot 4H_2O$ (M= Y^1, $Eu^{2a,b}$ Gd^3, Ho^{2b} and Lu^4) is known, as well a new polymeric structure $Na[La(DOTA)La(HDOTA)]\cdot 10H_2O$[5]. Continuing our investigations we have obtained crystals of Ce, Pr, Nd, Dy and Tm of formula $Na[Ce(DOTA)(H_2O)]NaHCO_3\cdot 7H_2O$, $Na[Ln(DOTA).(H_2O)]\cdot 4H_2O$ (Ln = Pr, Nd), $Na[Dy(DOTA)(H_2O)]NaOH\cdot 7H_2O$ and $K[Tm(DOTA)]\cdot 6H_2O$ respectively. The structural results will be presented and discussed in the context of the different isomeric forms found in solution.

P07.07.001 CRYSTALLOCHEMICAL INVESTIGATION OF THE COORDINATION COMPOUND OF SCHIFF-BASE WITH CHROMIUM(III) CHLORIDE. G.Y.S.K. Swamy and K. Ravikumar, Laboratory of Crystallography, Indian Institute of Chemical Technology, Hyderabad 500 007, INDIA.

This communication discusses the problem into two ways.

1). Synthesis and structure elucidation of the title molecule through X-ray single crystal method.

2). Further confirmation of the structure through other spectroscopic techniques like UV, IR etc.

The complex crystallizes in the space group $P2_1/n$, with cell parameters a=10.017(2)Å, b=25.136(4)Å, c=10.582(2)Å , β=115.4(2)°, Z=4 and Mr=2055.8. The structure has been solved by patterson and subsequent Fourier synthesis led to an R = 0.045. The structure consists of discrete [bis(N-salicylidene-N'-(2-hydroxyethyl) ethylenediamine)Cr(III)] units together with uncoordinated chloride ions. The asymmetric unit contains two crystallographically independent but geometrically similar SalNEdien molecules attached together to the Cr(III) ion. The Cr atom has six nearest neighbors and the coordinate geometry may be described as slightly distorted octahedron. The two tridentate SalNEdien ligands forming almost perpendicular planes at the metal atom (a dihedral angle of 93.4°). The five membered ring equires envelope conformation with asymmetric parameter ΔCs[C9]=8.98° in one molecule, while in another molecule it has half-chair conformation with asymmetric parameter ΔC2[Cr,N1]=8.88°. The uncoordinated chloride ion is involved in an intra and intermolecular hydrogen bonding. In this attempt, it is forming pseudo five membered rings. Additional features of the structure will be presented.

P07.07.002 CRYSTAL AND MOLECULAR STRUCTURE DETERMINATION OF THE BIS(4-METHYL-1-PIPERAZINEGLYOXIMATO) DI PYRIDINATO COBALT(III). CHLORO DINITRATE THREE HYDRATE. S. Öztürk, Department of Physics, Faculty of Arts and Sciences, Erciyes University, Kayseri-38039, TURKEY, and Ş. Işık, Department of Physics, Faculty of Arts and Sciences, Ondokuz Mayıs University, Kurupelit, Samsun-55139, TURKEY, and M. Macit, Department of Chemistry, Faculty of Arts and Sciences, Ondokuz Mayıs University, Kurupelit, Samsun-55139, TURKEY, and H. K. Fun, X-ray Crystallography Unit, School of Physics, Universiti Sains Malaysia, 11800 USM, MALAYSIA.

Recently, since the increasing use of coordination compound in analytical, bio, pigment and medical chemistry, many investigators have studied these topics. Especially vic-dioximes have been widely investigated as analytical reagents 1,2 and models for biological systems 3,4, such as vitamin B1,2 [1-2]. The possibly chelating ligand oxamid-oxime(diaminoglyoxime) recently received new interest when the X-ray structure determinations of them [3-5]. The Co(III) ion in this complexe is a octahedral geometry and the dipyridine rings are in planar and piperazine rings assume chair conformation. In the solid state, the unit of $CoC_{24}H_{36}N_{10}O_4$ with the (NO_3) and Cl ions are linked to form infinite "zigzag" chains along the c-axis. The crystal structure is stabilised by van der Waals interaction also. Crystal Data: $C_{24}H_{36}CoN_{10}O_4.2(NO_3).3(H_2O).Cl$, M_r=801.06, Monoc., Cc (No. 9), a=17.6920(4), b=11.8163(2), c=16.4752(4)Å, γ=91.679(1)°, V= 3442.7(1) $Å^3$, Z=4, T=293(2)K, R=0.0458 for 5254 observed data with $I > 2\sigma I$.

P07.07.003 CONFACIAL BIOCTAHEDRAL DITUNGSTEN III THIOETHER METALLOLIGANDS. Masood Parvez, Vivian J. Mozol & P. Michael Boorman. Department of Chemistry, University of Calgary, Calgary, Alberta, Canada T2N 1N4.

C-S bond cleavage of a μ-thioether in $Cl_3W(\mu\text{-}L)_3WCl_3$ (L = cyclic thioether) leads to species having pendant arms possessing a variety of donor atoms. Successful complexation of these pendant arms to a secondary metal center, could establish a

use for C-S bond cleavage in the construction of site specific metalloligands. As such, the complexes $[PPh_4][Cl_3W(\mu\text{-}L)_2(\mu\text{-}CH_2)_2E(CH_2)_2SC_6H_4(o\text{-}PPh_2)WCl_3]$ (L = tetrahydrothiophene = tht, E = no atoms; L = 1,4-thioxane, E = O; L = pentamethylene sulfide = pms, E = CH_2) were reacted with one equivalent of $AgBF_4$, which resulted in the formation of (1), (2) and (3). The results of the X-ray crystallographic analyses of (1), (2) and (3) will be presented.

(1) Crystal data: $C_{30}H_{38}Cl_6PS_4AgW_2.0.5C_3H_6O.0.5C_4H_{10}O$, FW = 1312.23, orthorhombic, $P2_12_12$, a = 17.150(5) Å, b = 30.28(1) Å, c = 9.012(9) Å, V = 4681(4) Å^3, Z = 4, D_x = 1.86 Mg m^{-3}, λ (Mo Kα) = 0.71069 Å, μ = 5.903 mm^{-1}, T = 200 K, θ_{max} = 25.0°, measured reflections = 4679, observed data [I > 3σ(I)] = 1499, R = 0.053, wR = 0.051.

(2) Crystal data: $C_{30}H_{38}Cl_6O_3PS_4AgW_2.0.5CH_2Cl_2$, FW = 1336.59, monoclinic, $P2_1/c$, a = 9.125(1) Å, b = 18.743(2) Å, c = 25.389(3) Å, β = 99.24(1)°, V = 4285.9(8) Å^3, Z = 4, D_x = 2.07 Mg m^{-3}, λ (Mo Kα) = 0.71069 Å, μ = 6.511 mm^{-1}, T = 170 K, θ_{max} = 27.5°, measured reflections = 7254, observed data [I > 3σ(I)] = 4250, R = 0.092, wR = 0.096.

(3) Crystal data: $C_{33}H_{44}Cl_6PS_4AgW_2.3CHCl_3$, FW = 1646.34, monoclinic, $P2_1/c$, a = 13.553(3) Å, b = 27.799(4) Å, c = 15.931(3) Å, β = 112.10(1)°, V = 5561(2) Å^3, Z = 4, D_x = 1.97 Mg m^{-3}, λ (Mo Kα) = 0.71069 Å, μ = 5.405 mm^{-1}, T = 170 K, θ_{max} = 27.5°, measured reflections = 13670, observed data [I > 3σ(I)] = 5709, R = 0.081, wR = 0.093.

P07.07.004 SYNTHESIS AND CRYSTAL STRUCTURE OF ALKOXO- AND PHENOXO- BRIDGED DINUCLEAR FE(III) COMPLEXES. Tian-Huey Lu,[a] K. Panneerselvam,[a] H. Aneetha[b] and Chung-Sun Chung[b], [a]Department of Physics, [b]Department of Chemistry, National Tsing Hua University, Hsinchu, Taiwan 300, R.O.C.

Synthesis and study of dinuclear complexes with metal ions in close proximity has attracted considerable attention, since homo or heterodinuclear metal centers form the active sites in many enzymes. These bridged complexes are also studied because of their interesting spectral, magnetic and redox properties. The presence of oxo-bridged dinuclear iron centers in several nonheme proteins has resulted in synthesis of several dinuclear Fe(II) and Fe(III) complexes in an effort to model such active sites. These complexes exhibit strong magnetic interactions and extent of magnetic exchange parameter *J* dependence on Fe-O-Fe bridge angle and the geometry at the metal ion. In course of our investigations, we have isolated alkoxy bridged and phenoxy bridged dinuclear Fe(III) complexes. Complex **1**, $[FeL^1]_2$ (L^1=N,N'-bissalicylidene-1,3-diaminopropan-2-ol) crystallizes in P1bar with a=13.880(3), b=15.151(2), c=19.557(2)A, α=94.36(1), β=108.59(1), γ=113.87(1)^o, Z=4, R=0.087, wR^2=0.283 for 8319 reflections with I>2σ(I). There are two molecules in the asymmetric unit. Each molecule consists of two iron(III) centers, which are bridged by two phenolate oxygen atoms. The phenolate oxygen atom bridge is somewhat asymmetrically disposed in molecule A while in molecule B it is highly symmetric. The geometry at the metal ions is distorted octahedral, the other four positions being occupied by two terminal phenolate oxygen atoms and two nitrogen atoms of the ligand. Complex **2**, $[FeL^2]_2$ (L^2=2,6-bis(salicyl ideneaminomethyl)-4-methylphenol) crystallizes in P1bar with a=10.0188(1), b=13.3004(2) c=15.9861(2)A, α=84.622(1), β=82.602(1), γ=80.938(1)^o, Z=2, R=0.072, wR^2=0.214 for 5353 reflections with I>2σ(I). The asymmetric center has two metal ions bridged by two phenoxy oxygen atoms. The geometry at the metal ion is distorted octahedral coordinated by four oxygen atoms in equatorial position and two nitrogen atoms of the Schiff base ligand in axial position.

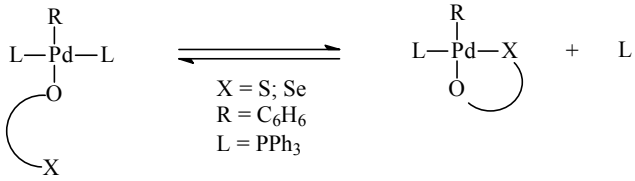
P07.07.005 STRUCTURAL STUDY OF ORGANO-PALLADIUM COMPLEXES. C. Thompson and G.J. Kruger, Dept. of Chemistry and Biochemistry, Rand Afrikaans University, P.O.Box 524, Auckland Park, 2006, SA. and H.G.Raubenheimer, Dept. of Chemistry, Private Bag X1, University of Stellenbosch, Matieland, 7602, SA.

Palladium complexes have been long been known for their catalytic activities (1). An important development in the understanding of catalysts came with the definition by Rauchfuss (2) of the concept of hemilability. This phenomenon involves a monodentate ligand coordinating to the central metal through a second atom to become bidentate, and then disassociating again. The present study furnishes conclusive proof of the hemilability of a series of S^O and Se^O ligands of Pd complexes. These complexes exhibited the following equilibrium in solution:



Crystallisation of these solutions yielded two different crystal morphologies. Characterisation by single crystal x-ray diffraction proved that these crystals showed two different types of molecular structure corresponding to the monodentate and bidentate cases respectively.

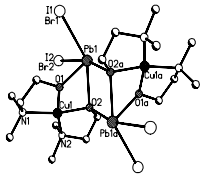
P07.07.006 SYNTHESIS AND CRYSTAL STRUCTURE OF CU(II) COMPLEXES OF DI-N-CYANOETHYLATED TETRAAZA MACROCYCLE. K. Panneerselvam,[a] Tian-Huey Lu,[a] H. Aneetha[b] and Chung-Sun Chung[b], [a]Department of Physics, [a]Department of Chemistry, National Tsing Hua University, Hsinchu, Taiwan 300, R.O.C.

The coordination chemistry of polyaza macrocyles has been a topic of research interest and more recently N-alkylated polyaza macrocycles have attracted considerable attention since complexes of these ligands exhibit properties that are distinctly different from their unsubstituted parent macrocyclic complexes. For example, Cu(II) complex of 1, 4, 8, 11-tetrakis (2-hydroxyethyl) - 1, 4, 8, 11 - tetraazacyclotetradecane shows increased lability in dissociation reactions, whereas Cu(II) complex of 1, 4, 8, 11-tetraazacyclotetradecane is extremely stable. Most of the studies involved complexes of completely N-alkylated tetraaza macrocycles with very few reports on complexes of partially N-alkylated macrocycles. In continuation to our work on synthesis and kinetics of the macrocyclic complexes, here, we report crystal stuctures of partially N-alkylated Cu(II) complexes of C-*rac*- (**1**) and C-*meso*- (**2**) isomers of 1, 8-bis (2-cyanoethyl) 5, 5, 7, 12, 12, 14 - hexamethyl - 1, 4, 8, 11 - tetraazacyclotetradecane. (**1**) violet and (**2**) orange crystals were obtained by slow evaporation of aqueous solution. Crystal data for (**1**): Orthorhombic, Fdd2 with lattice parameters a = 22.1089(9), b = 30.5304(12), c = 8.7632(4)A, Z = 8. The refinement on F^2 converged at R = 0.049, wR^2 = 0.120, S = 1.03 for 2761 reflections with I > 2σ(I). Crystal data for (**2**): Monoclinic, $P2_1/n$

with lattice parameters a = 11.1755(3), b = 10.9103(2), c = 13.1061(2)A, β = 92.961(1)°, Z = 2, R = 0.053, wR^2 = 0.160, S = 1.07 for 2747 reflections with I > 2σ(I).The macrocyclic ligand in complex **1** adapts unstable *trans*-I stereochemistry while in complex **2** it is in stable *trans* –III sterochemistry. In both the complexes the geometry around the metal ion is square planar with maximum distortions in complex **1**. For the conformation of both complexes, the two six-membered rings are in chair and the two five-membered rings are in gauche forms.

We thank the National Science Council, R.O.C., for support under the grants NSC88-2811-M007-0004 and NSC88-2112-M007-013

P07.07.007 I/BR DISORDER IN THE STRUCTURE OF A NOVEL CU/PB MIXED-ANION COMPLEX AT LOW TEMPERATURE. L.A. Kovbasyuk, O.Yu. Vassilyeva, V.N. Kokozay, Dpt of Chemistry, Kyiv Shevchenko University, Volodimirska St. 64, Kyiv 252033, Ukraine, and Paul Raithby, Dpt of Chemistry, Lensfield Road, Cambridge CB2 1EW, U.K.



As part of our continuing research in the rational design of new mixed metal Cu/M (M - Pb, Co, Ni, Mn) compounds by employing zerovalent copper and metal salt as starting materials,[1] a novel Cu/Pb mixed-anion (Br/I) complex containing dimethylaminoethanol (HL) has been prepared. Its exact composition was established from the X-ray crystallographic study at 180(2) K. The compound appeared to be isomorphous with the Cu/Pb iodide $[CuPbI_2L_2]_2$,[2] but possessed substantially shorter Pb - halogen distances (3.153(2) and 3.189(1) for the Br/I compound against 3.1966(9) and 3.2381(8) Å for the pure iodide). The model on which the refinement was based assumed that halide ligands could be treated as 60% I + 40% Br for the first halogen site and 60% Br + 40% I for the second. The refinement converged at R = 0.0480 and wR2 = 0.1172 for 2017 observed ($I > 2\sigma(I)$) reflections, justified this assumption. $[CuPbBrIL_2]_2$ crystallizes in the monoclinic space group $P2_1/c$, with a = 12.316(5), b = 8.380(2), c = 15.312(2) Å, β = 93.94(3) °.

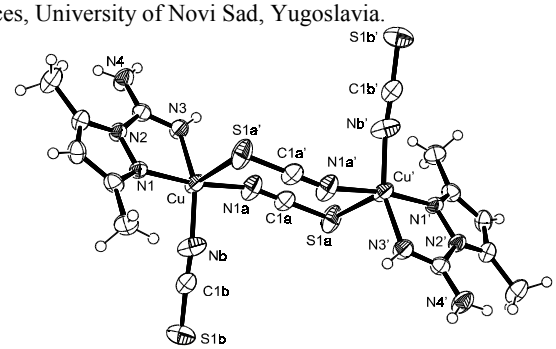
P07.07.008 A SEVEN COORDINATE MOLYBDENUM(II)-DICARBONYL COMPLEX SHOWING A CAPPED OCTAHEDRON GEOMETRY. J. Borge and S. García-Granda, Departamento de Química Física y Analítica, Facultad de Química, Universidad de Oviedo. C/ Julián Clavería, 8. 33006 Oviedo. Spain.

It is well established that molybdenum(II) complexes are typical examples of the seven coordination geometry. Many carbonyl complexes of the type $[MoX_2(CO)_3(L\text{-}L)]$, $[MoX_2(CO)(L\text{-}L)_2]$ and $[MoX_2(CO)_2(L\text{-}L)(\eta^1\text{-}L\text{-}L)]$ (X = halide; L-L = bidentate ligand) have been described and their solid state molecular structures studied by X-ray crystallography. In contrast, cationic complexes of the type $[MoX(CO)_2(L\text{-}L)_2]^+$ are much less known and to the best of our knowledge only the following examples have been described and structurally characterized: $[MoCl(CO)_2(dmpe)_2]^+$ (dmpe = 1,2-bis(dimethylphosphino)ethane), $[MoCl(CO)_2(diars)_2]^+$ (diars = *o*-phenylenebis(dimethylarsine)), $[MI(CO)_2(dmpe)_2]^+$ (M = Mo, W). The coordination chemistry of the bidentate ligand bis(diphenylphosphine) methane (ddpm) has been extensively studied.

In order to study the conformational preference of seven coordinate cationic Mo(II) complexes containing chelating ligands to adopt capped octahedron (C.O.), pentagonal bipyramid (P.B.) or capped trigonal prismatic (C.T.P.) geometries, the synthesis of bromodicarbonyl [bis(diphenylphosphino) methane-κ^2P] molybdenum(II) hexafluorophosphate complex ($C_{52}H_{44}BrF_6MoO_2P_5{\cdot}2CH_2Cl_2$) is described. The complex has been characterized by IR and $^{31}P\{^1H\}$-NMR spectroscopy. The structure has been determined by X-ray diffraction methods. It crystallizes in the monoclinic space group C2/c, Z = 8, a = 42.71(1) Å, b = 11.47(1) Å, c = 26.72(1), and β = 118.58(1)º. The structure determination shows a capped octahedron geometry around the molybdenum atom.

P07.07.009 CRYSTAL STRUCTURE OF $[Cu(NCS)_2(HL)]_2$ (HL=3,5-DIMETHYL-1-CARBOXAMIDE-PYRAZOLE). Z.K. Jacimovic, Faculty of Metallurgy and Technology, University of Montenegro, Yugoslavia, and G.A. Bogdanovic, Institute of Nuclear Sciences "Vinca", Yugoslavia, and A. Spasojevic-de Bire, Ecole Centrale Paris, France, and V.M. Leovac, and E.Z. Iveges Institute of Chemistry, Faculty of Sciences, University of Novi Sad, Yugoslavia.



Hot ethanolic solution of the 3,5-dimethyl-1-carboxamidepyrazolium nitrate ($HL{\cdot}HNO_3$) and $Cu(NO_3)_2$ in mole ratio 2:1, in the presence of NH_4SCN excess forms complex of the formula $[Cu(NCS)_2(HL)]_2$.

Crystal data: triclinic, space group P-1, a=7.181(6)Å, b=8.749(2)Å, c=11.366(3)Å, α=70.30(2)°, β=85.86(5)°, γ=66.98(2)°, V=617.3(6)Å^3, Z=1, μ=2.097 mm^{-1}, Dc=1.713 g/cm^3, CAD-4, MoK$_\alpha$=0,71073,theta-max=27.01.

The structure was solved by direct methods and refined by full matrix least-squares using SHELXL 93 program to a final R=0.046 for 2099 reflections with I>2σI. The complex has a dimeric pentacoordinated structure which is, in addition to the endo-bidentate(N,N)coordination of the pyrazole ligand, formed by both non-bridging(N) and bridging(NS) coordination of the NCS-group. The center of the 8-membered Cu2(NCS)2 ring coincides with a crystallographic inversion center.

P07.07.010 CRYSTAL STRUCTURES OF CIS-$(Et_3NH)[MoCl_4L_2]$ AND TRANS-$(LH)[MoBr_4L_2]$ (L = 4-Ethylpyridine). J.V.Brenčič and B.Modec, Faculty of Chemistry and Chemical Technology, Aškerčeva 5, P.O.B. 537, 1001 Ljubljana, SLOVENIA.

Coordination compounds containing 4-Ethylpyridine ligand are rare. The products of reaction between $(NH_4)_2[MoX_5.H_2O]$(X=Cl,Br) with diluted solutions of 4-Ethylpyridine in organic solvents are several. At room temperature, depending on experimental conditions, ionic compounds containing cis and/or trans-$[MoX_4L_2]^-$(X=Cl,Br;L=4-

Ethylpyridine) were isolated. Single crystals were grown by concentrating acetonitrile solutions of the crude products.

Cis-$(Et_3NH)[MoCl_4L_2]$ is orthorhombic ($Pca2_1$) with a=13.703(1), b=7.766(2) and c=16.793(1)Å. The structure was solved by direct methods and refined to R_1 = 0.029 and wR_2 = 0.0638. Average Mo - Cl and Mo - N (4-Ethylpyridine) bonds are 2.43(1) and 2.20(1)Å. Weak hydrogen bonds exist between the cation and the chlorine atoms of the anion.

Trans- $(LH)[MoBr_4L_2]$ is monoclinic ($P2_1/n$) with a=11.764(2), b=29.059(5), c=15.755(1)Å and β=96.36(1)^0. The structure was solved by direct methods and refined to R_1 = 0.0409 and wR_2 = 0.0918. Mo - Br bonds are from 2.554(1) to 2.602(1)Å, average Mo - N(4-Ethylpyridine) bond is 2.22(1)Å. Trans 4-Ethylpyridine ligands are in eclipsed conformation. Hydrogen bonds between the cation and the bromine atoms of the anion are present.

Mo - halogen and Mo - nitrogen bonds are in the same range as found before in the structures of $(PyH)_2[MoCl_5Py]$ and trans,trans - $[MoX_2Py_4].[MoX_4Py_2]$ (Py = pyridine, C_5H_5N; X = Cl,Br) [1,2]

P07.07.011 SOME EIGHT-COORDINATE COMPLEXES OF EUROPIUM AND GADOLINIUM. T.A. Hamor, C.J. Jones, K. Paxton and R.G. Lawrence, School of Chemistry, University of Birmingham, Birmingham B15 2TT, UK.

We have synthesised a number of complexes [Ln(Tp)X], Ln = trivalent lanthanide, Tp = hydrotris(pyrazol-1-yl)borate, X = diketonate or benzoate, and containing either one or two Tp ligands. The crystal structures of complexes with Ln = Eu or Gd, and X = acetylacetonate, benzoylacetonate, benzene-1,4-dicarboxylate and benzoate have been determined. In every case these were found to be 8-coordinate. Dimeric compounds are formed when X = benzoate. Analysis of interfacial angles [M.G.B. Drew, Coord. Chem. Rev., 1977, 24, 179 - 275] shows that the coordination polyhedra approximate to a greater or lesser extent to standard 8-coordinate dodecahedral (DOD), square antiprismatic (SAP) or bicapped trigonal prismatic (BCTP) geometry. Deviation from ideal geometries, however, is inevitable due to the presence of the rigid tripodal Tp ligand. Results for the structures listed below will be presented, and will be compared with analogous structures, also containing the Tp ligand, determined previously [C. J. Jones et al., J. Chem. Soc. Dalton Trans., 1989, 1393; 1990, 581; 1996, 501; D.L. Reger et al., Inorg. Chem., 1990, 29, 416].

Compound	Coordination Geometry
(1) (benzoylacetonato)bis(Tp)Eu	SAP
(2) (acetylacetonato)bis(Tp)Eu	BCTP
(3) bis[bis(benzoato)(Tp)Eu]	BCTP / DOD *
(4) bis(Tp)Gd(OOCPhCOO)bis(Tp)Gd	SAP
(5) bis[(benzoato)bis(Tp)Eu]	DOD / DOD

* Compound (3) crystallises with two independent dimeric centrosymmetric molecules in the unit cell.

P07.07.012 STRUCTURAL STUDIES OF NOVEL MIXED RUBIDIUM LITHIUM ALKOXIDE CAGES LINKED BY BRIDGING LIGANDS. S. T. Liddle and W. Clegg, Department of Chemistry, University of Newcastle upon Tyne, Newcastle upon Tyne, UK, NE1 7RU, and R. E. Mulvey and A.M. Drummond, Department of Pure and Applied Chemistry, University of Strathclyde, Glasgow, UK, G1 1XL.

Recent times have seen a revival of interest in hetero-alkali metal complexes,[1] and metal alkoxides for use via sol gel processing in electronic and ceramic industries.[2]

Such complexes are principally known for their role in difficult and selective proton abstraction reactions, often succeeding where more conventional alkyl lithium reagents fail.[3]

Two mixed rubidium lithium alkoxide cages are presented and discussed. Modified synthesis generated two alkoxide cages. Both are unprecedented. Indeed the dearth of organorubidium structures was highlighted in a recent review.[4] Bridging tetramethylethylenediamine, an unusual, but not unheard of occurrence, is present in both solid state structures.

Single crystal X-ray crystallography has proved invaluable in structurally characterising these two complexes at 160K. For a sneak preview see *Chem. Commun*., 2391, 1998.

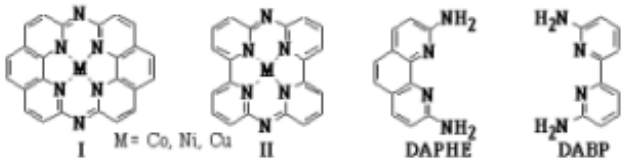
P07.07.013 STRUCTURAL INVESTIGATIONS ON HEXA-AZA-MACROCYCLE PRECURSORS. J.Costamagna, F.Caruso(*), J.Canales and J.Ramirez. Faculty of Chemistry and Biology, Universidad de Santiago, Santiago-33, Chile; (*) : Istituto de Strutturistica Chimica, CNR, Monterotondo Stz., Rome, Italy.

Compounds **I** and **II** has been employed as electro- and photo-catalysts in the synthesis of fuels from the reduction of carbon dioxide[1]. Diamino-phenanthroline (**DAPHE)**, and diamino-bipyridine (**DABP**), are precursors in the synthesis of **I** and **II ,** respectively. Structure determination by single crystal X-ray diffraction has been performed for [Co(**DAPHE**)$(CH_3COO)_2$] and [M(**DABP**)$(CH_3COO)_2$] (M = Ni, Cu).



Crystal data are summarized next.

[Co(**DAPHE**)$(CH_3COO)_2$]: monoclinic, C2/c, a=12.813(6), b=10.218(6), c=13.811(5)Å,β=118.17(2)º, Z=4. R=0.046, wR=0.078, for 1787 reflections.

[Ni(**DABP**)$(CH_3COO)_2$]: monoclinic, $P2_1/n$, a=8.124(5), b=10.343(6), c=18.723(12)Å,β=98.35(2)º, Z=4, R=0.069, wR=0.095, for 2537 reflections.

[Cu(**DABP**)$(CH_3COO)_2$]: triclinic, P-1, a=10.099(5), b=10.257(5), c=8.015(4)Å, α=112.97(2), β=93.13(2), γ=92.96(2)º, Z=2, R==0.076, R=0.098, for 2603 reflections

Distortions from regular octahedron, coordination of acetate and comparison between these structures will be presented and discussed. This work was supported by a grant (Nº 1970354) from Fondecyt.

P07.07.014 CHALCOGENIDE CYANIDE CLUSTERS OF TRANSITION METALS: FROM MOLECULAR COMPLEXES TO EXTENDED SOLID-STATE STRUCTURES. A.V.Virovets, Institute of Inorganic Chemistry SB RAS, Novosibirsk 630090, Russia

Transition metal cyanides form Hoffman clathrates, Prussian Blue type compounds and demonstrate unique properties, structures and chemical reactivity. Recently we have prepared and systematically investigated salts of cyanide cluster anions $[M_4Q_4(CN)_{12}]^{q-}$ (tetrahedral core, M=Mo, W, Re, Q=S, Se, Te, q=4-7) [1] and $[Re_6Q_8(CN)_6]^{4-}$ (octahedral core, Q=S, Se) [2,3].

The tetrahedral anions were found to have the similar structure in the solid state, M-M bond distances of cluster cores being dependent on average oxidation state of M (+4 for Re, +3, +3.25, +3.5 for Mo, W).

Polymeric compounds with a common formula $Cat_xM'_y[Re_6Q_8(CN)_6]_z{*}mH_2O$ ($Cat=H_3O^+$, Cs^+, $(C_nH_{2n+1})_4N^+$, $M'=Mn^{2+}$, Fe^{2+}, Co^{2+}, Ni^{2+}, Cu^{2+}) were prepared for the first time [3]. The structural study has shown that M' atoms are coordinated to N atoms of CN ligands forming polymeric C-N-M'-N-C-Re_6Q_8-C-N-M'... crystal structures. The dimension of polymeric framework depends on the nature of Q and size of Cat^+: 3D polymers for Q=S or Se, $Cat^+=H_3O^+$, Cs^+, Me_4N^+, Et_4N^+, layered structure for Q=S, $Cat=Cs^+$, chains for Q=S, $Cat=Pr_4N^+$. The 3D frameworks contain large cavities filled by Cat^+ and H_2O molecules.

P07.07.015 CRYSTAL STRUCTURE OF THE ORGANOMETALLIC COMPLEX $RuCl_2$(TRIPOD-N)·2.5$CHCl_3$·H_2O. G. Delgado, G. Díaz de Delgado [1], A. Anzellotti, B. Fontal [2], [1] Laboratorio de Cristalografía, Departamento de Química, Facultad de Ciencias, Universidad de Los Andes, Mérida 5101, Venezuela, [2] Laboratorio de Organometálicos, Departamento de Química, Facultad de Ciencias, Universidad de Los Andes, Mérida 5101, Venezuela.

This work presents the crystal X-ray structure determination of the complex cis-dichloro[tris-(diphenylphosphinoethyl)amine] ruthenium(II) chloroform solvate monohydrate.

The compound, of formula $RuCl_2$(TRIPOD-N)·2.5$CHCl_3$·H_2O or ($C_{44.5}H_{44}Cl_{9.5}NOP_3Ru$), was prepared by reaction of $RuCl_2(DMSO)_4$ and TRIPOD-N ligand in toluene solution. Crystals of the complex were obtained by slow evaporation of a chloroform solution of the complex.

The crystal structure is monoclinic, space group P21/c, a= 17.541(3), b= 12.112(1), c= 24.950(3)Å, β= 109.26(1)°, V= 5004.2Å^3, Z= 4, R(F^2)= 0.076, Rw(F^2)= 0.183.

The structure consists of discrete molecules of the complex and solvents held together by normal van der Waals forces. The ruthenium atom is coordinated by two chlorine atoms and one tris-(diphenylphosphinoethyl) amine (TRIPOD-N) ligand, which ocuppies four coordination positions in a facial arrangement. The arrangement around Ru is a distorted octahedron, with P(1)-Ru-P(3)= 95.4(1)°, P(1)-Ru-Cl(2)= 98.8(1)° and P(1)-Ru-Cl(2)= 81.0(1)°. The two chloro atoms are in a cis conformation, as in the parent compound $RuCl_2(DMSO)_4$. The bond distances Ru-Cl(1) and Ru-Cl(2) are 2.488(2) and 2.464(2)Å, larger than 2.413(2) and 2.432(2)Å in $RuCl(DMSO)_4$. Three $CHCl_3$ molecules and one H_2O molecule are included as solvent of crystallization. One of the $CHCl_3$ molecules is disordered.

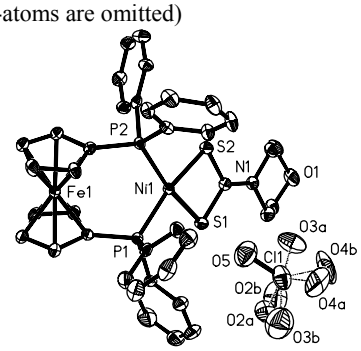
This work was supported by CONICIT, Grant LAB-97000821, for the establishment of the Laboratorio Nacional de Difracción de Rayos-X.

P07.07.016 STRUCTURE OF Ni(II) COMPLEX WITH MORPHOLINEDITHIO-CARBAMATE AND 1,1´-BIS(DIPHENYLPHOSPHINO) FERROCENE. J. Kameníček and R. Pastorek, Dept. of Inorganic and Physical Chemistry, Faculty of Science, Palacký University, 771 47 Olomouc, Czech Republic.

The new compound of composition [Ni(morphdtc)(dppf)]-ClO_4.C_2H_5OH (morph = C_4H_8O, dtc = S_2CN^-, dppf = 1,1´-bis(diphenylphosphino)ferrocene was prepared by reaction of Ni(morphdtc)$_2$, Ni(ClO_4)$_2$ .6H_2O and dppf in boiled ethanol.

Results of X-ray structure analysis: Basic crystallographic data – space group $P2_1/c$, Z = 4; a = 13.108(3), b = 10.280(2), c = 29.839(6) Ĺ, β = 99.34(3)°. The central atom of nickel is coordinated in approximately square planar arrangement (see Fig.) with S_2P_2 chromophore atoms (the deviations from ideal NiS_2P_2-plane are less then 0.05 Ĺ).

Figure. Molecule of [Ni(morphdtc)(dppf)]ClO_4 (solvent and H-atoms are omitted)



The best convergence was reached by assumption of two possible orientation of ClO_4^- group with occupancy factors of three O-atoms equal to 0.5 (R_1 = 0.0376). The details will be discussed at poster.

P07.07.017 STRUCTURE AND STABILITY OF FIVE-COORDINATE ORGANOALUMINUM COMPLEXES. Roman Luboradzki[a], Janusz Lipkowski[a], Janusz Lewinski[b], Piotr Gos[b]; a)Institute of Physical Chemistry, Polish Academy of Sciences, Kasprzaka 44/52, 01-224 Warsaw, Poland b)Department of Chemistry, Warsaw University of Technology, Noakowskiego 3, 00-664 Warsaw, Poland

It has been extensively demonstrated recently that pentacoordination plays a significant role in selective organic transformation mediated by organoaluminum compounds, however, the nature of intermediates are elusive. Structurally characterized five-coordinate aluminum alkyls are dominated by derivatives of macrocyclic or multidentate open-chain ligands, and the fully characterized mononuclear compounds with mono- or bi-dentate ligands, which could serve as a useful structural model, are very scarce. It is apparent from our study that electrophilicity of the metal center and the trans influence of axial substituents are overriding factors determining the structure and stability of five-coordinate aluminum complexes. The respective correlation data will be presented in addition to two novel complexes investigated by using X-ray diffraction method: $Me_2Al(hacet)$*py-Me (**1**) and $MeAl(hacet)_2$ (**2**) (where hacet = deprotonated 2'-hydroxyacetophenone, py-Me = γ-picoline). Compound **1** is the first structurally characterized five-coordinate adduct of dialkylaluminum chelate complex with monodentate Lewis base.

Crystal data of **1:** space group $P2_1/n$; a = 8.615(2), b = 7.499(1), c = 23.746(5) Å, β = 93.12(3)º, V = 1531.8(5) Å^3, Z = 4.

Crystal data of **2:** space group C2/c, a = 12.365(2), b = 10.856(2), c = 11.709(5) Å, β = 95.98(2)º, V = 1563.2(5) Å^3, Z = 4.

P07.07.018 TRITHIOPHOSPHITES – CONFORMATIONAL FLEXIBILITY AND COORDINATION PROPERTIES. O.N. Kataeva, A.T. Gubaidullin, D.B.Krivolapov, I.A. Litvinov, A.E. Arbuzov Institute of Organic and Physical Chemistry, Russian Academy of Sciences, A.E.Arbuzov str., 8, Kazan 420088, RUSSIA

A series of trithiophosphites, as well as their complexes with transition metals has been studied by X-ray single crystal diffraction: $CuHal{\cdot}P(SR)_3$, $CuHal{\cdot}P(SR)_3{\cdot}NCMe$, $CuBr{\cdot}P(SR)_2NRt_2$, $CuSCN{\cdot}P(SR)_3$, $CpMn(CO)_2{\cdot}P(SR)_3$, $MesCr(CO)_2{\cdot}P(SR)_3$ with Hal = Cl, Br, I and R = Me, Et, Pr, i-Pr, Bu, Ph. Depending on the metal center, substituents R at sulfur, the conditions of reactions and crystal growth, different coordination modes have been observed: “classical” monodentate binding via phosphorus, unusual bidentate mode with participation of both P and S donor atoms of the ambident P - S system, as well as both monodentate and bidentate modes in one complex. The metal -phosphorus bond was found to be much stronger and correspondingly shorter than metal - sulfur bond in all complexes. Coordination properties of trithiophosphites were found to be different from those of analogous oxygen and nitrogen containing ligands, phosphites and amidophosphites, which usually exhibit monodentate coordination. The factors determining coordination properties of thiophosphites are considered.

The diversity of coordination modes manifested by trithiophosphites is to a great extent determined by their conformational flexibility due to internal rotation around the P-S bonds. Trithiophosphites retain their flexibility upon complexation. The elongation of the alkyl chain at sulfur results in the increase of the flexibility of thiophosphites and in their conformational inhomogeneity in crystals. The structure of free thiophosphites, including new potential ligands, $P(SR)_3$ with ferrocenyl and cymantrenyl substituents at sulfur, was studied and compared with their structure in coordination compounds. The reasons of conformational changes observed in trithiophosphites after the formation of the coordination bonds are considered.

P07.07.019 CRYSTAL STRUCTURE OF A NOVEL BINUCLEAR COPPER COMPLEX WITH DIACETYLDIOXIME, $Cu_2(C_4H_7N_2O_2)_3(H_2O)(ClO_4)$. S. Lin and S.-X. Liu*, Dept. of Chem., Fuzhou University, Fuzhou 350002, China.

A novel binuclear copper complex with diacetyldioxime, $Cu_2(C_4H_7N_2O_2)_3(H_2O)(ClO_4)$, was prepared and characterized. Deep blue crystals of $Cu_2(C_4H_7N_2O_2)_3(H_2O)(ClO_4)$ are monoclinic, space group P $2_1/n$, a=10.404, b=20.785, c=10.816 Å, β=112.19°, V=2166 Å^3, Z=4.

The structure has some interesting features. The two copper atoms in the title complex molecule have a distorted square pyramidal geometry with the CuN_3O_2 and CuN_2O_3 coordination types, respectively. In the Cu(1) square pyramid, the equatorial plane is defined by the three nitrogen atoms (N(1), N(3), N(4)) and one oxygen atom (O(2)) from the two diacetyldioxime ligands, while the perchlorate oxygen atom being the apical position. However, in the Cu(2) square pyramid, the two oxygen atoms and two nitrogen atoms of the three diacetyldioxime ligands build the base plane, the axial site being occupied by a water molecule. The two copper atoms are bridged in pairs by a oxygen atom and a deprotonated oxime NO group.

It is worth noting that the three diacetyldioxime ligands have different coordination ways in the title complex molecule. The first diacetyldioxime is a bridging bidentate ligand, one oxime is coordinated to two copper atoms (Cu(1) and Cu(2)) through its oxygen atom (O(2)), while the other oxime is coordinated to one copper atom(Cu(1)) through its nitrogen atom(N(1)). The second diacetyldioxime is a bridging tridentate ligand, the nitrogen atom (N(4)) and oxygen atom(O(4)) in one oxime are joined to Cu(1) and Cu(2) atoms, when the nitrogen atom(N(3)) is coordinated to Cu(1) atom. The two oxime nitrogen atoms in the third diacetyldioxime are coordinated to Cu(2) atom. Therefore, the third diacetyldioxime is a chelating ligand.

The authors thank the financial support of the Natural Science Foundation of China. Mrs. S. Lin is leave on from Dept. of Chem., Fujian Teachers' University.

P07.07.020 N-H...O AND C-H...O HYDROGEN BONDS IN4,4'-DIMETHY-6,6'-BIS(MORPHOLINOMETHYL)-2,2'-ETHYLINEDINITRILODIMETHYLIDYNE)MANGANESE(II)DIPERCHLORATE MONOHYDRATE. R. Thirumurugan[a], S. Shanmuga Sundara Raj[b], G. Shanmugam[a] , H . K. Fun. (a) Department of Crystallography andBiophysics, University of Madras, Guindy Campus, Chennai - 600 025, India.(b) X-ray Crystallography Unit, School of Physics, Universiti SainsMalaysia, 11800 USM, Penang, Malaysia.

The main function of defence in mammalian organisms for controlling extracellular and intracellular superoxide radical anions are the Cu , Zn, Mn and Fe containing superoxide dismutase enzymes. A stable non-toxic, low molecular weight mononuclear manganese(II) or (III) complex that catalyses the dismutase in clinical applications with the desirable qualities of low cost, cell permeability and non-immunogenicity. We have attempted to develop manganese based mononuclear complex, because it is a better model compound for metalloenzymes. Many of the manganese(II) and (III) are known to exhibit superoxide dismutase-type activity. In the title compound crystallizes in the triclinic system with space group P-1. The cell parameters: a = 8.9162(1) Å, b = 9.6764(1) Å, c =20.0766(1) Å, α = 78.536(1) °, β = 81.520(1) °, γ = 83.922(1)° , Z = 2. The geometry around the Mn ion is slightly distorted from square planar system. The dihedral angle between the coordination planes [N-Mn-N and O-Mn-O] is 10°. The molecules are stabilized by N-H...O and C-H...O of hydrogen bonds. The structural details will be presented in the poster.

P07.07.021 SHORT HYDROGEN BOND IN ZINC AND POTASSIUM SALTS OF 1,2,4,5-BENZENETETRACARBOXYLIC ACID. R. Diniz, N. G. Fernandes, M. T. C. Sansiviero, Department of Chemistry, Federal University of Minas Gerais, Belo Horizonte, Brazil.

Structures of (I) zinc dihydrogen-1,2,4,5-benzenetetracarboxylate hexahydrate, $C_{10}H_{16}O_{14}Zn$, and (II) potassium trihydrogen-1,2,4,5-benzenetetracarboxylate trihydrate, $C_{10}H_{11}O_{11}K$ have been determinated. Compound(I): Monoclinic, C2/c, Z = 4, μ = 0.86 mm^{-1}, λ(MoKa) = 0.71073 Å, a = 21.948(1) Å, b = 9.760(1) Å, c = 7.291(1) Å, b = 105.51(1)º, V = 1503.7(1) Å^3, R(F^2) = 0.048, wR = 0.108, S = 1.210, 2019 independent observed reflections. Compound(II): Monoclinic, $P2_1/c$, Z = 4, μ = 0.46 mm^{-1}, λ (MoKa) = 0.71073 Å, a = 7.561(1) Å, b = 19.514(1) Å, c = 9.731(1) Å, b = 111.11(1)º, V = 1339.4(2) Å^3, R(F^2) = 0.081, wR = 0.120, S = 2.297, 3085 independent observed reflections. Crystallographic studies show the existence of short hydrogen bond in both compounds. The O...O distances are respectively 2.410(3) Å and 2.389(3)Å. Zinc atom is coordinate to six water molecules. Eight oxygen atoms form the coordination around potassium atom, three from water molecules and five from trihydrogen-1,2,4,5-benzenetetracarboxylate group.

The presence of strong hydrogen bond also was observed in the infrared absorption spectra proper broad envelopes from 1800 to 900 cm^{-1} and band in 795 cm^{-1} observed in acid which

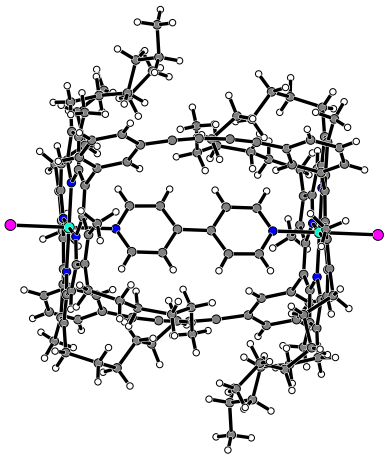
disappear in compound(I) and less relative intensity in compound(II). Raman spectra have broad band of weak intensity in 858 cm^{-1} in compound(I) and 897 cm^{-1} in compound(II) will bee associate short hydrogen bond vibrations. In Raman spectra the region of 1700 to 1400 cm-1 has bands characteristics of a carboxylate group which show difference in the compounds. Compound(I) the separation between symmetric and antisymmetric carboxylate stretching (D) is 142 cm^{-1} which to agree with to ionic compounds. Compound(II) D is 181 cm^{-1}. This D value is intermediate between monodentate and bridging bidentate coordination which to agree to crystallographic data.

P07.07.022 A NOVEL ISOMERISM IN COPPER(I) IODIDE: ETHYLENETHIOUREA (1:2). Chaveng Pakawatchai and Yupa Thanyasirikul, Department of Chemistry, Prince of Songkla University, Hat-Yai, Songkla 90112, Thailand and Brian W. Skelton and Allan H. White, Department of Chemistry, University of Western Australia, Nedlands, WA 6907, Australia.

The 1:2 complex, formed between copper(I) iodide and 'ethylenethiourea', 'etu', $(CH_2NH)_2CS$, has been isolated in two distinct crystalline forms, each corresponding to a distinct isomer. Monomeric $[(etu)_2CuI]$ is monoclinic, $P2_1/m$, a = 7.469(4), b = 14.669(5), c = 11.726(4) Å, β = 101.73(3)°, V = 1258 $Å^3$, Z = 4; final R on $|F|$ for 1353 'observed' (= N_o) (I>3σ(I)) reflections was 0.044. Two independent molecules are found, one half of each comprising the asymmetric unit of the structure, each having a trigonal planar S_2CuI core with crystallographic mirror planes normal to the coordination planes and containing the Cu-I bonds. Cu-I, S are 2.551(2), 2.234(2) (x2)(mol.1); 2.554(2), 2.236(3) Å (x2)(mol.2), with S-Cu-S, I being 116.3(1), 121.82(6) (x2)(mol.1); 117.3(1), 121.27(7)° (x2)(mol.2). Trimeric $[(etu)_2CuI]_3$, monoclinic, $P2_1/n$, a = 12.580(5), b = 16.925(9), c = 17.025(8) Å, β = 96.56(4)°, V = 3601 $Å^3$, Z = 4 trimers; R = 0.059 for N_o = 3278, has one trimer in the asymmetric unit, the three four-coordinate copper atoms being linked into a six-membered Cu_3S_3 ring by alternating bridging etu sulfur atoms, I and the other *S*-etu being terminal ligands. Cu-I,S (terminal) are 2.614(3)-2.637(2), 2.296(5)-2.317(5), with Cu-S (bridging) 2.322(5)-2.384(5) Å. Within the ring, angles at the copper and sulfur atoms are 94.7(2)-107.3(2), 124.8(3)-143.1(2)°.

P07.07.023 THE STRUCTURE OF NOVEL METALLO-PORPHYRINS DETERMINED USING SYNCHROTRON X-RAY RADIATION. N. Feeder, P.R. Raithby, J.K.M. Sanders and S. L. Darling, Department of Chemistry, University of Cambridge, Lensfield Road, Cambridge, CB2 1EW, UK.

The study of Metallo-porphyrins is an exciting and rapidly developing area of chemistry. A knowledge of the structures of these complex molecules is vital to the understanding of their synthesis and catalytic activity. Crystals of these materials, however, are weakly diffracting and contain disordered solvent molecules. Attempts to collect data on these systems using conventional lab sources and diffractometers has failed.



The high intensity X-ray source at the CLRC Daresbury Laboratory has made successful data collections possible using the dedicated Bruker SMART diffractometer. We present the structures of a series of these key molecules.

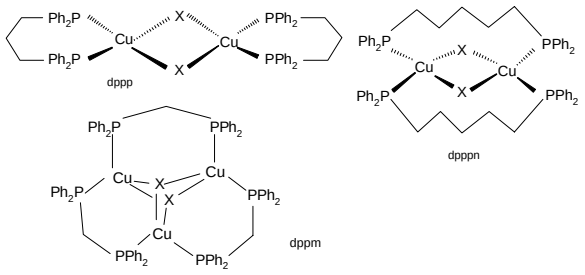
P07.07.024 STRUCTURAL SYSTEMATICS OF 1:1 COPPER(I) HALIDE BIS(DIPHENYLPHOSPHINO)-ALKANE COMPLEXES. Neil Somers, Brian W. Skelton & Allan H. White, Department of Chemistry, The University of Western Australia, Nedlands, 6907, Australia.

Room temperature single crystal x-ray studies of a number of adducts of the copper(I) halide, CuX, (X=Cl, Br, I), with bis(diphenylphosphino)alkane ligands L='dppx', $Ph_2P(CH_2)_nPPh_2$, of intrinsic 1:1 stoichiometry, has been undertaken.

With n=3, (dppp), a μμ'-dihalo bridged dimer, $[LCu(\mu\text{-}X)_2CuL]$, is formed. Each phosphine ligand chelates one copper atom and structures for all X are isomorphous, (Monoclinic, $P2_1/n$, a~10.2, b~18.5, c~13.5Å, β=104.5°).

For n=5, (dpppn) and X=I, the form is also binuclear, but the length of the $(CH_2)_n$ link in each ligand now allows them to bridge both copper atoms. Comparison of the P_2CuI_2 geometry's for n=3 cf. n=5, show Cu-P to be essentially constant, (ca 2.27Å). However, P-Cu-P is enlarged in the n=5 adduct, (ca 118, cf. 103.6°), with I-Cu-I diminished, (ca 97, cf. 109°).

By contrast, for n=1, (dppm) and X=Cl, the familiar array $[Cu_3X_3(dppm)_3]X^-$ with a cation of quasi-3 symmetry is found. The bromide and iodide adducts so far isolated have the linear, non-coordinated $[XCuX]^-$ counterion instead of the simple X^-. Both chloride and bromide adducts are solvated in the lattice with acetonitrile.



P07.07.025 PECULIARITIES OF STRUCTURE OF In(III) AND Sb(III) INTERNAL COMPLEXES WITH 8-HYDROXY-, 8-MERCAPTO- AND 8-HYDROSELENOQUINOLINE. E.Silina, Yu.Bankovsky, L.Pech and J.Ashaks, Institute of Inorganic Chemistry of the Riga Technical University, Latvia, and V.Belsky and A.Stash, L.Karpov Institute of Physical Chemistry, Moscow, 103064, Russia.

Comparison of crystal structures of the III, V and VIII group trivalent metal 8-mercaptoquinolinates [1] has revealed the different regularities of their structure.

In the present work the effect of substitution of the donor atom (O, S, Se) in the ligand on the nature of valence bonds, geometry of the metal atom coordination polyhedron and on conformation of the metal-containing rings has been evaluated on the basis of investigation of crystal structures of $In(C_9H_6NO)_3.C_2H_5OH$ (I), $In(C_9H_6NS)_3.CHCl_3$ (II), $In(C_9H_6NSe)_3$ (III), $Sb(C_9H_6NO)_3$ (IV), $Sb(C_9H_6NS)_3$ (V), $Sb(C_9H_6NSe)_3$ (VI). The significance of the unshared electron pair in the studied antimony complexes has been discussed.

In the investigated complexes, the bidentatic function is characteristic for ligands, and the coordination number of the central atom equals to 6 [3O(S,Se)+3N]. Coordination polyhedra: distorted octahedron (asymmetric isomer in I - III, symmetrical one - in V, VI), strongly distorted pentagonal pyramid - in IV.

Crystal structures of 8-hydroxyquinolinates are characterized by shortening of bonds M – O in the coordination polyhedra of indium and antimony atoms in comparison with the sum of covalent radii. M – N bonds in all studied compounds are weak coordination bonds. In the 8-hydroselenoquinolinate complexes the noticeable inflections of the metal-containing rings are characteristic.

1. E.J.Silina, L.J.Pech, Yu.A.Bankovsky (1998). E.C.M. Abstracts, 18, 1998.

P07.07.026 STRUCTURAL STUDIES OF THE $[M(C_9H_6NSe)_2]$ [M=Pt(II), Cd(II)] COMPLEXES. L.Pech, Yu..Bankovsky, E.Silina and J.Ashaks, Institute of Inorganic Chemistry of the Riga Technical University, Latvia, and V.Belsky and A.Stash, L.Karpov Institute of Physical Chemistry, Moscow, 103064, Russia.

Two new compounds : 8-selenolquinolinates of platinum (I) and cadmium (II) have been synthesised for first time and their full X-ray structural investigation has been carried out. Lattice parameters for: I- a=7.2220(10), b=8.027(2), c=7.876(2)Å, α=79.13(3), β=89.92(3), γ=117.21(3)^o, sp.gr. P-1, Z=1, for II- a=4.0270(10), b=15.663(2), c=12.820(2)Å, β=91.940(10)^o, sp.gr. $P2_1/c$, Z=2.

Complexes I and II have been compared with the previously studied platinum-8-mercaptoquinolinate, 2-methyl-, 2,7-dimethyl-, 2-isopropyl-, 7-methyl-8-mercaptoquinolinate and 2-methyl-5-methylthio-8-hydroxy-quinolinate (III-VIII) and cadmium-2-methyl- and cadmium-2-phenyl-8-mercaptoquinolinate (IX-X). In this paper we repert the structure of complexes of 8-selenol-,8-mercapto- and 8-hydroxyquinoline and their derivatives in order to study dependence of direct donor-acceptor (DA) π -bond formation strength and electron mechanism on the nature of the central (Pt, Cd) and ligand (O,S,Se) atoms [1]. The obtained results of X-ray structure analysis, show that in molecules of square-planar 8-mercaptoquinolinates DA π - bond strength increases in succession Ni<<Pt<Pd . Transition metal ability to form direct DA π -bond increases in the succession of ligand atoms O<<Se<S. Along with increase of direct DA π - bond strength mentioned series the coordination number of central atoms decreases and solubility of chelate compounds in inert organic solvents increases.

P07.07.028 SYNTHESIS AND CRYSTAL STRUCTURES OF $[Me_4N]_2N[CU_2(CS_4)_2]N$ (I) AND $[Me_4N]_4[Cu_4(CS_4)_4]$ (II). Xianglin Jin, Kaluo Tang,Yaoling Long,Youqi Tang, Institute of Physical Chemistry, Peking University, Beijing 100871, P.R. China

The solutions of tetranuclear copper cluster anionic complexes $[Me_4N]_2[Cu_4(SePh)_6]$ or$[Me_4N]_2[Cu_4(SPh)_6]$ in DMF or CH_3CN reacted with CS_2 in the presence of a small amount of S. From the resulting solutions brown block-shaped crystals (I) or orange block-shaped crystals (II) were formed, respectively. Crystal data: (I) Orthorhombic, space group Pbca, a=11.385(4), b=16.683(4), c=10.921(2)Å, V=2074.2(9)Å^3. μ=2.846mm^{-1}, F(000)=1136e, D_c=1.777g/cm^3, for Z=8, R=0.0544 for 1821 observed reflections. (II) Tetragonal, space group P-42(1)c, a=13.952(2), b=13.952(2), c=11.350(2)Å, V=2209.4(6)Å^3. μ=2.677mm^{-1}, F(000)=1136e, Dc=1.671/cm^3, for Z=8, R=0.0645 for 1114 observed reflections. The X-ray crystal structure determination indicated that the molecule of the complex (I) consists of a polymeric anion $[Cu_2(CS_4)_2]_{n-2}$ and cations $[Me_4N]^+$. In the polymeric anion, the repeated unit is a dinuclear copper complex $[Cu_2(CS_4)_2]$-2, which linked to four surrounding aggregations through sulfur bridges to form a two-dimensional layer structure. The Cu-Cu distance is 2.844(2)Å. In the ligand CS_4, the C-S distances average 1.710Å, S-S is 2.049Å. The cations $[Me_4N]^+$ locate between the layers. The molecule of complex (II) consists of a tetranuclear copper cluster anion with four perthiocarbonate ligands $[Cu_4(CS_4)_4]$-4 and four cations $[Me_4N]^+$. The four copper atoms form a tetrahedron, in which Cu-Cu distances average 2.883Å. One of the sulfur atoms in each CS_4 ligand forms the sulfur bridge with Cu atoms while the other is coordinated to only one copper. The C-S distances average 1.706Å, S-S is 2.065Å.

P07.07.029 STRUCTURAL CHRACTERIZATION OF A SERIES OF POLYMERIC AND CHAIN-LIKE Mo(W) CLUSTER COMPOUNDS. Shaofang Lu, Rongmin Yu, Yuchang Liang, Fuxia Sun, Qiangjin Wu, Xiaoying Huang, Jianquan Huang, State Key Laboratory of Structural Chemistry, Fujian Institute of Research on the Structure of Matter, Chinese Academy of Sciences, Fuzhou, Fujian 350002, China

Polymeric and chain-like cluster compounds are expected to exhibit many novel and peculiar electric, magnetic and optical properties on account of their bonding configurations including simullaneous metal-metal and metal-ligand interactions, thus forming a unique electronic structure. Obviously, they are most important potential structure type in the development of new technical materials and therefore have strickingly been attached. Meanwhile, the design of synthetic pathways in terms of the solution reaction remains to be in the ascendant for the structural chemists.

In this paper, the crystal structures of twelve new cluster compounds are systematically described, Their molecular formulas are as follows: (1) $[(WS_4Ag)\cdot Li(DMF)_4]_\infty$ (2). $Mo_2S_4[S_2CN(CH_2CH_2OH)_2]_2$ (3). $W_2S_4[S_2CN(CH_2CH_2OH)_2]_2$ (4). $Mo_2S_2O_2[S_2CN(CH_2CH_2OH)_2]_2$ (5). $[Mo_2S_4(i\text{-}mnt)_2](Et_4N)_2$ (6). $[Mo_2S_4(i\text{-}mnt)_2]_2K(Et_4N)_3$ (7). $[Mo_3S_4(\mu\text{-}SO_3C_6H_4CH_3)(dtp)_3\cdot H_2O]$ (8). $[Mo_3OS_3(HOC_6H_4COO)(dtp)_3\cdot DMF]$ (9). $\{Mo_3[Pb(dtp)_2]OS_3(\mu\text{-}OAc)_2(py)_3(\mu\text{-}O)\}_2$ (10). $\{Mo_3[BiI_3]OS_3(\mu\text{-}OAc)_2(py)_3(\mu\text{-}O)\}_2\cdot 2H_2O$ (11) $[Mo_3(PbI_3)S_4(dtp)_3(C_3H_4N_2)_3][(CH_3)_2CO]]_2$ (12)$[Mo_6(\mu_3\text{-}S)_3(\mu\text{-}S)_3(\mu\text{-}S_2)_3(\mu\text{-}OAc)(dtp)_5]$

All these clusters have a dimeric, polymeric or chain-like packing structures linked by (μ-S), (μ-O), the bridging ligands,

S···S supermolecular interaction or the intermolecular hydrogen bonds. The measurement of the temperature-change specific conductivity reveals that these clusters belong to some kinds of semiconducting crystals. The bond structures of these clusters have also be given in this investigation.

P07.07.030 Cu(II) COMPLEXES OF BIS(PYRIDYL)-PYRAZINE Jorunn Sletten and Hilde Grove, Department of Chemistry, University of Bergen, Allégaten 41, N-5007, Bergen, Norway.

As part of our program of structural and magnetic investigations of di- and polynuclear pyrazine-bridged complexes we have prepared and structurally characterised three new Cu(II) complexes bridged by 2,3-bis(2-pyridyl)pyr-azine; the dinuclear $[Cu_2(dpp)(H_2O)(dmso)Cl_4]\cdot dmso$ (1), and the chain com-pounds $[Cu(dpp)(H_2O)_2]_x(NO_3)_{2x}$ (2) and $[Cu(dpp)(H_2O)_2]_x(BF_4)_{2x}\cdot 2xH_2O$ (3). In 1 one Cu ion is square pyramidal while the other Cu has approximately trigonal bipyramidal environment, the pyrazine nitrogen atoms coordinating equatorially to both metal ions. In 2 the linear chain is extended along a threefold screw axis, Cu has elongated octahedral coordination with pyra-zine nitrogen in the axial positions. In 3 the chain is zig-zag-shaped, the Cu ion has a compressed octahedral coordination geometry, an inverted Jahn-Teller distortion, with pyrazine nitrogen atoms in equatorial positions. Three other dpp-bridged Cu(II) complexes have previously been characterized.[1,2] but only in the present dinuclear complex is the bridging and coordination geometry such that significant magnetic interaction may be expected.

P07.07.031 $RE(HCO_2)_3(HNO_2)(H_2CO_2)$ (RE = Y, Tb, Dy, Ho, Er): SYNTHESIS AND CHARACTERIZATIONS.* J.T. Zhao, G.M. He, Y.T. Xu, B.R. Zeng, S.Y. Mao, J.X. Mi, College of Chemistry and Chemical Engineering,, Xiamen University, Xiamen 361005, China

There are few rare earth based non-linear optical materials. Rare earth formates group show NLO properties [1]. The new title compounds with potential NLO properties were synthesized by solution methods at mild temperature and structures characterized by X-ray methods [2]. Unit cell parameters: Y : 6.664(4), 18.36(2), 8.439(5)Å, 1032.7(9)$Å^3$; Tb : 6.686(2), 18.488(9), 8.472(4)Å, 1047.3(5)$Å^3$; Dy : 6.649(9), 18.43(3), 8.451(9)Å, 1036(2)$Å^3$; Ho : 6.666(2), 18.403(9), 8.446(3)Å, 1036.2(4)$Å^3$; Er : 6.641(2), 18.32(1), 8.427(3)Å, 1025.2(6)$Å^3$. The orthorhombic structure was shown to be a new type with a non-centrosymmetric space group $C222_1$ by single crystal structure determinations. It is characterized by networks of rare earth centered square anti-prisms formed by eight oxygen atoms through bridging carbon and nitrogen atoms. The guest formic acid molecules H_2CO_2 are distributed inside the open tunnels along the crystallographic a-axis and bounded to the network through weak hydrogen bonds. The DTA-TGA measurements show the compounds are stable below 170?g(for Y). The magnetic susceptibility ~ temperature variations show the Curie-Weiss type for the heavy rare earth compounds and the calculated number of Bohr magnetons are 9.6, 11.0, 10.6 and 9.8 for Tb, Dy, Ho and Er respectively and they are consistent with the RE^{3+} ions (9.72, 10.63, 10.60 and 9.59 for Tb, Dy, Ho and Er respectively)[3]. The yttrium compound shows very weak temperature independent paramagnetism.

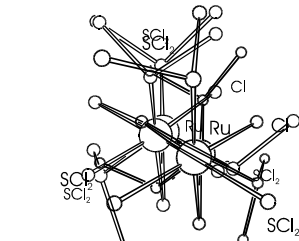
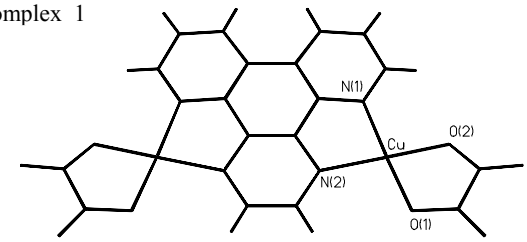
P07.07.032 DINUCLEAR Cu(II) COMPLEXES WITH 4,7-PHENANTHROLINO-5,6:5',6'-PYRAZINE AS BRIDGING LIGAND Hilde Grove and Jorunn Sletten, Department of Chemistry, University of Bergen, N-5007 Bergen, Norway

The first X-ray crystallographic structure determinations of metal complexes of 4,7-phenanthrolino-5,6:5',6'-pyrazine (pap) are hereby reported; the dinuclear pap-bridged Cu(II) complexes $[Cu_2(pap)(ox)_2]\cdot 5H_2O$ (1), $[Cu_2(pap)(H_2O)_7(SO_4)]SO_4\cdot 3H_2O$ (2) and $[Cu_2(pap)(H_2O)_3(NO_3)_3]NO_3$ (3). Crystal data: 1 C2/m, a = 18.369(1) Å, b = 17.6964(7) Å, c = 7.0048(4) Å, β = 102.902(2)º; 2 P-1, a = 7.3457(2) Å, b=13.2214(4) Å, c = 14.5128(3) Å, α = 114.229(1)º, β = 99.134(1)º, γ = 90.252(1)º; 3 $P2_1/n$, a = 8.7376(7) Å, b= 9.0449(8) Å, c = 27.740(2) Å, β = 97.547(1)º. In 1 the copper coordination is square planar; in 2 elongated octahedral, the pap ligand in both com-pounds being essentially parallel to the copper equatorial planes. In 3 the coordination geometry of one copper is square pyramidal while the other is intermediate between square pyramidal and trigonal bipyramidal. Bridging ligands related to pap, like bipyrimidine and pyrazine, have been shown to propagate magnetic interaction between metal centres. The coordination geometries found in the present complexes are favourable for magnetic exchange. Magnetic studies of the compounds will be undertaken.

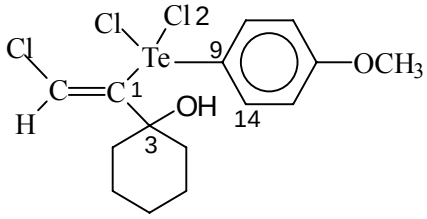


Complex 1



P07.07.033 CONFORMATIONAL POLYMORPHISM OF DICHLORO [(E)-2-CHLORO-1-VINYLCYCLO-HEXANOL](4-METHOXY PHENYL) Te(IV). J. Zukerman-Schpector, R. L. Camillo and I. Caracelli, Laboratório de Cristalografia, Estereodinâmica e Modelagem Molecular, DQ-UFSCar, C. P. 676, 13565-905, São Carlos, SP Brazil and J.V. Comasseto, H. A. Stefani and A. Chieffi, Instituto de Química, Universidade de São Paulo, SP, Brazil

The reaction of aryltellurium halides to acetylenes leading to vinylic tellurides has been reported [1]. After several attempts to get crystals of the title compound, varying the solvent, two different shaped were obtained and the very first determination showed that both unit cells were monoclinic, $P2_1$ /c, having the same volume but different parameters. In both structures the Te^{IV} atom displays a primary disphenoidal geometry, with the chlorine atoms in the apical positions and the C-atoms and the Te lone pair in the equatorial positions.



The main differences between the polymorphs are the torsion angles, given for (I) and (II) respectively: C1-Te-C9-C14: 133.0(6) and -126.0(6)^o , and C1-C3-O-H(O): -118 and 176^o. Regarding the packing the molecules are linked through O-H...Cl interactions, but in (I) a secondary interaction, which inexists in (II), was found, Te...Cl2' 3.837(2) Å, approximately *trans* to C1 [Cl2'...Te-C1 = 160.45(13)^o], giving rise to a distorted octahedral arrangement about Te, with the sixth position vacant.

P07.07.034 MIXED-METAL MACROCYCLES ACTING AS "INVERSE CROWN ETHERS". A.R. Kennedy, R.E. Mulvey and R.B. Rowlings, Department of Pure & Applied Chemistry, University of Strathclyde, Glasgow G1 1XL, UK.

Our interest in modifying the behaviour of *s*-block metal amides by synthesis of heterometallic species containing both group 1 and group 2 metals has led us to a remarkable new structural type [1, 2]. We discovered that rather than being archetypal moisture and oxygen-sensitive compounds these systems react controllably with dry oxygen to form eight membered $[Mg_2M_2N_4]^{2+}$ rings (M = Li or Na, N = hexamethyldisilazane or tetramethylpiperidine) with O^{2-} or O_2^{2-} as guests at the core. These mixed-metal macrocycles are " inverse crown ethers" in a dual sense - the rings are largely metal-based not oxygen-based and the species in the cavities are anions not metal cations.

Recently we have extended these reactions to form larger twelve membered rings $[Mg_2Na_4N_6]^{2+}$ that dideprotonate arene solvents to host $(C_6H_3Me)^{2-}$ and $(C_6H_4)^{2-}$ fragments [3]. A further extension to potassium gives the polymeric species $[Mg_2K_2(O_2)(HMDS)_4]_\infty$ constructed via relatively short K...Me($SiMe_2$) interactions [4].

P07.07.035 A NOVEL HOMOLEPTIC NICKEL THIOLATE WITH A HEXAGONAL–PRISMATIC SULFUR FRAMEWORK. A. H. Mahmoudkhani, Department of Inorganic Chemistry, Göteborg University, SE–412 96 Göteborg, Sweden, and V. Langer, Department of Environmental Inorganic Chemistry, Chalmers University of Technology, SE–412 96 Göteborg, Sweden.

Metal thiolates, including nickel thiolates, are of interest not only due to their rich chemistry and structural diversity, but also as synthetic models, both for the active sites in some biological systems and for metal sulfide catalysis. So far, several polynuclear complexes of nickel thiolates have been synthesized and characterized. In these complexes involving bridged thiolates and approximately planar, rectangular NiS_4 units, there is a strong tendency to form cyclic tetramers, pentamers, hexamers and even higher polynuclear complexes, as well as folded one–dimensional chain fragments. It has been suggested (Henkel & Chen, 1993) that an electronic modification of the thiolate–S atom might be of significant influence on the magnitude of the Ni—S—Ni angle and therefore on the structure of cyclic polynuclear complex. A theoretical study (Alemany & Hoffmann, 1993) on the structure and bonding also revealed that the structural features of nickel thiolates are dominated by Ni—S bonding, while Ni…Ni interactions may destabilize the structure and S…S interactions have minor importance. As a part of our ongoing efforts to elucidate the structural chemistry of these complexes, we have prepared hexakis[di–μ–(trimethylsilylethanethiolato) nickel] and characterized it by single crystal X-ray diffraction analysis. The main building block of this complex, NiS_4 unit, is significantly apart from planar geometry in comparison to other known hexanuclear thiolates. The steric effect of the bulky groups at β-position in thiolate ligands is suggested to be responsible for a tetrahedral distortion of the NiS_4 units in clusters with large rings.

P07.07.036 RUTHENIUM(II)-HALOGENOCOMPLEX-ES STABILIZED BY SCl_2. Ch.Wagner and G.Thiele, Institut für Anorganische Chemie, Universität Freiburg, Alberstr.21a, 79104 Freiburg, Germany

By reaction with sulfur and chlorine Ru-metal forms complexes $RuCl_n(SCl_2)_m$ with SCl_2 ligands [1,2]. In spite of the presence of the strong oxidation agents Cl_2 and SCl_2 Ru(II) complexes as RuS_4Cl_{12} = $[RuCl_3(SCl_2)_3]^-[SCl_3]^+$ or $Ru_2S_6Cl_{16}$ = $[(SCl_2)_2Cl_2Ru(\mu\text{-}Cl)_2Ru(SCl_2)_2Cl_2]$ prevail. SCl_2 is a voluminous ligand with one stereochemical active electrone pair. In consequence the SCl_2-ligands show an interesting stereochemical behaviour , as proofed by structure determination of several SCl_2-complexes. $Ru_2Cl_5(SCl_2)_4$ is a mixed valence binuclear complex $[(SCl_2)_3Ru(\mu\text{-}Cl)_3Ru(SCl_2)Cl_2]$. Its crystal structure contains two different molecules of the same constitution but of different orientation of the SCl_2-ligands (rotamers). This is the first time that in a single crystal structure polymorphic molecules have been found.

Forms of $Ru_2S_4Cl_{13}$ = $[(SCl_2)_3Ru(\mu\text{-}Cl)_3Ru(SCl_2)Cl_2]$ in

two modifications

P07.07.037 ON FORMATION OF MERCURY POLYATOMIC CATIONS. L.M. Volkova, Institute of Chemistry, FE Branch of RAS, Vladivostok 690022, Russia, and S.A. Magarill, Institute of Inorganic Chemistry, Sib Branch of RAS, Novosibirsk 630090, Russia

A distinguishing crystallochemical feature of mercury is the ability to form polyatomic Hg_n cations. A large body of research has not yet recognised all factors contributing to the formation of the Hg_n cations. This work analysed a relationship between the formation of polyatomic cations Hg_n and a change in the number of the Hg atoms, Hg-Hg bond values as well as a dependence of the cation structure on increasing the number of electrons on 6s orbitals of Hg ions. The 5d AO expansion magnitude that increases with the number of 6s electrons and due to relativistic effects was shown to be crucial importance in the formation of Hg_n cations, a regular chance in the number of Hg atoms and Hg-Hg bond values, and the structure of these cations. From the fulfilment of the virial theorem in Hg_n containing compounds we can assumed that with the number of electrons on 6s AO of Hg ions greater then 1, twice decrease in electron kinetic energy will progressively be ahead of the rise in potential gravitation energy of electrons to the nucleus ($2T_e < -V_{Ne}$) owing to relativistic increase in the expansion of 5d AO. It was shown that to fulfil the conditions for state of equilibrium of a system according to the virial theorem, potential energy of the system (compound) may increase as required only through the formation of polyatomic Hg_n cations. The magnitude of the interaction potential energy between mercury ions in the Hg_n cations is determined by the number of the Hg ions, the Hg-Hg bond, and geometry of the cation. A deviation of the Hg_3^{4+} structure from general regularity and a transformation of the close-packed Hg_n layers into the linear chains on heating have been explained on the base of the virial theorem. A steric influence of 5d AO pronounced in elongation of the Hg-Hg bond with the expansion of 5d AO in response to increase in 6s orbital occupation is discussed. It is shown that in the Hg_n cations the Hg-Hg bond elongate with decreasing the possible overflow of 6s electron density from Hg to the ligand at identical average formal charge on the mercury atom.

This work is financially supported by RFBR (Grant 98-05-65223).

P07.07.038 VALENCE TRAPPING PROCESSES IN UNSOL-VATED MIXED VALENCE TRINUCLEAR IRON COMPLEXES. Finn K. Larsen, Claire Wilson, Bo B. Iversen, Marianne L. Hansen, Department of Chemistry, University of Aarhus, DK-8000 Århus C, Denmark, Sergiu P. Palii, Grigore A. Timco, Nicolae V. Gerbeleu, Institute of Chemistry, Academy of Sciences of the Republic Moldova, Acadamei Str. 3, Chisinau, MD-2028, Moldova, Guang Wu, Department of Chemistry, State University of New York, Buffalo, New York 14260-3000, USA.

Intramolecular electron transfer processes in trinuclear mixed-valence compounds of the type $[M_3O(O_2CR)_6L_3]S$ have been the subject of many studies [1]. In particular work has been carried out on trinuclear mixed-valence iron systems, $[Fe^{III}_2Fe^{II}O(O_2CR)_6L_3]\cdot S$, which allow the use of Mössbauer spectroscopy. A number of systems show temperature dependent Mössbauer spectra, changing from a trapped to a detrapped system on raising the temperature. Hendrickson and co-workers have shown that solvate molecules in the crystal can affect the rate of intramolecular electron transfer [2]. Phase transitions have been observed in many systems and it has been suggested that the valence trapping process occurs as an order-disorder phase transition involving the solvate molecules or bulky ligands. However, unsolvated systems undergoing valence trapping have also been reported. It is therefore not always clear that the phase transitions are directly connected to the electron transfer process.

We have measured multi-temperature crystallographic data on two nonsolvated mixed valence complexes $[Fe_3O(O_2CC(CH_3)_3)_6(C_5H_5N)_3]$ and $[Fe_3O(O_2CC(CH_3)_3)_6(C_5H_{10}N)_3]$. Since the complexes differ slightly only in one type of ligand, they provide suitable systems for probing what factors affect the potential energy surface of the Fe_3O core. In both complexes electron transfer mainly takes place between two of the iron sites, while the third site appears trapped at all temperatures. The dynamic behaviour of the systems leads to temperature dependent apparent bond length changes. Presumed Boltzmann distribution over three potential minima allows to estimate potential differences from the bond length distribution.

P07.07.039 Z-SHAPED METALLOMACROCYCLE ISOMER BROUGHT TO LIGHT. Georgina Rosair, James Cameron and Duncan P. Nicol, Department of Chemistry, Heriot-Watt University, Edinburgh, EH14 4AS

The expected saddle conformation for [16] membered Jager-type metallomacrocycles contains a cavity suitable for the binding of small molecules such as dioxygen to the metal centre. The efficacy of such reactions is dependant on cavity geometry and the interactions with the surrounding structure.

Unexpectedly, another isomer was found [1], possessing a previously unseen Z-type conformation. This isomer appears alongside the well-established saddle species in the reaction mixture.

Several by-products were structurally characterised to trace the origin of the Z isomer, one, a tris-bidentate nickel complex has three chemically distinct ligands and another, a polymer, consists of Ni centres linked by diaminopropane ligands.

Conformational and other geometric differences between the saddle and Z isomers were explored, particularly the saturated chelate ring conformation. Using the Cambridge Structural Database, conformations of related rings in [16] membered macrocycles were examined by Principal Component Analysis.

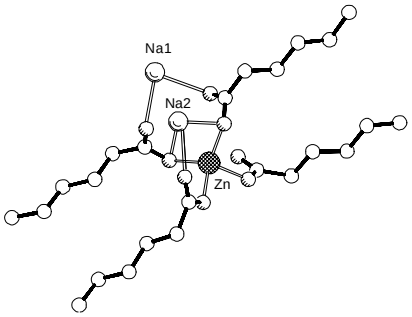
P07.07.040 CRYSTAL STRUCTURE OF SODIUM TETRAHEXANOATOZINCATE. Primož Šegedin, Nina Lah, Gregor Rep, Ljubo Golič and Ivan Leban, Faculty of Chemistry and Chemical Technology, University of Ljubljana, Aškerčeva 5, P.O.B. 537, 1000 Ljubljana, Slovenia.

Thin plate colourless crystals of the title compound were isolated from equimolar solution of zinc hexanoate and sodium hexanoate in 96% ethanol. Each zinc atom is tetrahedrally coordinated by four O atoms from different hexanoate ligands [1.954(2), 1.964(2) Å]. Two crystallographically different sodium ions are six coordinated. Zinc bonded carboxylate oxygen atoms are coordinated to only one sodium ion, whilst the remaining oxygens are coordinated to two sodium ions. Two sets of significantly different C-O bond lengths were observed [1.279(4), 1.233(4) and 1.291(3), 1.235(4) Å].



Crystal data: $C_{24}H_{44}Na_2Zn$, M_r= 571.98, monoclinic, C2/c, $\lambda_{MoK\alpha}$ = 0.71073 Å, Enraf-Nonius CAD-4 diffractometer; a = 37.605(7), b=7.7797(6), c = 10.347(2) Å, ß = 90.82(2)°, V = 3027(1) Å^3, Z = 4, D_{calc}=1.255 g/mL; R_1=0.054 for 2340 observed reflections (I>2σI), wR_2=0.147 for all 3653 reflections, refinement on F^2, 162 parameters (SHELX 97).

P07.07.041 CRYSTAL STRUCTURE OF MOLYBDENUM - RHODIUM SULFIDO CLUSTER CONTAINING $Mo_3Rh(\mu_3\text{-}S)_4$ CUBE. Haruo Akashi,[1] Akiko Nakao,[2] Takashi Shibahara,[3] [1]Research Institute of Natural Sciences, Okayama University of Science, Ridai-cho Okayama, 700-0005 Japan. [2] MAC Science Co., Ltd., Shin-yokohama Kouhoku-ku, Yokohama, 222-0033 Japan. [3] Chemistry Department, Okayama University of Science, Ridai - cho Okayama, 700-0005 Japan.

A novel sulfur bridged molybdenum – rhodium cluster $[Mo_3(\mu_3\text{-}S)_4Cp^*Rh(H_2O)_7(\mu_2\text{-}O)]_4(pts)_{16}\bullet 33H_2O$ (**1**), where Hpts = *p*-toluensulfonic acid, was synthesized by a metal incorporation reaction of $Mo_3S_4^{4+}$(aq) with pentamethylcyclopentadienyl – rhodium (III) chloride dimer $[Cp^*Rh(\mu_2\text{-}Cl)Cl]_2$.

A black crystal of **1** having approximate dimensions 0.4 x 0.35 x 0.3 mm was mounted in a glass capillary. All measurements were performed on MAC Science MXC18 (at 20°C) and DIP 2020 (at –150°C) with graphite monochromated Mo – Kα radiation. Crystal Data: **1** (at 20°C): monoclinic C2/c, a=34.111(8)Å, b=14.539(2)Å, c=25.832(4)Å, β=101.12(2)°, V=12570(3)Å^3, Z=2, R=0.055, R_w=0.065. **1** (at –150°C): triclinic P-1, a=18.3470(3)Å, b=25.772(1)Å, c=27.735(1)Å, α=99.082(1)°, β=105.111(2)°, γ=77.914(2)°, V=12305.8(7)Å^3, Z=2, R=0.051, R_w=0.1457. The structure was solved by and expanded using SHELXS-97 (Sheldrick, 1997). All calculations were performed using the maXus software package of MAC Science Corporation.

The crystal structure of **1** shows a temperature dependence, that is, the crystal system of **1** changes from monoclinic (20°C) to triclinic (–150°C). The structural disorder of pts anions at 20°C disappeared at –150°C.

P07.07.042 CRYSTALLINE COMPLEX $CUL_2(NO_3)_2$ (L=N,N'-DIETHYLETHYLENEDIAMINE) AS A VAPOCHROMIC HOST FOR WATER AND AMMONIA VAPOURS. Beena Narayanan, Discipline of Silicate and Catalysis, Central Salt and Marine Chemicals Research Institute, Bhavnagar 364 002, INDIA Mohan M. Bhadbhade, Physical Chemistry Division, National Chemical Laboratory, Pune 411 008, INDIA

There are increasing research efforts in designing sensor materials for volatile organic compounds and toxic gases. In the course of our studies on thermochromic complexes of Cu(II) and Ni(II) with the ligand N,N-Diethylethylenediamine, red copper complex $CuL_2(NO_3)_2$ which exhibits thermochromic phase transition (red ⇔ blue, 150 ° C) also showed another reversible colour change; the complex changes to blue when exposed to the open atmosphere and comes back to red when heated to 50 °C. This transition was considered as a vapochromic behaviour of the complex due to the adsorption / desorption of water molecules from the atmosphere. Several smaller gaseous entities were tried for the diffusion experiments with the red complex, but only vapours of ammonia changed the color from red to greenish-blue; which upon heating to 65°C gave back the original red complex. The diffusion into the crystalline host system and the reversible binding of these entities forming the fifth coordination with the metal center was established from the single crystal X-ray structures of complexes $[CuL_2(H_2O)](NO_3)_2$ and $[CuL_2(NH_3)](NO_3)_2$. Packing of the molecules in the parent red complex shows sufficient voids for the diffusion to take place. The square planar CuN_4 coordination geometry upon the fifth coordination from water (ammonia) changes to the distorted trigonal bipyramidal environment in both the complexes. Rotation of the ethyl groups and the orientaional changes in the nitrate anions are suggested as a mechanism for the 'vapochromic' transition due to the incoming coordinating species. It is noteworthy that one of the cell axes perpendicular to the chelate rings is constant (~ 8.3 Å) in all the three complexes. As sensing of moisture and ammonia are relevant in the industrial atmosphere, a case study with a simple transition metal complex provides some insight in designing vapochromic host systems.

P07.07.043 NEW COMPLEXES OF RUTHENIUM WITH o-BENZOQUINONEDIIMINE. Venegas-Yazigi D.[$], Mirza H.[b] , Lever A.B.P.[b#], Costamagna J[c]., Latorre R.O., Universidad de Chile, Facultad de Ciencias, Dept. Química, Casilla 653, Santiago, Chile. [$]E-mail: diego@uchile.cl, [b]York University, Dept. of Chemistry, Faculty of Pure and Applied Sciences, 4700 Keele St., Toronto, Ontario, Canada M3J 1P3. [#]E-mail: blever@yorku.ca, [c]Faculty of Chemistry and Bilogy, Universidad de Santiago, Santiago-33, Chile

Questions have been raised with respect to the evaluation of ligand electrochemical parameters [1], when the ligands concerned are themselves redox active, so called "non-innocent" ligands. In order to gain additional information, we have synthesised new complexes of ruthenium with o-benzoquinonediimine (BQDI) and various spectator innocent ligands. In this work, we show the crystal structure and some spectroscopic-structural correlations for the complexes,- $Ru(BQDI)(PPh_3)_2(Cl)_2$, $[Ru(BQDI)(PPh_3)_2(Cl)(MeCN)][PF_6]$, $[Ru(BQDI)(PPh_3)_2(MeCN)_2][PF_6]_2$.

The authors would like to thank Dr. Alan Lough of University of Toronto for X-ray assistance. We would like to thank to FONDECYT Projects 2980026 and 1970354.

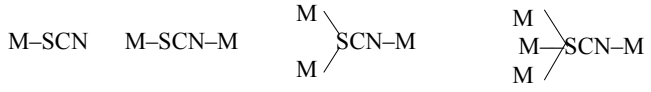
P07.07.044 THIOCYANATOMETALLATES OF COPPER(I) AND SILVER(I). R.Hehl, G.Thiele, Institut für Anorganische Chemie und Materialforschungszentrum FMF der Albert-Ludwigs-Universität, Freiburg. Albertstr. 21, 79104 Freiburg, Germany

In solid state structures of Halogenocuprates(I) and Halogenoargentates(I) a very large number of different polyanionic complexes can be found, due to the co-ordination flexibilty of these d^{10} cations [1]. Especially iodometallates of Ag(I) and Cu(I) exhibit an enormous diversity of their anionic structures as shown by H.Hartl et al. [2].

The application of pseudohalide ligands instead of halides in this context opens up new variation possibilities. Namely the use of the unsymmetrical SCN^- brings in the following options: function as a donor ligand with the "soft" S end

function as a donor ligand with the "hard" N end (together with the convenience of an easy distinction between the two by X-ray analysis)or function as a bridging ligand in various ways.

In the course of our investigations of the synthesis and structure of polynuclear pseudo-halogenocomplexes of d^{10}-metals we have been examining thiocyanato complexes of Ag^+ and Cu^+ [3]. Through variation of the counter ions a wide range of structural motives could be found, showing many different combinations of the possibilities of the co-ordination behaviour of SCN^-.



Structures with large counter ions (e.g. PPN^+) yield isolated thiocyanatometallat complexes where as smaller ones lead to one or two dimensional polymeric structures (e.g. $CsCu(SCN)_2$ and $N(CH_3)Cu(SCN)_2$ resp.). $Ph_4PCu(SCN)_2$ is an example of a compound that exists in both an isolated and a polymeric modification [3,4]. Also three-dimensional polymeric thiocyanatometallates have been synthesised.

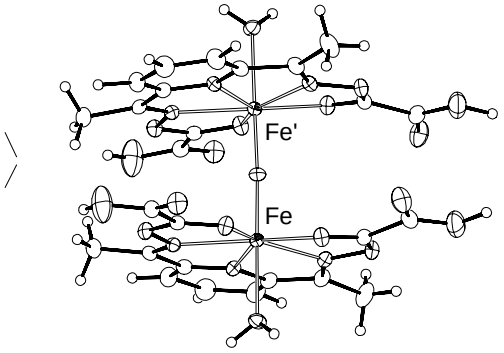
P07.07.045 STRUCTURE OF TWO POLYMERIZABLE CHELATORS DESIGNED FOR REMEDIATION OF HEAVY METALS. Jeffrey R. Deschamps, Judith L. Flippen-Anderson and Clifford George, Naval Research Laboratory, Code 6030, Washington, DC, 20375, USA, Alok Singh, Qin Lu*, and Eddie L. Chang Naval Research Laboratory, Code 6930, Washington, DC, 20375, USA (* GeoCenters, Inc).

Remediation of heavy metals from wastewater requires the selective removal of heavy-metal ions from the waste stream. We are investigating the utilization of metal-ion templating to make ligand-bound polymers that have increased selectivity for the target metal ions. The approach is to create a polymerizable chelator monomer that can be pre-organized by templating with a target metal ion. Templating is followed by reaction with cross-linking agents to lock in the pre-organized chelation coordination. The resulting macroporous polymer is treated before use to remove the metal ions. In this study we examine how the attachment of a linker group to the chelator affects the coordination of the target metal ion with the chelator.

The structures of two polymerizable copper chelates were determined by x-ray diffraction. Data were collected with a SMART-1000 CCD. The coordination geometry of the complexes and the distance between the copper and its ligands were the key features to be studied. Compound 1 (a diamine) crystallized as plates in the space group $P2_1/c$. This compound has a coordination number of 6 (octahedral geometry with a tetragonal distortion). Compound 2 (a triamine) crystallized as rods in the space group $P2_1/n$. This compound has a coordination number of 5 (square pyramidal geometry).

This research was support in part by the Office of Naval Research.

P07.07.046 A NOVEL OXO-BRIDGED DINUCLEAR HEPTA-COORDINATED IRON(III) COMPLEX. A. Bacchi and G. Pelizzi, Dipartimento di Chimica Generale ed Inorganica, Chimica Analitica, Chimica Fisica, University of Parma, Italy , and I. Ivanovic-Burmazovic and K. Andjelkovic, Faculty of Chemistry, University of Belgrade, Yugoslavia



$[Fe(dapoamh)(H_2O)]_2O$

By hydrolysis of paramagnetic $[Fe(Hdapsox)Cl_2]$ [1] (H_2dapsox=2,6-diacetylpyridine bis (oxamic acid hydrazone)), the dinuclear dimeric diamagnetic complex $[Fe(dapoxl)(H_2O)]_2O{\cdot}3H_2O$ [H_2dapoamh=2,6-diacetylpyridine bis (oxalic acid monohydrazone)] is obtained. Complexes of this type may serve as synthons for methemerythrin core models. The ligand coordinates one Fe(III) by a N_3O_2 planar pentadentate system. The metal hepta-coordination geometry is completed to pentagonal bipyramid by one water molecule and one O^{2-} ion. The latter bridges two metals, giving a dinuclear dimeric neutral molecule. In the solid-state the oxo bridge sits on a crystallographic two-fold axis, and, in the dimeric complex, the two symmetry related ligands are on parallel planes and staggered by a rotation of about 140° around the Fe···Fe' direction. The angle Fe-O-Fe' is 177°. The crystal packing is based on strong hydrogen bonds involving the complex and the crystallization waters. Until now only two structures of seven-coordinated dinuclear iron(III) complexes[2] have been observed; one containing a macrocyclic ligand and the other bidentate ligands.

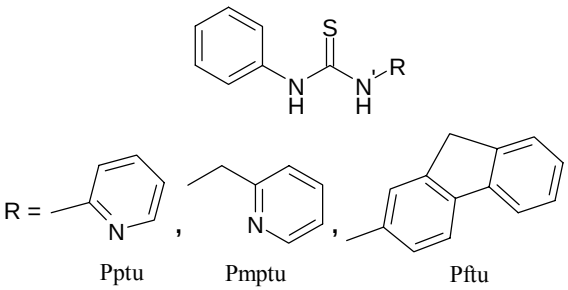
P07.07.047 STRUCTURE OF LUMINESCENT $[AgL(PPh_3)_2NO_3]$ AND $[AgL(PPh_3)_2]NO_3$ (L=THIOUREA DERIVATIVES) COMPOUNDS. G. Pelosi, E. Cavalli, P. Tarasconi and A. Trucco, Department of General and Inorganic Chemistry, Analytical Chemistry, Physical Chemistry, Parco Area delle Scienze, Università di Parma, 43100 Parma, Italy.

The growing interest in molecule-based technologies necessitates the developments of novel materials. Among these, luminescent substances are candidates for photochemical molecular devices, as photosensitizers in electron transfer processes, as luminescent probes for biological applications and for lasers. In this context we have synthesised three ligands (Pptu, Pmptu, Pftu) having a common N-phenylthiourea moiety and different aromatic substituents on nitrogen N'.



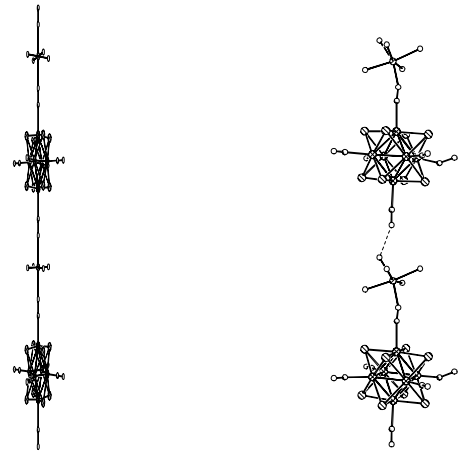
Pptu Pmptu Pftu

These compounds were stoichiometrically reacted with $[Ag(PPh_3)_2NO_3]$ in acetone/acetonitrile(1:1 V/V). The crystals obtained, $[Ag(Pptu)(PPh_3)_2NO_3]$, $[Ag(Pmptu)(PPh_3)_2]NO_3$, $[Ag(Pftu)(PPh_3)_2]NO_3$ were characterised by single crystal X-ray diffraction. The three adducts present different geometries that are related to the donor potentiality of the ligand and to the bulk of the thiourea aromatic substituent. Successively luminescence properties of these compounds were investigated and compared with the analogous Cu(I) complexes both at room temperature and at 10 K.

P07.07.048 A NOVEL METHYLOXOTIN(IV) CLUSTER CONTAINING COCARBOXYLASE. Carmen Taboada, José Sordo, María D. Couce, Agustín Sánchez and José S. Casas, Departamento de Química Inorgánica, Universidad de Santiago de Compostela, 15706 Santiago de Compostela, Spain, E.E. Castellano, Instituto de Física de São Carlos, Universidade de São Paulo, 13560 São Carlos, Brazil and Michael Ruf, Bruker AXS GmbH, P.O. Box D-76181 Karlsruhe, Germany.

The coordination chemistry of vitamin B1 (thiamine, TCl) has been extensively studied during the last twenty years, showing that this vitamin is a very versatile ligand. In spite of that, the interaction of metal ions with cocarboxylase (thiamine diphosphate, H_3CoTCl, the catalytic form of thiamine) is almost unexplored, even though a metal ion participates in the catalytic process in which cocarboxylase is involved. In order to increase the knowledge in this field, and as a part of our work on mixed diorganotin(IV) compounds, we reacted methylphenyltin(IV) dichloride with cocarboxylase in water at pH = 6. The reaction, after elimination of a phenyl group, afforded crystals of the compound {[MeSn(OH)(HCoT)]$_3$O} (OH) . 21 H_20, as was shown by a three-dimensional X-ray analysis. The structure crystallizes in the space group R $\bar{3}$, with a = b = 24.485(3) and c = 27.103(3). Data were collected using a Siemens SMART system equipped with a CCD detector; the model refined to R(F)=0.056 for 3283 reflections with I>2*sigma(I). The trimer displays crystallographic three-fold symmetry; an oxygen atom coordinated to the three Sn cations and an OH anion, both sited on a three-fold symmetry axis, contribute three electrons to the overall balance of charge.

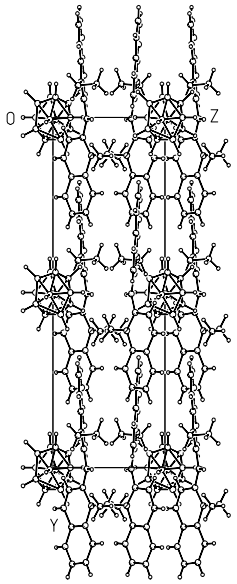
P07.07.049 FACILE TRANSFORMATION FROM ISOLATED FRAGMENTS TO INFINITE CHAINS IN RHENIUM CHALCOCYANIDE CLUSTERS. S.B.Artemkina, N.G.Naumov, A.V.Virovets, V.E.Fedorov, Institute of Inorganic Chemistry SB RAS, Novosibirsk 630090, Russia



Interaction of aqueous solutions of $(n\text{-}Pr_4N)_4[Re_6S_8(CN)_6]$ and manganese nitrate results in formation of crystallohydrates of two structural types. Compound $(Pr_4N)_2Mn[Re_6S_8(CN)_6]\cdot 6H_2O$ (**1**) crystallises in space group $\boldsymbol{P2_12_12_1}$ with cell parameters a=18.286(2), b=18.345(2), c=16.568(2) □, Z=4, and consists fragments $\{Mn(H_2O)_5Re_6S_8(CN)_6\}^{2-}$ linked by hydrogen bonds (left). Compound $(Pr_4N)_2Mn[Re_6S_8(CN)_6]\cdot 4H_2O$ (**2**) crystallises in space group ***I4/m*** with cell parameters a=13.255(2), c=14.432(3) □, Z=2, and consists infinite chains $\{Mn(H_2O)_4Re_6X_8(CN)_6\}^{2-}$ formed by covalent Mn-NC-Re interactions along c axis (right). Structure of **1** may be considered as superstructure of **2**, $\boldsymbol{a_2=a_1+b_1}$, $\boldsymbol{b_2=a_1-b_1}$, $\boldsymbol{c_2=c_1}$. In both structures the cluster anions form face-centred packing motif. In the case of **2** it corresponds with the packing of whole structure in ***I4/m*** space group. But in **1** the arrangement of cations and water is less symmetrical.

Dehydratation of **1** under mild conditions results in loss of two water molecules and formation of **2**, outlining close relationships of structures. This work was supported by RFBR and Program for Support of Young Scientists of Siberian Branch of RAS.

P07.07.050 SUPRAMOLECULAR ASSEMBLY IN THE CHIRAL CRYSTAL STRUCTURE OF THE CYANINE DECAHYDRO-DECABORATE. T.M. Polyanskaya, Institute of Inorganic Chemistry SB RAS, Novosibirsk, 630090 Russia.



Non-centrosymmetric cyanine borates are considerably of interest owing to their potential use as nonlinear optical materials. We have carried out single crystal X-ray analysis of the title compound, $(C_{23}H_{23}N_2)^{+}{}_2\ (B_{10}H_{10})^{2-}$ (1) whose chiral structure is shown below. It is the first example of a supramolecular assembly

with participation of the ions above. The 1,1'-diethyl-2,2'-cyanine dye cation adopts a skewed conformation with approximate symmetry 2 (C_2); the dihedral angle between the roughly planar quinoline rings is 45.8°. The cations are stacked face-to-face by each quinoline ring along [001]. The molecular long axis is elongated along [010]. The overlapping of the quinoline rings is incomplete. In the columns the plane separations are greater than the usual graphite separation of about 3.4 Å because the H atoms of the ethyl groups prevent a closer mutual approach of the quinoline rings. The anions are packed in the gaps between the dye cation columns and are connected by them through close B-H...H-C contacts. The crystal data: the system is monoclinic, space group *C*2, *a*=12.293(1), *b*=22.466(3), *c*=8.1110(6) Å, β=109.35(1)°, *Z*=2, R_I=0.037. The author is grateful to Prof. V.V. Volkov for the disposable single crystals of 1.

P07.07.051 DOES AMMONIUM HEXAFLUORO-NIOBATE (V) EXIST? Frank R. Fronczek, Pamela L. Bryant, Katherine Wu, Youngil Lee, Ae Ja Kim, and Leslie G. Butler, Department of Chemistry, Louisiana State University, Baton Rouge, LA 70803-1804, USA.

Evidence for the existence of the title compound is anecdotal. We obtained samples purported to be "(NH_4) NbF_6" from a prominent commercial supplier, to be used as a tuning standard for MAS and frequency-swept ^{93}Nb solid-state NMR experiments. This compound was expected to contain octahedral Nb, and thus yield simple spectra, but its intriguing NMR behaviour led to additional NMR experiments and variable temperature X-ray crystallography. Crystal structure determinations at 100K and 333K demonstrate that this compound is actually $[NH_4]_5[NbF_4O][NbF_7]_2$, isomorphous with the previously reported Rb salt, $Rb_5[NbF_4O][NbF_7]_2$. The structure is tetragonal, I4cm, and contains both 6-coordinate NbF_4O^- (site symmetry 4) and 7-coordinate NbF_7^{2-} (site symmetry m). The NbF_4O^- moieties have axial Nb...O interactions (2.12(1) Å), forming chains in the **c** direction. Displacement parameters for F atoms of the NbF_7^{2-} moiety are large at 333K, particularly for one F lying on the mirror, which is resolved into off-mirror sites separated by 0.76(2) Å at 100K. Current solid-state NMR interest in the compound lies in its utility as a test sample for experiments designed to observe "invisible" aluminum in zeolites. Here, the NbF_4O^- is easily observed, and serves as an internal reference. The NbF_7^{2-} site is difficult to observe at 303 K, but easy at 333 K. At 100K: a=15.346(3), c=7.800(2) Å, R=0.035; at 333K: a=15.564(1), c=7.8056(4) Å, R=0.026.

P07.07.052 STRUCTURE ANALYSES OF POLYOXO-TUNGSTATES AT SPRING-8 AND BY A NEW IMAGING PLATE DIFFRACTOMETER. Tomoji Ozeki and Yuji Ohashi, Department of Chemistry and Materials Science, Tokyo Institute of Technology, 2-12-1, O-okayama, Meguro-ku, Tokyo 152-8551, Japan

The absorption effect is one of the most severe difficulties in the precise X-ray structure analyses of the crystals containing heavy elements. High energy X-rays from the third generation synchrotrons, *e.g.*, SPring-8, suffer much less absorption and are expected to provide data of high quality. To evaluate this effect, the crystal structure of sodium paradodecatungstate, $Na_{10}[H_2W_{12}O_{42}]\cdot 26H_2O$, was analyzed at the BL02B1 beamline of SPring-8 using monochromatized X-rays with 30.748keV (λ=0.3937Å). The absorption coefficient of the title compound for λ=0.3937Å is 5.25mm^{-1}, while it is 23.2mm^{-1} for the MoK_α radiation. Diffraction data up to $(\sin\theta/\lambda)_{max}$=0.90Å^{-1} were collected by a prototypic cylindrical vacuum camera attached to a Huber 7-axis goniometer. Currently no correction was applied for the absorption effect. However, the structure was refined to the $R(F)$ factor of 0.042 for 14592 reflections with $F_o>4\sigma(F_o)$, which demonstrates the effect of employing high energy X-rays.

To bring our project into the second stage, we designed a new diffractometer, named *DIP LABO*, furnished with an automated imaging-plate reader in cooperation with MAC Science Co., Ltd. The prototypic one used above required manual loading of the imaging plates. *DIP LABO* has a cylindrical imaging plate with the size of 240mm×420mm, covering the 2θ range from –60 to 140º and the ν range of ±45º. It has a κ-type 3-axis goniometer to enable versatile crystal orientation. The automatic data collection procedure utilizes the goniometer to measure all of the independent reciprocal space and invokes the *DENZO* program suite for the data integration and the scaling. It showed satisfactory performance in the preliminary experiments with the sealed tube MoK_α radiation. Now we are planing to place this diffractometer in SPring-8 to enable the automatic rapid data collection with the high energy and high brilliance X-rays.

P07.07.053 STRUCTURES OF METAL DERIVATIVES OF CIS-4-CYCLOHEXENE-1,2-DICARBOXYLIC ACID. B. M. Ramírez, G. Díaz de Delgado and J.E. Contreras, Laboratorio de Cristalografía, and W.O. Velásquez, Laboratorio de Fisicoquímica Orgánica, Departamento de Química, Facultad de Ciencias, Universidad de los Andes, Mérida 5101, Venezuela.

A series of metal complexes of *cis*-4-cyclohexene-1,2-dicarboxylic acid have been prepared in aqueous solutions by mixing stoequiometric quantities of the acid and the corresponding metal carbonate. Crystals were grown by controlled evaporation of the solvent. The complexes were characterized by FTIR and Thermal Analysis (TGA an DSC), and by single crystal X-ray diffraction at 297 K. The coordination of the metal atom, the packing arrangement, and the hydrogen bonding patterns will be presented and discussed in detail. Among the materials studied are: (1) $[Ba(C_8H_8O_4)(OH_2)]\cdot H_2O$: aqua(*cis*-4-cyclohexene-1,2-dicarboxylate) Barium(II), monoclinic, $P2_1/c$, a=12.698(1), b=8.0945(7), c=9.8361(9)Å, β=94.382(2)º, V=1008.03(15)Å^3, Z=4, Dc=2.250gcm^{-3}, R1=0.0345, wR^2=0.0934, S=0.936 for 1445 reflexions I>2σ(I (2) $[Cd(C_8H_9O_4)_2(OH_2)_3]$: triaaquabis(hydrogen *cis*-4-cyclohexene-1,2-dicarboxylate) Cadmium(II), orthorhombic, Pnma, a=12.268(4), b=27.897(8), c=5.513(3)Å, V=1886.8(13)Å^3, Z=4, Dc=1.777 g cm^{-3}, R1=0.0310, wR2=0.0816, S=1.102, for 2207 reflexions with I>2σ(I).

This work was supported by CONICIT, grants S1-95000938 and Lab-97000821, for the establishment of the Laboratorio Nacional de Difracción de Rayos-X, and by CDCHT-ULA, C-727-95-08-A. Part of this work made use of the MRL-UCSB Central Facilities supported by the National Science Foundation under Award No. DMR96-32716.

P07.07.054 CRYSTAL STRUCTURE DETERMINAT-ION OF HEXANEDIAMMONIUM FERRIC TETRACHL-ORIDE, $[C_6H_{12}(NH_3)_2Fe_{(III)}Cl_4]$. I.S.Ahmed Farag, National Research Centre, Physics Dept., Cairo, Egypt, and V.B. Rybakov, Moscow State University, Faculty of Chemistry, Moscow, Russia.

The title compound was prepared by adding $FeCl_2.4H_2O$ solution to an excess hexanediammonium chloride, dissolved in an acidified ethanol water, and then heating for one hour followed by very slow cooling. Prismatic yellowish-brown crystals were obtained with crystallographic data : a = 19.214(4) , b = 19.214(4), c = 14,458(3) Å; V = 5338(2) Å^3 ; the number of formula units = 8 ; the calculated density 1.345 g/cm^3 ; space group I 4_1/ a ; R = 0.0476 , R_w = 0.0541. The intensity data were collected on an Enraf-Nonius CAD-4 computer controlled diffractometer using Mo kα-radiation. The structure was solved by Patterson heavy-atom method and refined by full matrix least-squares using anisotropic temperature factor for all atoms, except

for hydrogen ones, which were treated isotropically. A full discussion was given to describe the structure, which consists of tetra- and hexa-coordinated Fe atoms distributed in layers. These layers are bounded to each other by the organic molecules through three dimensional network of hydrogen bonds and Van der Waals forces. $\alpha\alpha\alpha$ $\alpha\alpha\beta_{\alpha\alpha}$.

P07.07.055 IRON(0) ISOCYANIDE DERIVATIVES. J.F. Gallagher, Dublin City University, Dublin 9, Ireland, N.L. Cromhout, A.R. Manning, University College Dublin, Dublin 4, Ireland, A.J. Lough, University of Toronto, Ont., Canada, M5S 3H6.

We are studying isocyanide derivatives of iron(0) carbonyl phosphite complexes and several will be presented including the following:

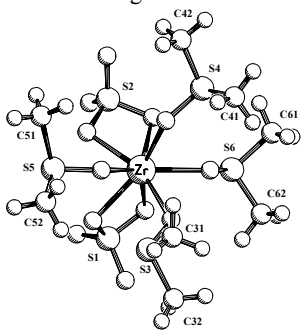
(**1**) $Fe(CO)_2\{P(OPh)_3\}_2$(CN-phenyl), monoclinic, $P2_1/n$, a = 20.7273(5), b = 19.9376(6), c = 21.7240(6) Å, β = 116.863(12)°, V = 8008.7(4) Å^3, Z = 8, T = 150 K, D_x = 1.386 Mg.m^{-3}, R = 0.045 for 8753 reflections > 2σ(I). Compound (**1**) crystallises with two molecules in the asymmetric unit, **A** which is not disordered and a highly disordered molecule **B**.

(**2**) $Fe(CO)_2\{P(OPh)_3\}_2$(CN-*p*-tolyl), monoclinic, *C2/c*, a = 17.6897(10), b = 12.9983(10), c = 17.6460(15) Å, β = 96.079(6)°, V = 4034.6(5) Å^3, Z = 4, D_x = 1.399 Mg.m^{-3}, R = 0.037 for 3760 reflections > 2σ(I). Compound **2** resides about a two-fold axis which contains the iron atom and the tolyl isocyanide ligand.

(**3**) $Fe(CO)_2\{P(OPh)_3\}_2$(CN-mesityl), monoclinic, *C2/c*, a = 19.277(3), b = 13.0802(10), c = 18.251(4) Å, β = 109.697(14)°, V = 4332.6(11) Å^3, Z = 4, D_x = 1.345 Mg.m^{-3}, R = 0.041 for 4972 reflections > 2σ(I). Compound **3** resides about a two-fold axis which contains the iron atom and the mesityl isocyanide ligand.

P07.07.056 CRYSTALLOGRAPHIC STUDY OF DIMETHYL SULFOXIDE COMPLEXES OF ZIRCONIUM SULPHATE. G.J. Kruger, Department of Chemistry and Biochemistry, Rand Afrikaans University, P O Box 524, Auckland Park, Johannesburg 2006, South Africa and H-J. de Jager, Institute of Applied Materials, University of Pretoria, Pretoria 0002, South Africa.

Some of the products which are formed when the oxides of Ti, Zr and Hf are reacted with ammonium sulphate, are soluble in water and can be purified by filtration and recrystallization from various solvents. The preparation and structures of these products are currently under investigation. The complex tetra(dimethyl sulfoxide)zirconium sulphate is one of the adducts that resulted during an attempt to grow single crystals by recrystallization from mixtures of water and dimethyl sulfoxide. The structure of $Zr(SO_4)_2(dmso)_4$ is shown in the figure.



The complex contains a pseudo two-fold axis. It crystallises in the space group Cc with four formula units per monoclinic cell with dimensions a=16.1956(18)Å, b=9.7844(14)Å, c=14.6308(18)Å and beta=104.243(9) degrees.

P07.07.057 REACTION OF [IrCl(diphosphine)]$_2$ WITH NEUTRAL LIGANDS AND THE STRUCTURE OF IrCl(binap)PPh$_3$. T. Yamagata, K. Nakajima, A. Iseki and K. Tani. Department of Chemistry, Graduate School of Engineering Science, Osaka University, Toyonaka, Osaka 560-8531, Japan.

In recent years we have reported the isolation and the structure of the extremely air-sensitive dinuclear complex, $[IrCl\{(R)\text{-binap}\}]_2$[1] (BINAP = 2,2'-bis(diphenylphosphino)-1,1'-binaphthyl) and its unique reactivity toward in methanol and water.[2] In addition, the complex $[IrCl(binap)]_2$ served as an efficient catalyst precursor for asymmetric hydrogenation of prochiral imines.[3] Thus, we have taken a great interest in the reactivity of complexes, $[IrCl(diphosphine)]_2$ (**1**) (diphosphine = BINAP, diphosphine = BPBP: 2,2'-bis(diphenylphosphino)-1,1'-biphenyl) and examined the reaction of **1** with monodentate neutral ligands.

The complex **1** easily reacted with two equivalents of several neutral ligands, L (L = PPh_3, $P(OPh)_3$, etc) at ambient temperature to give the corresponding mononuclear complexes, [IrCl(diphosphine)(L)], in good yield fairly air-stable crystals. The structure of $IrCl\{(R)\text{-binap}\}PPh_3$ (**2**) has been determined by X-ray crystallography.

Crystal Data for **2**: a = 18.579(5), b = 18.579, c = 13.368(6) Å, γ= 120.0º, V = 3996(2) Å^3, trigonal, $P3_1$, Z = 3, μ = 2.684 mm^{-1}, F(000) = 1674, refinement on F^2, R1 = 0.0467, wR2 = 0.1323 for 9687 reflections ($I > 2\sigma(I)$), R1 = 0.0751, wR2 = 0.1470 for 12250 reflections (all data).

P07.07.058 COORDINATION, PACKING ARRANGEMENTS, AND HYDROGEN BONDING PATTERNS IN METAL CITRACONATES AND MESACONATES. G. Díaz de Delgado, A. Briceño, and T. González. Laboratorio de Cristalografía, Departamento de Química, Facultad de Ciencias, Universidad de Los Andes, Mérida, 5101, Venezuela.

The results presented in this contribution are part of a systematic study of the structures of metal derivatives of citraconic (methylmaleic) and mesaconic (methylfumaric) acid. The interest in this type of materials arise from previous observations of dimerization, polymerization, and isomerization reactions in related metal derivatives of unsaturated mono- and dicarboxylic acids.

The metal citraconates and mesaconates studied tend to crystallize as two-dimensional coordination polymers. In some cases, the layers are connected through hydrogen bonds, as in the case of Ba-mesaconate. The two-dimensional nature of the structure of these materials favors a parallel disposition of the potentially reactive double bonds, which could make them reactive in the solid state. For example, in Ba-mesaconate there is an infinite chain of contacts of 4.168 Å between double bonds of neighboring molecules related by translation.

The geometric disposition of the potentially reactive double bonds, the coordination environment of the metal atoms and the carboxylate groups, as well as the hydrogen bond patterns will be presented and discussed in detail.

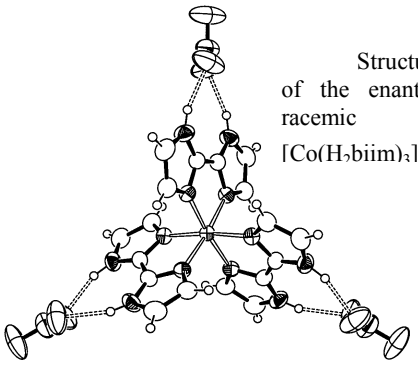
P07.07.059 THE CRYSTAL STRUCTURE OF $[Co(H_2biim)_3][NO_3]_3$. S. Borg, D. Karlsson and L. Öhrström, Department of Inorganic Chemistry, Chalmers University of Technology, SE-412 96 Göteborg, Sweden

The preparation of structures with predefined properties by assembling discrete molecular units is a fast developing area in synthetic chemistry. 1-, 2- and 3-dimensional networks can be created by using transition metal complexes with bis-chelating ligands or ligands that can form hydrogen bonds. These building blocks can be joined by other metal ions, organic molecules or other complex ions.

$[Co(H_2biim)_3][NO_3]_3$ (H_2biim = 2,2′-biimidazole) is an example of a transition metal complex with capacity for both metal coordination and hydrogen bonding. The structure of racemic $[Co(H_2biim)_3][NO_3]_3$ has been determined by single crystal X-ray diffraction. It consists of Co(III) centers hexacoordinated by three H_2biim ligands in an octahedral arrangement. Each H_2biim ligand is hydrogen bonded to one nitrate ion. It is worthwhile noting that in most crystal structure determinations with biimidazole ligands it is the mono- or di-deprotonated form that is present.



Structure of one of the enantiomers of racemic $[Co(H_2biim)_3][NO_3]_3$.

P07.07.060 COORDINATION CHEMISTRY: BIS-BIDENTATE NiN_2X_2 COMPLEXES, H-BONDING IN V(V) COMPLEXES, & Li- AND H-BONDING TO $-CF_3$. Oren P. Anderson, Sean S. Amin, Thomas Barbarich, Agnete la Cour, Debbie C. Crans, Subodh K. Dutta, Anastasios D. Keramidas, Mohammad Mahroof-Tahir, Susie M. Miller, & Steven H. Strauss, Department of Chemistry, Colorado State University, Fort Collins, Colorado 80523, USA; Alan Hazell, Department of Chemistry, Aarhus University, Århus, Denmark; Lothar Hennig, Department of Chemistry, Leipzig University, Leipzig, Germany.

We have investigated the spin state in non-coordinating solvent of similarly substituted bis-bidentate four-coordinate nickel(II)N_2X_2 complexes and of their Lewis acidity in coordinating solvent by ^1H NMR and electronic spectroscopy. The N_2S_2 aza complexes are low-spin in solution, the N_2S_2 Schiff-base and the N_2O_2 aza complexes are in spin equilibrium, and the N_2O_2 Schiff-base complexes are high spin. We present here the crystal structures of selected ligands and of their corresponding four-coordinate (X = S) or six-coordinate (X = O) nickel(II) complexes.

Hydrogen bonding patterns between oxovanadium(V) complexes were investigated in an attempt to discover a hydrogen-bonded dimeric mode of binding for LV(O)(OH) that would be analogous to the dimeric hydrogen bonding commonly found for carboxylic acids RC(O)OH. Among the diverse intercomplex hydrogen bonding patterns studied, the closest example of this analogous dimeric hydrogen bonding was found for the complexes [VO(Hhnbide)(OR)] (R = Me, Et).

Lithium salts of fluoroalkoxo-aluminate anions of the types $Li^+Al(OCR(CF_3)_2)_4^-$, $Li^+AlR(OCR(CF_3)_2)_3^-$, and $Li^+AlF(OCR(CF_3)_2)_3^-$ (R = alkyl, fluoroalkyl, aryl, or fluoroaryl) containing 3–6 Li–F(C) bonds were studied. Significant lengthening of C–F(Li) bonds and significant shortening of the other C–F bonds in a CF_3 group interacting with Li^+ ion was observed. In highly fluorinated alcohols of the type $HO(Ar_f)(CF_3)_2$, O–H···F–C hydrogen bonding can be linear and can slow the rotation of the CF_3 group so that separate ^{19}F NMR resonances are observed.

P07.07.061 STRUCTURAL AND MAGNETIC PROPERTIES OF NEW ORGANOMETALLIC VANADIUM COMPOUNDS. Ramos Silva, M., Paixão, J. A., Matos Beja, A. Alte da Veiga, L. Departamento de Física, Universidade de Coimbra, 3000 COIMBRA, Portugal

The aim of this study was to prepare compounds where there was formation of magnetic entities or isolated magnetic chains. Two hexafluoro-vanadium compounds have been prepared and their structural and magnetic properties investigated. One of these, diphenylguanidinium hexafluorovanadate, crystallizes in a monoclinic structure with space group C2/c. The vanadium atoms lie in a special position of –1 symmetry. The conformation of the cation ($C_{13}N_3H_{14}$) is such that the two phenyl rings are both oriented *anti* to the unsubstituted N atom (other conformations of this ion have been reported [1], [2]). An hydrogen bonding system stabilizes the structure linking each diphenylguanidinium ion with two different VF_6 ions.

The other compound, argininium hexafluorovanadate, crystallizes in a monoclinic structure with $P2_1$ space group . In the assymetric unit cell there are three argininium ions, one hexafluorovanadium ion, and three water molecules. Two of the argininium ions ($C_6H_{14}N_4O_2$) have closely similar conformations while the other is slightly disordered. The crystal packing is stabilized by an extensive three-dimensional network of hydrogen bonds.

Magnetization measurements results will be presented.

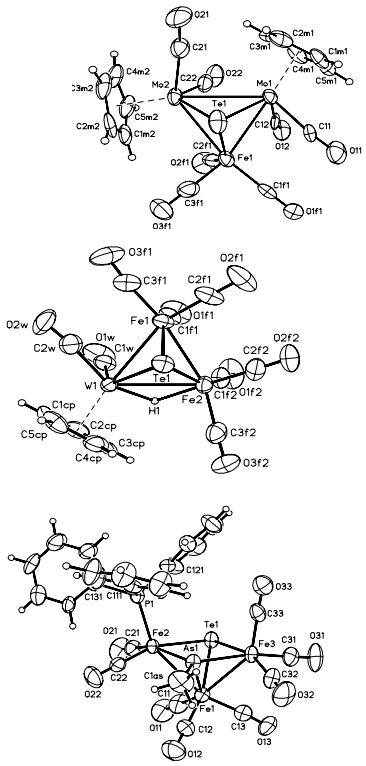
P07.07.062 CHALCOGENIDE CLUSTERS $H_2Fe_3X(CO)_9$ (X = Se, Te) AND THEIR HETERONUCLEAR DERIVATIVES: SOME STRUCTURAL FEATURES. S.N. Konchenko, A.V.Virovets and N.V.Podberezskaya, Institute of Inorganic Chemistry SB RAS, Novosibirsk 630090, Russia.

It has been shown that the chalcogenide carbonyl clusters $H_2Fe_3X(CO)_9$ (X = Se, Te) are the useful starting reagents for the synthesis of heteronuclear derivatives through the addition of another vertex to the cluster core or through the isolobal substitution of organometallic fragments. The number of the Co, Mo, W-substituted compounds and the compounds containing both 16 and 15 groups elements have been obtained by these methods. The examples of the structures determined are represented in the figures:



Some interesting structural features have been found: all the molecule are non-symmetric in the crystalline state; the structures of all telluride compounds significantly differ from their selenide analogs; the coordination number of Te in $FeMo_2Te(CO)_7Cp_2$ is 7 due to the short contacts with C and O atoms of carbonyl ligands, etc. (see [1,2] and literature cited therein).

P07.07.063 STRUCTURE OF POLYNUCLEAR HYDROXOCOMPLEXES OF PALLADIUM (II). E.M.Moroz, S.Yu.Troitskii, S.V.Bogdanov, V.A.Likholobov. Boreskov Institute of catalysis, 630090, Novosibirsk, Russia

We have studied how the polynuclear hydroxokomplexes of palladium(II) (PHC) absorb on carbon materials. We have found that PHC do not change their chemical composition when sorb from their aqueous solutions.

The X-ray RED (radial electronic density distribution) method shows that initial PHC consists of clusters (<10 Å), where metal-metal distances are typical for the chain fragments of PdO structure. As PHC adsorb on carbon materials at room temperature or as the PHC suspension is dried in air at 400 ^{0}C, the bulk particles of PdO structure start to form. The size of PdO particles obtained via adsorption is 15 Å, while that of the particles obtained via drying without carbon support is 25 Å.

We have also obtained the atomic resolution TEM images of sorbed PHC. Simulating the images and using the crystal structure models we have shown that the final product of sorbed PHC drying represents PdO particles containing 100 Pd atoms each. At the high degrees of support surface coverage the PHC particles can grow as complexes of low nuclearity migrate over the surface.

P07.07.064 NITROSYL COMPLEXES OF RHENIUM. T.J. Bartczak and W. Czurak, X-Ray Crystallography Laboratory, Institute of Ecological and General Chemistry, Technical University of Lodz, 90-924 Lodz, Poland, and J.O. Dziegielewski[†], A. Jankowska[†], B. Machura,[†], J. Kusz[‡] and J. Warczewski[‡], Department of Inorganic and Radiation Chemistry[†], Institute of Physics[‡], Silesian University, 40-006 Katowice, Poland.

More than ten new rhenium nitrosyl, six-coordinate complexes of general formula $[ReX_3(NO)(L_2)]$ (where X = Cl or Br, L = PPh_3 or $OPPh_3$) have been prepared via new synthetic routes and characterised by X-ray crystallo-graphy, IR, UV-Vis, ^{31}P NMR and magnetochemical measurements. All complexes can be considered as derived formally from $[ReCl_4(PPh_3)_2]$ [1] by substitution of Cl for Br and NO group and PPh_3 for $OPPh_3$ in some cases. The $[ReBr_3(NO)(PPh_3)]$ complex (I) crystallises in the monoclinic space group C2/c, with Z = 4 and a = 24.621(2), b = 9.570(1), c = 16.005(1) Å, β = 116.96(1)^o; the $ReBr_3(NO)(OPPh_3)]$ complex (II) crystallises also in C2/c, with Z = 4 and a = 14.087(1), b = 13.232(1), c = 19.739(2) Å, β = 96.04(1)^o. The complexes (I) and (II) are isostructural with their chloride counterparts: $[ReCl_3(NO)(PPh_3)_2]$ (III) [2] and $[ReCl_3(NO)(OPPh_3)_2]$ (IV) [3]. The $[ReCl_2(CO)(NO)(PPh_3)_2]$ (V) [2] is also isostructural with (I) and (III).This complex has been prepared by simpler two-stage synthesis:

- $[ReOCl_3(PPh_3)_2] \rightarrow [ReCl_3(NO)(OPPh_3)(PPh_3)]$
  $\rightarrow [ReCl_2(CO)(NO)(PPh_3)]$

instead of a five-stage process described before. The metal coordination is distorted octahedral in all complexes with a linear Re—N—O system.

This work was financially supported by the Polish State Committee for Scientific Research (contract N^o PB 1218/T09/97/12).

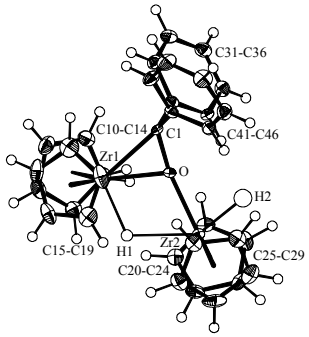
P07.07.065 STRUCTURAL PROPERTIES OF NEUTRAL AND CATIONIC (η^2DIARYLKETONE)-(HYDRIDO)ZIRCONOCENE COMPLEXES. R. Fröhlich, U. Blaschke, and G. Erker, Organisch-Chemisches Institut der Universität Münster, Corrensstraße 40, D-48149 Münster, Germany , and M. Nissinen, and E. Wegelius, University Jyväskylä, Department of Chemistry, P.O.Box 35, FIN-40351 Jyväskylä, Finland.

The (η^2-diarylketone) zirconocene $[Cp_2Zr(OCAryl_2)]_2$ dimers react with group 4 metallocene dihyride complexes $^RCp_2MH_2$ yielding dimetallic compounds [1]. Main structural feature of this dimetallabicyclic framework is the bridging of the two metal centers by the η^2-diarylketone ligand oxygen atom and a μ-hydride ligand. The remaining hydride ligand ist trans-oriented to the μ-H moiety of the $^RCp_2M$ unit. Variations of the metal (Zr, Hf), the aryl part (phenyl, p-tolyl), and ^RCp ligands (Cp, MeCp) lead to several compounds, three of them were characterized by X-ray diffraction. In most cases the hydrogen atoms could be located from Difference Fourier maps.



Treatment of this complexes with $B(C_6F_5)_3$ lead to selective abstraction of the terminal hydride atom and the formation of the corresponding cationic compounds, again a dimetallabicyclic framework with the same bridging of the metals.

Details of the analyses and a comparison of the structures will be presented.

P07.07.066 CRYSTAL STRUCTURE OF $(Ph)_2NCH_2P(Ph)_2$ AND $[(Ph)_2NCH_2P(Ph)_2]_2AgCl$. Ju-Chun Wang, J. Y. Chen and Tai-Chiun Keng, Department of Chemistry, Soochow University, Taipei, Taiwan, 111, ROC.

Compound $(Ph)_2NCH_2P(Ph)_2$ (1) abbreviated as PCN, crystallized in a P1 chiral space group. Four phenyl-rings on the molecule are the major contribution to the crystal packing. Thus, three central atoms P,C and N, are packed disordered. The site occupancy factor for these three atoms is 60% for P1C1N1 and 40% for P2C2N2. Due to this disorder, the P-C (central C-atom) and N-C (central C-atom) distances are constrained to 1.80(2)Å and 1.540(1)Å, respectively. Compound $[(Ph)_2NCH_2P(Ph)_2]_2AgCl$ (2) is formed by the reaction of PCN with AgCl in a two to one mole ratio. Both two PCN ligands use their P-atom to coordinate to the Ag metal ion and leave their N-atom free. The coordination geometry about Ag is close to a trigonal planar with the Ag-P distances of 2.419(1) and 2.448(1)Å and the Ag-Cl distance of 2.507(1)Å. The largest deviation from the plane formed by Ag-Cl-P1-P2 is 0.01Å. Due to the large steric effect of the organic ligand, the P-Cu-P angle is 135.36(3)° that is about 15° larger than the normal 120°.
Crystal data: (1), a=5.7290(6), b=8.8486(10), c=10.3876(12)Å, α=73.601(2) β=81.788(2), γ=89.312(2)°, V=499.76(10)Å^3, triclinic, P1, R1=0.0512; (2), a=17.946(2), b=11.451(2), c=22.036(2)Å, β=106.780(7)°, V=4335.6(9)Å^3, monoclinic, $P2_1/c$, R1=0.0383.

P07.07.067 PRECURSOR OF A POTENTIAL X-RAY CONTRAST AGENT, $C_{39}H_{51}BiO_9$. M.S.Løiten, H. Stener, B. Fjærtoft, School of Pharmacy, Department of Medicinal Chemistry, University of Oslo, Norway

As the main contrast parameter in X-ray imaging is electron density, heavy atoms are essential in potential contrast agents. Soft tissue gives low contrast effect relative to the surrounding organs and a contrast agent is often nessesary to improve the images to give the correct diagnosis.

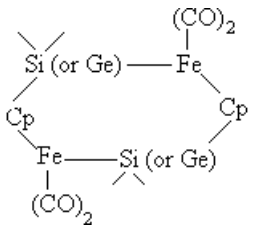
As a part of our work on pharmaceuticals for medial imaging and precursors thereof, we here present one such compound.

The structure of tris-[2-(2,2-dimethyl-1,3-dioxolane-4-(methoxymethyl)-phenyl]bismuth, $C_{39}H_{51}BiO_9$, Mw = 872.78 g mol-1 has been determined by single crystal X-ray diffraction at 150 K. The compound crystallizes in a trigonal space group, no. 148, Z = 6. R = 0.0432 for 7616 unique reflections.

The compound has three chiral carbon atoms. The crystal structure has a trigonal symmetry, with one third of the molecule (i.e. one of the three 1,3-dioxolane substituted side chains and the phenyl ring) in the asymmetic unit and bismuth in a special position. The aromatic rings from two molecules are inclined at 90°, the shortest distance being 3.5 Å between the rings. Hydrophilic parts in the molecules pack against each other. The five-membered 1,3-dioxolane ring has an envelope conformation. Bi is surrounded by 3 + 3 oxygen atoms at 2.276(2) Å and 2.998(2) Å.

P07.07.068 STRUCTURE CHARACTERISTICS OF SIX ORGANOMETALLIC COMPOUNDS CONTAINING SI AND FE. Yao Xinkan and Wang Honggen, Central Laboratory, Nankai University, Tianjin, 300071, China, and Zhou Xiuzhong, Chemistry Department, Nankai University, Tianjin, 300071, China.

The crystal and molecular structures of six compounds containing both of dimethylsilyl(dimethylgermyl) and dicarbonyliron were determined. The skeleton structure formula of these compounds follows (Cp = tert.-butylcyclopentadienyl or tetramethylcyclopentadinyl or indenyl or tetrahydroindenyl)



The distances between Fe atom and five C atoms of the cyclopentadinyl of Cp for these six compounds are in the range of 2.106~2.125 Å. So it can be seen that the π-bonding formed by Fe and five C atoms of the cyclopentadinyl of the Cp is the rigid part of the whole molecule, no matter that the Fe is bonded to Si or to Ge, and no matter what the Cp is.

Some of the least-squares planes formed by two Fe atoms and two Si (or Ge) atoms are the crystallographic planes, and some of them are not (the deviations from the plane are in the range of 0.1~0.4Å), even if the same molecules exist in one crystal. The dihedral angles between this plane and the five-member ring plane included in Cp is various, from 45.9° until 118.5° .It seems that the different Cp has an important influence on conformations of this kind of molecules, and yet any regularity was not been found out.

As long as the Cp was the same, the dihedral angle value between two five-member ring planes included in one molecule was the same, no matter that the molecule was composed of Fe-Si or Fe-Ge.

When Cp was different, the bond lengths of Fe-Si were not changed obviously, but the bond lengths of Fe-Ge were changed quite obviously.

All the non-bond distances Fe-Si, Fe-Ge, Fe-Fe, Si-Si, and Ge-Ge in molecules were changed obviously owing to the different Cp, thus the flexibility of this kind of compounds emerged.

P07.07.069 $(C_8H_{12}N)_2CuCl_4$: FIRST EXAMPLE OF A PLANAR $CuCl_4^{2-}$ ION IN THE ABSENCE OF STRONG HYDROGEN BONDING. Marcus R. Bond and Michael L. Rodgers, Department of Chemistry, Southeast Missouri State University, Cape Girardeau, MO 63701; Carl J. Carrano, Department of Chemistry, Southeast Missouri State University, San Marcos, TX 78666.

$CuCl_4^{2-}$ exhibits coordination geometries, ranging from distorted tetrahedral to square planar, that are matched by a corresponding range of colors, from orange to dark green. Tetrahedral geometry generally occurs in the presence of weak

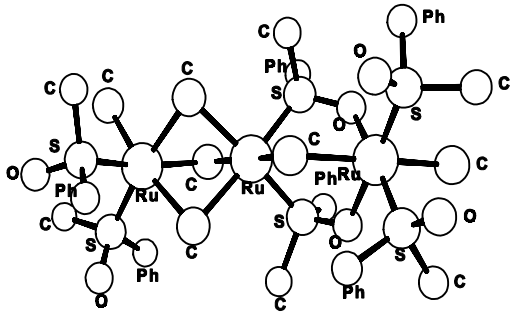
hydrogen-bonding cations (such as quaternary ammonium ions); square planar geometry has, until now, been found only in the presence of strong hydrogen-bonding cations.

The title compound crystallizes by slow evaporation as large emerald green blocks from concentrated HCl solution containing stoichiometric amounts of 1,2,3-trimethylpyridinium chloride and copper(II) chloride dihydrate. A crystal structure determination with complementary spectroscopic measurements confirms the presence of square planar $CuCl_4^{2-}$ that was first indicated by the color. This geometry is achieved, surprisingly enough, in the presence of a quaternary pyridinium cation that should be incapable of strong hydrogen-bonding. The square planar geometry in this case appears to provide optimal packing of the anionic metal complex with the planar cation and suggests that packing forces must also play a major role in determining $CuCl_4^{2-}$ geometry.

Crystal data: Monoclinic C2/c, a=13.380(5)Å, b=9.285(2)Å, c=8.769(2)Å, β=116.83(3)°, V=972.1(6)Å^3, *Z*=2, 716 reflections collected (553 unique, observed), least-squares refinement of 89 parameters to *R*=0.0431 and *wR*=0.0518.

P07.07.070 A TRINUCLEAR RUTHENIUM(II) COMPLEX WITH RARE S,O-BRIDGING SULFOXIDE LIGANDS. P.H. van Rooyen, S. F. Lessing, S. Lotz and H.M. Roos. Department of Chemistry, University of Pretoria, Pretroia 0002, South Africa.

The trimetallic compound $[Ru_3(\mu\text{-}mpso\text{-}S,O)_2(\mu\text{-}Cl)_4(mpso\text{-}S)_4Cl_2]$ (*mpso* = C_7H_8OS, methyl phenyl sulfoxide) **1**, was prepared from hydrated $RuCl_3$ and methyl phenyl sulfoxide. A crystal structure determination of **1** revealed a linearly arranged molecule with three ruthenium atoms in distorted octahedral configurations with bridging chloro and S,O-*mpso* ligands. This is the first example of S,O-bridging sulfoxide ligands other than *dmso,* and where two such bridges are found between two Ru-atoms . For the Ru metals with triply bridged chloro ligands, the Ru - Cl - Ru angles are 81.8(4), 82.7(1) and 83.2(1)°, and the Ru...Ru non-bonded distance is 3.218A. In contrast, the Ru - Cl - Ru angle on the bridging *mpso* part of the molecule is 100.7 (1)°, and the Ru...Ru non-bonded distance is 3.686A. The configuration at sulfur on S2, S3, S4 and S5 is opposite to that at S1 and S6. In solution, the methyl resonances in the ^1H and ^{13}C NMR spectra of **1** are found in the δ-ranges of 3.81 - 2.70 and 49.7-44.9 ppm, respectively. The methyl resonances of the S,O-bridging *mpso* ligands are shifted upfield in the ^1H NMR spectrum, but furthest downfield in the ^{13}C NMR spectrum.



Ph = phenyl

P07.07.071 SPECTRAL SIMILARITY BETWEEN TETRACYANOPYRROLI-ZINATO METAL COMPLEXES AND PHTHALOCYANINES. V. Fares, A.Flamini, and A. Pifferi, ICMAT / ISC, Area della Ricerca del CNR, Roma, Italy.

The metal(II) complexes ML_2 of a tetracyanoethylene derivative, the ligand 1,2,6,7- tetracyano - 3,5 - dihydro -3,5-diimino-pyrrolizinide (L), show optical spectra, due to the π - π * transition, closely similar, specially in the low-energy region (Q band), to those of metal phthalocyanines MPc's, so that they could be used as spectroscopic models for better understanding the electronic structure of porphyrinic systems. In this context, by using polarized specular reflectance measurements on single crystals, the optical spectrum of FeL_2 was assigned in D_{2h} [1]. It was found that the Q band in this system is originated from four different electronic transitions ($Q_{(x)}$, $Q'_{(y)}$, $R_{(x)}$, $R'_{(y)}$). By analogy the same band in the MPc's (D_{4h}) should be composed of two electronic transitions ($Q_{(x,y)}$, $R_{(x,y)}$), in contrast with the widely accepted assignment, according to which the Q band in MPc's is due to a single electronic transition plus a vibronic component.

Recently we found that the acetylacetonide ligand (Acac) may coexist with L in coordinating the same metal center, and that the monopyrrolizinato ML(Acac) derivatives too have optical spectra stictly similar to the corresponding MPc's.

On these grounds, we synthesized and characterized a series of homologous monopyrrolizinates in order to compare their optical spectra with those of ML_2 and MPc's, with the aim of providing further experimental data for a rationalization of the observed spectra based on molecular orbital calculations.

Furthermore, the nickel complex NiL(DPM) (DPM = 2,4-t-butyl acac) shows an exceptional solvatochromism in solution by varying the coordination properties of the solvent.

The X-ray analysis of NiL(DPM) (1) and the corresponding pyridine solvate $NiL(DPM)(Pyr)_2.2Pyr$ (2) was undertaken. Given the micro-dimensions of its crystals, intensity data of compound 1 were collected on the synchrotron Hard X-ray Diffraction beam-line of ELETTRA (Trieste) and processed by DENZO and CCP4 programs. The structural results suggest that the observed solvatochromism is due to a large variation of the Q band in both energy and intensity related to a significant variation (0.19 □) of the Ni-N bond distances in the molecular plane.

P07.07.072 A NEW TRINUCLEAR COPPER(II) COMPLEX INVOLVING A PYRAMIDAL Cu_3 O(H) CORE. M. Liu-Gonzalez*and F. Sanz-Ruiz, Department of Termology, Faculty of Physics, University of Valencia, 46100 Burjassot, Valencia , Spain and S. Ferrer and Y. Bertomeu, Department of Inorganic Chemistry, Faculty of pharmacy, University of Valencia, 46100 Burjassot, Valencia , Spain.

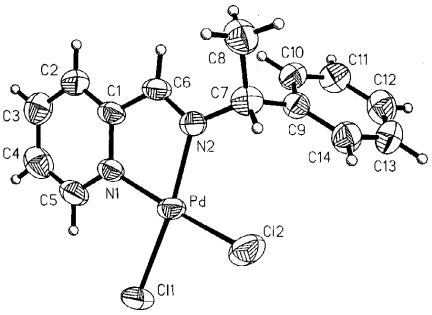
The reaction of the ligand Haaat (Haaat =3-Acetylamino-5-amino-1,2,4-triazol (3mmol) with copper nitrate (3 mmol) in presence of ethylendiamine (1 drop) in water has allowed us to isolate single crystals of $[Cu_3(aaat)_3(\mu_3\text{-}OH)(H_2O)_3)(NO_3)_2.(H_2O)$ (1), As far as we know, this is the first structure described of a compound of (H)aaat. The complex contains a triangular Cu_3 skeleton in which the copper atoms are held together by two bridging systems:(i) the oxygen atom of the tridentate OH group, and (ii) the *N1,N2*-diazinic groups from the triazole rings of three pseudo symmetry-related aaat ligands.

Crystal Data: $Cu_3O_{14}N_{27}C_{12}H_{27}$, Mr = 824.13, Triclinic, space group P-1, a =8.8518(12) Å, b = 11.491 (3) Å, c = 15.404 (3) Å, α = 70.43(3)º, β = 75.11(2)º, γ = 88.43 (3)º, V= 1423.8 (5) A^3 , Z = 2, D_X = 1.922 Mg/m^3, Mo Kα radiation (graphite crystal Monochromator, λ = 0.7173 Å), μ =2.315 mm^{-1}, F(000) = 834, T = 293 K., Final conventional R = 0.0828, and wR2 = 0.2326 for 3432 'observed' reflections and 460 variables. Throughout the experiments Mo Kα was used with a graphite crystal monochromator on a Enraf-Nonius CAD4 Single Crystal Diffractometer (λ= 0.71073 Å).

P07.07.073 SYNTHESIS AND CRYSTAL STRUCTURE OF N-2-PYRIDYL-METHYLIDENE-1-PHENYLETHYL-AMINE-PDCL$_2$ COMPLEXES. E. Lukevics, I. Iovel, A. Mishnev. Latvian Institute of Organic Synthesis, 21 Aizkraukles St., LV-1006 Riga, Latvia

The complexes of transition metals with optically active ligands, including Schiff bases, are used as the chiral inductors in a large number of the asymmetric catalytic processes. The complexes of $PdCl_2$ with imines have been derived from 2-pyridinealdehyde and (*R*)- and (*S*)-1-phenylethylamine (complexes **I** and **II** respectively). The palladium complex **I** ($C_{14}H_{14}N_2PdCl_2 \cdot 1/2$ 1,4-dioxane) crystallizes in $P2_1/c$ space group while complex **II** ($3\cdot C_{14}H_{14}N_2PdCl_2$) in $P2_1$.

The X-ray study of **I** and **II** confirmed the *cis* chelate co-ordination of the ligand and almost square-planar co-ordination geometry. In structure **I**



the Pd - Cl1, Pd - Cl2, Pd - N1 and Pd - N2 distances are 2.286(2), 2.270(2), 2.014(5) and 2.032(4)Å, respectively. The smallest bond angle at Pd atom is N1 - Pd – N2 = 80.7(2)°. Pyridine plane forms a dihedral angle of 6.1° with co-ordination plane. The phenyl ring is turned out from the co-ordination plane by dihedral angle of 74.8°. In crystal molecular fragments of the complex **I** form stacks with Pd...Pd intermolecular distances of 4.376 Å. Channels between the stacks are filled with 1,4-dioxane molecules. In structure **II** there are three independent molecules in the asymmetric unit cell. The molecules differ mainly by the orientation of the phenyl rings. The torsion angle N2-C7-C9-C10 assumes the values of 173, -125 and 143°, respectively. The values of bond lengths and angles averaged over the three molecules are nearly the same as their values in structure **I**.

P07.07.074 THE X-RAY CRYSTAL STRUCTURES OF THE $[Mo_2(V)O_2S(OCOCH(S)CH_3)_3]_2^-$ AND $[Mo_2(V)O_2S_2(OCOCH(S)CH_3)_2]_2^-$. M.Liu-Gonzalez*, F. Sanz-Ruiz [1], V. Sanz-Persiva, P. Palanca-Alandes [2], Esther García Rodriguez [3], S. García-Granda [3], [1] Departamento de Termología, Facultat de Física, Universitat de València, Spain. [2] Departamento de Química Orgánica, Facultat de Química, Universitat de València, Spain. [3] Departamento de Química Física, Universidad de Oviedo, Spain.

The reaction of $(NBu_4)_2[Mo_2(VI)O_2(OCOCH(S)CH_3)_2]$ with an excess of ac. 2-mercaptopropanoic in methanol yields the binuclear oxomolybdenum (V) complexes $(NBu_4)_2[Mo_2(V)O_2S(OCOCH(S)CH_3)_3]$ H_2O (1) and $(NBu_4)_2[Mo_2(V)O_2S_2(OCOCH(S)CH_3)_2]$ (2). The complex (1) exhibits the confacial bioctahedral geometry characteristic of this class of complexes in contrast with the tetrahedric geometry present in the complex (2). Crystal data. Complex 1: Triclinic space group P -1, a= 10.498(2) Å, b= 14.555(2) Å, c= 18.546(2) Å, α = 96.61(3)°, β = 101.64(3)°, γ = 97.86(3)°, V=2716.6(7)Å^3, Z= 2, D_x= 1.308 mg/m^3; structure solution and refinement based on 9571 'observed' reflections and 559 variables, R= 0.0666 and wR_2=0.1342. Complex (2): Triclinic space group P -1, a = 11.366(9) Å, b =11.429(8) Å, c = 20.450(12) Å, α = 96.42(4)°, β = 99.87(5)°, γ =101.56(10)°, V = 2535(3) Å^3, Z = 2, D_x = 1.286 mg/m^3; structure solution and refinement based on 9571 'observed' reflections and 559 variables, R=0.0666 and wR_2= 0.1342. Throughout the experiments Mo Kα was used with a graphite crystal monochromator on a Enraf-Nonius CAD4 single crystal diffractometer (λ = 0.71073 Å).

P07.07.075 ISOMER DISCRIMINATION OF $[Co(dien)_2]^{3+}$ ON FORMATION OF HALOGENOLEAD(II) SALTS. H. Miyamae, M. Iwaoka, M. Terakawa, G. Hihara, Department of Chemistry, Josai University, Keyakidai 1-1, Sakado-shi, Saitama 350-0295, Japan

Halogenolead(II) anion is a family of polymeric anion whose composition and structure show a dependence to the charge, size and shape of the counter cation in the salt.[1)] Here, we are going to depict new members formed with title cation.

When $[Co(dien)_2]X_3$ (dien=diethylenetriamine; X=Cl, Br or I) was mixed with PbX_2 in solution, two of three isomers of $[Co(dien)_2]^{3+}$ were discriminated forming *sym-fac*-$[Co(dien)_2](Pb_2Cl_7)$ (**1**), *mer*-$[Co(dien)_2]_2$- $[PbBr_6]Br_2$ (**2**), *sym-fac*-$[Co(dien)_2](Pb_3I_9)\cdot 2DMF$ (**3**), and *mer*-$[Co(dien)_2]$-$(Pb_4I_{11})\cdot 3DMF$ (**4**).

Except **2**, distorted octahedral 6-coordinated Pb atoms form 1D or 2D network in the crystal, while the cations are scattered in the cavity formed by the network. In **2**, it is very interesting that the highly negative charged $[PbBr_6]^{4-}$ ion is isolated between the *mer*-isomer of the cationic complex.

Crystal data: (**1**) Orange plate, Mr. 927.84, triclinic, P-1, a=8.833(4), b=9.764(3), c=7.611(3) Å, α=101.07(3), β=110.80(3), γ=96.73(3)°, V=589.8(4) Å^3, Z=1, Dx=2.611 g cm^{-3}, μ(Mo Kα)=15.38 mm^{-1}.

(**2**) Orange prism, Mr. 1376.97, monoclinic, $P2_1/n$, a=9.129(14), b=14.043(10), c=15.379(10) Å, β=101.29(8)°, V=1933(3) Å^3, Z=2, Dx=2.364 g cm^{-3}, μ(Mo Kα)=13.44 mm^{-1}.

P07.07.076 DINUCLEAR COPPER(II) COMPLEXES WITH SIMPLE PYRAZOLATE BRIDGES. E. Spodine, A. M. Atria, J. Valenzuela, Facultad de Ciencias Químicas y Farmacéuticas, Universidad de Chile. Casilla 233 Santiago, Chile, and J. Manzur, A. M. García, M. T. Garland, Facultad de Ciencias Físicas y Matemáticas, Universidad de Chile. Casilla 2777 Santiago, Chile.

Three new copper(II) dimeric complexes with simple pyrazolate bridges have been prepared: $[Cu_2(pz)_2(dpa)_2(Cl)(H_2O)]Cl\cdot H_2O$ 1, $[Cu_2(pz)_2(phen)_2Cl_2]\cdot 2C_2H_5OH$ 2 and $[Cu_2(pz)(phen)_2Cl_3]\cdot 2H_2O$ 3. (pzH: pyrazole, dpa: di(2-pyridyl)amine, phen:1,10-phenanthroline).

The crystal and molecular structures of complexes 1, 2 and 3 are reported. Complex 1 crystallizes in the orthorhombic system, space group $P2_12_12_1$; a = 13.892(2), b = 13.975(2) and c = 15.156(2) Å. Complexes 2 and 3 crystallize in the monoclinic system, space group C2/c; a = 25.753(2), b = 9.706(2), c = 16.627(5) Å, β = 125.86(2)° and a = 17.824(4), b = 11.612(2), c

= 13.647(3) Å, β = 106.01(2)º respectively. The copper centres in the binuclear cation in 1 have a square pyramidal geometry at Cu1 and a distorted octahedral geometry at Cu2. The neutral complexes 2 and 3 have the copper atoms in a distorted square pyramidal geometry. Complexes 1 and 2 are bibridged by pyrazolate bridges, while 3 is monobridged by this same ligand.

The crystal packing of complex 1 presents molecules in four different orientations. They are stabilized in infinite chains by hydrogen-bridged water and chlorine molecules. The packing of complex 2 is stabilized by ethanol molecules occupying the interstitial holes, which are hydrogen bridged to the terminal chlorine ions (Cl···O distance 3.256(5) Å). The crystal packing of compound 3 shows linear chains of complex molecules, joined by hydrogen bonded water molecules.

This research was supported in part by Fundación Andes and FONDECYT (projects 1980896-7980050). We are also grateful to the ECOS (France)-CONICYT (Chile) collaboration program (project C97E01).

P07.07.077 INTERPRETATION MODEL OF THE STRUCTURAL X-RAY RESULTS BASED ON HYPERCONJUGATIVE INTERACTIONS. I.A.Litvinov, A.T.Gubaidullin, O.N.Kataeva, A.E. Arbuzov Institute of Organic and Physical Chemistry, Russian Academy of Sciences, A.E.Arbuzov str., 8, Kazan 420088, RUSSIA.

The interpretation model of the molecular geometry derived from X-ray diffraction data, which gives good results in the structures of symmetric medium size 1,3,2-dioxa- and 1,3,2-diazaphosphacyclanes (from 5- to 8-membered), is extended on the new classes of non-symmetric sterically hindered structures of 1,3,2-oxaheterophosphorinanes, 5,6-benzo-1,2-oxaphospho-rines, 6,7-benzo-1,3,2- and 1,4,2-dioxa- and oxaza-phosphepines. It is shown, that steric ineractions may invert the anomeric effect of substituents. The observed changes of bond lengths are explained by electron density transfer as a result of hyperconjugative electronic interactions. This model is suitable not only to describe the bond length changes observed depending on the electron density transfer but also the difference of chemically equivalent bonds. The inversion of the anomeric interaction has been observed due to steric hindrance leading to the opposite distribution of the geometrical parameters The interpretation model is supported by the results of analysis of more than 30 structures.

On asymmetric 1,3,2-oxaheterophosphorinanes, asymmetrical 6- and 7-membered unsaturated cycles we can conclude the model of hyperconjugative stereoelectronic interactions satisfactorily describes the position of substituents at phosphorus. This model is also applicable to explain geometrical changes in the absence of strong intermolecular interactions — hydrogen bonds or anion-cation interactions.

This research was supported by Russian Foundation for Basic Research, grant 98-03-33266.

P07.07.078 STRUCTURE OF HEXAPHENYLGERM-OLE. John Ricci and Henry Tracy, Department of Chemistry, University of Southern Maine, Portland, ME 04104, USA and Wim Klooster, Chemistry Department, Brookhaven National Laboratory, Upton, NY 11973, USA.

We have undertaken the X-ray analysis of a phenyl-substituted Group14 metallacyclopentadiene, hexaphenylgermole (GePh), to determine the origin of the dramatic difference in luminescence between this compound and the methyl-substituted analog.

The structural features of the germanium methyl-substituted derivative have been described (1). The luminescence emission of the germanium phenyl compound (excitation at 350 ± 10 nm) exhibits a significant bathochromic shift from its methyl analog; emission is at 480 nm for GePh and 388 nm or GeMe.

We find the geometry of the heterocyclic ring carbon fragment in GePh to be identical to those in the previously published structures. Thus, it is proposed that the difference in luminescence properties must be electronic rather than structural in nature.

Crystallographic data: spacegroup P-1, Z = 2, a= 10.280(1), b=16.520(3), c = 9.641(2) α =100.20(2), β= 108.29(1), γ= 77.06(1) 5489 refls., $R(F^2)$ = 0.066, $R_w(F^2)$ = 0.111, S = 1.92.

P07.07.079 STRUCTURE OF SILYL AND GERMYL SUBSTITUTED THIOPHENE-1,1-DIOXIDES AND DIRECTION OF CYCLOADDITION. S.Belyakov, P.Arsenyan, O.Pudova, and E.Lukevics, Latvian Institute of Organic Synthesis, 21 Aizkraukles, Riga, LV-1006, Latvia.

The [2+3] dipolar cycloaddition of nitrile oxides to the double bond of thiophene-1,1-dioxides **1** has been investigated. It was shown that the reaction pathway strongly depends on the substituents M and M' in the heterocycle and the method of nitrile oxide generation. Cycloaddition proceeds with high regioselectivity. It should be noted that only one double C=C bond of **1** is involved into the interaction. The direction of cycloaddition was confirmed by X-ray structure analysis of fused isoxazoline **2** (M = C).

P07.07.080 SYNTHESIS AND STRUCTURE OF BIS(ARYLTELLURO)ETHYNES, ArTeC≡CTeAr. M.V. Capparelli[a,b], J. Farran[a], A. Alva-rez-Larena[a], J.F. Piniella[a] and L.Torres-Castellanos[c]. [a]Univ. Autónoma de Barcelona, Bellaterra, Spain; [b]Univ. Central de Venezuela, Caracas, Venezuela; [c]Univ. Nacional de Colombia, Bogotá, Colombia.

Although many telluroethynes (RTeC≡CR´) are known, only a few bis(alkyl-telluro)ethynes (AkTeC≡CTeAk) were described, and only one bis(aryltelluro)ethyne (ArTeC≡CTeAr) has been reported so far [1]. Within our program of synthetic and structural studies of organotellurium compounds [2] we prepared 12 new bis(aryltelluro)ethynes [Ar: C_6H_5(**1**), *p*-MeC_6H_4(**2**), *p*-MeO-C_6H_4(**3**), *p*-$Me_2NC_6H_4$(**4**), *p*-FC_6H_4(**5**), *p*-ClC_6H_4(**6**), *p*-BrC_6H_4 (**7**), *p*-IC_6H_4 (**8**), *p*-PhC_6H_4(**9**), *p*-$PhOC_6H_4$(**10**), α-$C_{10}H_7$(**11**), β-$C_{10}H_7$(**12**)] by reacting BrMgC≡CMgBr with the corresponding ArTeBr formed *in situ.* The X-ray crystal structures of **1**, **2**, **4**, **8** and **10** were determined.

All compounds display approximate linear Te-C≡C-Te moieties, in which deviations from the least-squares lines are small [0.0093(6)-0.067(7)Å]. Co-ordination at the Te atoms is angular, with C-Te-C angles [94.2(3)-97.2(2)°] substantially smaller than the tetrahedral value. As expected, the Te-C(sp^2) distances [2.103(5)-2.142(6)Å] are significantly longer than the Te-C(sp^1) bond lengths [2.021(6)-2.058(6)Å]. In all compounds the Te atoms are approximately coplanar with the bonded phenyl rings [max. dev.: 0.1503(4) Å]. The C(sp^2)-Te···Te-C(sp^2) torsion angles vary widely, due to the unhindered rotation about the Te-C(sp^1) bonds. This feature is the only important difference between the solid-state molecular geometries.

Although Te(IV) compounds show a tendency to form secondary bonds [2], this is not frequent in Te(II) compounds. Packing in **1**, **2**, **4**, **8** and **10** is mainly due to van der Waals interactions; non-bonded contacts shorter than the sum of van der Waals radii are only marginally so.

2. J. Farran, A. Alvarez-Larena, M.V. Capparelli, J.F. Piniella, G. Germain & L. Torres-Castellanos (1998), *Acta Cryst*., **C54**, 995, and refs. therein.

P07.07.081 MOLECULAR STRUCTURES OF THREE UNUSUAL TELLURIUM COMPLEXES. S. Husebye and K. W. Törnroos, Department of Chemistry, University of Bergen, 5007 Bergen, Norway, J. Novosad and M. Necas, Department of Inorganic Chemistry, Masaryk University, 611 37 Brno, Czech Republic and A. M. Z. Slawin and J. D. Woollins, Department of Chemistry, Loughborough University, Loughborough LE11 3TU, UK.

The three compounds, [Te_2(μ-Cl)$_2${$Ph_2P(S)NP(S)Ph_2$}$_2$], **1**, [(4-$MeOC_6H_4TeCl_3$)$_2$ {μ-$Ph_2P(S)(CH_2)_2P(S)Ph_2$}], **2**, and [Te_2(μ-Ph_2PS_2)$_2$], **3**, have been synthesized and their structures solved by means of conventional X-ray crystallographic methods. Complex **1** is a dinuclear, centrosymmetric, square planar Te(II) complex where each Te atom is coordinated to the two S atoms of the bidentate dithiolate ligand and the two bridging Cl^- ligands. In **2**, the dithio ligand is neutral and adds a 4-$MeOPhTeCl_3$ molecule at each S atom, thus bridging the two Te(IV) atoms. The coordination of both Te atoms is ψ-octahedral with the anisyl group and a lone pair of electrons in axial positions. Complex **3** is a binuclear Te(I) complex, mainly held together by a Te-Te bond. Both anisobidentate $Ph_2PS_2^-$ ligands bridge the two Te atoms. The resulting coordination around each Te atom is best described as T-shaped, with the Te-Te bond along the stem. The molecules are connected into zigzag chains by weak intermolecular Te---S contacts. The average Te-S bond length is 2.502 Å in **1,** compared to 2.797 Å in **2**. This difference is related to the difference in basicity of the ligands. Average Te-S bond lengths in **3** are 2.491 Å for the two strong bonds and 2.990Å for the two weaker ones. The Te-Te bond length in **3** is 2.730(1)Å while the Te-Cl bond lengths in **1** have an average value of 2.915Å and in **2** range from 2.425 to 2.534Å, those *trans* to S being shortest.

P07.07.082 CHEMICAL REACTION IN THE COORDINATION SPHERE OF Cu(II) ATOM AS A RESOURCE OF NEW ANIONIC CHELATE LIGANDS. M. Dunaj-Jurèo, D.Mikloš, Department of Inorganic Chemistry, Slovak Technical University, SK-812 37 Bratislava, Slovak Republic, and I.Potoèòák, Department of Inorganic Chemistry, P. J. Šafárik University, SK- 041 54 Košice, Slovak Republic

The non-linear pseudohalide anions $ONC(CN)_2^-$, $N(CN)_2^-$ and $C(CN)_3^-$ are known to have good coordination ability. For the first two of them nucleophilic addition reactions have been observed which lead to formation of new chelate anionic ligands in the coordination sphere of the Cu(II) atom. Crystal structures of [Cu(bipy)(mcoe)(NCO)] [1], [Cu(bipy)(mcoe) ($ONC(CN)_2$] [2], [Cu(bipy)(mcoe)($N(CN)_2$] [3] and [Cu(bipy)(coe)] [1] are presented, and supplemented by [Cu(mcoe)$_2$ (H_2O)$_2$] [4] [Cu(ecoe)$_2$ (H_2O)$_2$] [5], and [Cu(mici)$_2$] [6], where *bipy* = 2,2'-bipyridine, *mcoe*, *ecoe*, *coe* and *mici* are the anionic chelate ligands *m*ethyl(2-*c*yano-2-imido*x*y *e*thaneimidate), [(ON)(NC)C-C(NH)(OCH_3)]$^{1-}$, *e*thyl(2-*c*yano-2-imido*x*y *e*thaneimidate), [(ON)(NC)C-C(NH)(O-CH_2 -CH_3)]$^{1-}$, 2-*c*yano-2-imido*x*y *e*thaneimidate, [(ON)(NC)C-C(NH)(O)]$^{2-}$ and di*m*ethyl*i*midodi*c*arbon- *i*midate, [(HN)(CH_3O)C-N-C(OCH_3)(NH)]$^{1-}$, formed by nucleophilic addition of methanol, ethanol and hydroxide ion to the coordinatively activated β-carbon of the nitrosodicyanomethanide (*mcoe*,*ecoe*,*coe*) or methanol to the dicyanamide (*mici*) anions. Formation of the hydroxide ion from water in the reaction mixture can be explained by protonation of the $C(CN)_3^-$ anion.

P07.07.083 ACTIVE LONE-PAIR INFLUENCE ON THE COORDINATION BETWEEN LEAD(II) AND OXYDIACETIC ACID. S. Norberg, G. Svensson, S. Olson and J. Albertsson, Department of Inorganic Chemistry, Chalmers University of Technology, SE-412 96 Göteborg, Sweden. E-mail: stn@inoc.chalmers.se

Lone-pair electron activity in two different lead(II) oxydiacetic acid complexes is described. The complexes are, $Pb(C_4H_4O_5)(H_2O)$ [1] and $Pb_4(C_4H_4O_5)_3(NO_3)_2(H_2O)$ [2].

The oxydiacetate ligand $[O_2C—CH_2—O—CH_2—CO_2]^{2-}$ can be mono-, bi- or tridentate and may form bridges between metal atoms. By using a multi-dentate ligand the $6s^2$ lone-pair electrons in Pb(II) are likely to actively affect the coordination polyhedron around the Pb atom.

In $Pb(C_4H_4O_5)(H_2O)$ a distorted square antiprism is formed and the lone-pair $6s^2$ electrons show stereochemical activity. The Pb—O distances are in the range 2.49(3)-2.909(17)Å. The shortest distances are found on the opposite side of the lone-pair, which is in accordance with the VSEPR theory. $Pb_4(C_4H_4O_5)_3(NO_3)_2(H_2O)$ comprises of three crystallographically independent Pb atoms , with coordination numbers seven, eight and nine. At least the seven- and eight-coordinate Pb atoms are influenced by a stereochemically active lone-pair.

P07.07.084 STRUCTURAL STUDIES OF THE NOVEL Hg(II) COMPLEXES WITH 3,4,5,6-TETRAHYDRO-2-PYRIMIDINETHIOL. D. Matković-Čalogović, Z. Popović, G. Pavlović and Ž. Soldin, Chemistry Department, Faculty of Science, University of Zagreb, Ul. kralja Zvonimira 8, 10000 Zagreb, Croatia

Toxicity of mercury(II) and methylmercury(II) cations in biological systems derives from the affinity of these ions for cysteinyl sulphur residues. Heterocyclic thiols can be used to mimic bio-relevant mercury(II)-sulphur interactions. A series of complexes HgX_2L_2 and HgX_2L (X = Cl^-, Br^-, I^-, CN^-, SCN^-; L = H_4pymtH, 3,4,5,6-tetrahydro-2-pyrimidinethiol) has been prepared and characterized by elemental chemical analysis, NMR and IR spectroscopy and thermal analysis (TGA and DSC). X-ray powder data showed that the complexes are not isostructural. Crystal structures of $HgCl_2(H_4pymtH)$ (1), $Hg(SCN)_2(H_4pymtH)_2$ (2) and $HgBr_2(H_4pymtH)_2$ (3) have been determined by single crystal X-ray diffraction. *Crystal data*: (1) $C_{16}H_{32}Hg_4Cl_8N_8S_4$, *Mr*=1550.74, triclinic, *P* $\bar{1}$, *a*=10.045(2), *b*=13.530(2), *c*=14.162(2) Å, α=103.01(1), β= 92.00(2), γ=90.34(2)°, *Z*=2, $D_{calc.}$=2.748 gcm^{-3}, μ=17.2 mm^{-1}, *R*=0.062, R_w=0.085 for 4900 reflections with $I \geq 2\sigma(I)$. (2) $C_{10}H_{16}HgN_6S_4$, *Mr*=549.10, triclinic, *P* $\bar{1}$, *a*=7.6508(7), *b*=8.4976(7), *c*=14.1751(22)Å, α=105.97(1), β= 89.94(1), γ=92.00(1)°, *Z*=2, $D_{calc.}$=2.060 gcm^{-3}, μ=9.14 mm^{-1}, *R*=0.057, R_w=0.070 for 2964 reflections with $I \geq 2\sigma(I)$. (3) $C_8H_{14}HgBr_2N_4S_4$, *Mr*=592.76, monoclinic, $P2_1/c$, *a*=7.870(1), *b*=15.644(2), *c*=12.882(2)Å, β=98.79(2)°, *Z*=4, $D_{calc.}$=2.512 gcm^{-3}, μ=15.1mm^{-1}, *R*=0.040, R_w=0.049 for 1828 reflections with $I \geq 2\sigma I$.

Complex 1 is tetrameric with two tetrahedral $HgCl_4$ moieties and two Hg atoms with short Hg-S (from H_4pymtH) bonds and longer Hg···Cl interactions in a 2+2 coordination sphere. In the structures of 2 and 3 there are discrete molecules with tetrahedrally coordinated mercury. In 2 the coordination sphere is built up of four S atoms, two from the tiocyanate and two from the zwitterionic thionate ligand. In 3 two Br atoms and two S atoms from the thionate ligand complete the coordination sphere.

P07.07.085 CRYSTAL CHEMISTRY OF HETEROCOMPLEX COMPOUNDS OF LEAD AND COPPER BIS- β-DIKETONATES. V.V. Krisyuk, P.A. Stabnikov, I.A. Baidina, I.K. Igumenov, Institute of Inorganic Chemistry SB RAS, Novosibirsk, Russia, 630090, Lavrentiev Avenue 3.

The coordination unsaturation of lead atom in beta-diketonate complexes has allowed to assume an opportunity of saturation of coordination sphere of central atom by additional ligands at formation of crystals from investigated lead complexes and beta-diketonates of other metals. For experiment lead bis-hexafluroacetylacetonate - Pb(hfa)2 and complexes of copper(II) were chosen. At crystallization from organic solvent the heterocomplex compounds were obtained with composition $Pb(hfa)_2$*$Cu(hfa)_2$, $Pb(hfa)_2$*$Cu(aa)_2$, $Pb(hfa)_2$*$Cu(zis)_2$, where aa = acetylacetonate, zis = 2-methoxy-2,6,6-trimethylheptane-3,5-dionate.

X-ray diffraction and crystal analysis have confirmed the single phase and shown that irrespective of composition of initial solution only 1:1 heterocomplexes have been separated. Carried out crystal structure investigation of new compounds has allowed to establish features of packing of molecules and coordination behavior of metal atoms.

P07.07.086 CRYSTAL STRUCTURES OF THE NEW ALKALI METAL BORATOBORATES $Rb_8B_{12}(BSe_3)_6$, $Rb_4Hg_2B_{12}(BSe_3)_6$ AND $Cs_4Hg_2B_{12}(BSe_3)_6$. Arno Lindemann, Joachim Kuchinke, Christian Köster and Bernt Krebs, Anorganisch-Chemisches Institut der Universität Münster, D-48149 Münster, Germany

The three new alkali and alkali-mercury selenoboratoborates were synthesized by reaction of stoichiometric amounts of the metal selenides, amorphous boron and selenium in carbon coated, evacuated silica tubes at higher temperature. The novel chalcogenoborates contain B_{12} icosahedra completely saturated with selenium ligands. Six trigonal-planar selenoborate entities functioning as bidentate ligands complete the B_{12} icosahedron to form a persubstituted closo-dodecaborate ion. Besides $Cs_8B_{12}(BSe_3)_6$ [1,2] which we have described recently, these compounds are further examples of the new class of boron clusters yielded from solid state reactions. $Rb_8B_{12}(BSe_3)_6$ crystallizes in the triclinic space group P-1 with a = 10.542(5) Å, b = 10.450(3) Å, c = 10.946(4) Å, α = 104.53(3)°, β = 91.16(4)°, γ = 109.11(3)° and Z = 1. The complex $[B_{12}(BSe_3)_6]^{8-}$-anions are interconnected via eight rubidium cations. These are eight- and ninefold coordinated by selenium atoms, respectively.

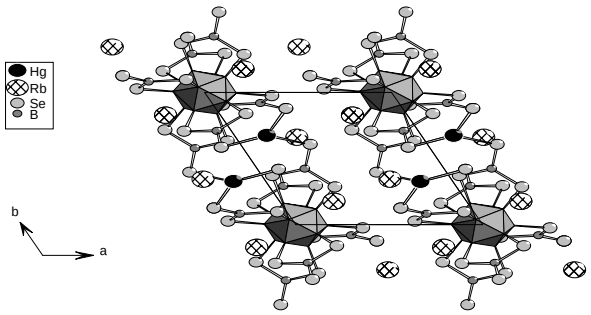

Fig. 1: Projection of $Rb_4Hg_2B_{12}(BSe_3)_6$ along the c-axis

The compounds $Rb_4Hg_2B_{12}(BSe_3)_6$ (A) and $Cs_4Hg_2B_{12}(BSe_3)_6$ (B) contain the same type of anions. Substitution of four monovalent cations by two bivalent Hg-cations results in a new layered structure of space group P-1. The crystal data for the selenoborates are given below.

A: a = 9.560(2) Å, b = 10.418(2) Å,c = 11.104(2) Å,
α = 99.27(3)°, β = 91.08(3)°, γ = 116.33(3)° (at T = 213 K);
B: a = 9.838(2) Å, b = 10.716(2) Å, c = 11.081(2) Å,
α = 99.82(3)°, β = 90.80(3)°, γ = 116.08(3)° (at T = 293 K).

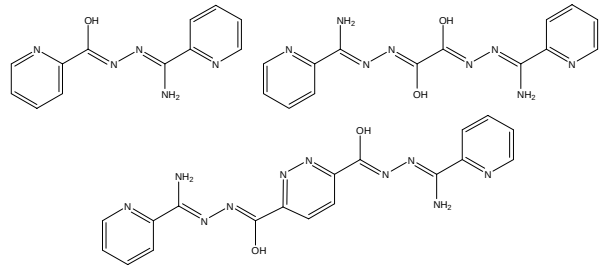
P07.07.087 STRUCTURAL STUDIES OF SYNTHETIC PB AND CA APATITES. J.Y. Kim, B.J. Kennedy and R.R. Fenton, School of Chemistry, University of Sydney, N.S.W., 2006, Australia, and B.A. Hunter, ANSTO, PMB 1 Menai, N.S.W., 2234, Australia.

Hydroxyapatite, $Ca_{10}(PO_4)_6(OH)_2$, is a major mineral component of calcified tissues, including bones and teeth. It is a



good model system for natural apatites, having a structure which can easily accommodate a great variety of anionic and cationic substitutions. It acts as a natural sink for heavy metals, especially Pb and Cd, in biological systems. The hydroxyl ion can be partially replaced by other anions and one aim of the present work is to establish how such substitutions influence the ability of apatites to sequest and immobilise heavy metals. We have used a combination of synchrotron X-ray diffraction and high resolution powder neutron methods for our structural studies, of some substituted apatites.

We have refined the structures of eight apatites $M_{10}(PO_4)_6X_2$, M = Pb, Ca and X = OH, F, Cl, Br, using the Rietveld method. In these there are two cation sites, a channel of M-I atoms and a triangle of M-II atoms. The anion interacts most strongly with the M-II atoms at (., ,. ,¼). For the Ca compounds, the F ion sits within the triangles at (0, 0, 0), while the larger OH and Cl anions are disordered above and below the M-II triangles. The Br is at (0, 0, ½). Despite the larger size of the isostructural Pb compounds, no anions are found in the triangles. The F, Cl and Br ions are at (0, 0, ½) and the OH ion is disordered at (0, 0, *z*). This difference in behaviour is possibly related to the stereochemical activity of the Pb 6s electrons.

While synchrotron X-ray methods have been important in determining the positional parameters of the heavy elements (Pb, Ca *etc*.), neutron scattering methods have been essential in determining the positional parameters of the lighter elements (H, F, O *etc*.) in the presence of the heavy Pb atom. In this paper we present both the experimental results and discuss the possible reasons for the observed differences.

P07.07.088 THERMAL BEHAVIOUR OF STRUVITE-CONTAINING URINARY STONE. T.A. Korneva, T.N.Grigor'eva, and N.A. Palchik. United Institute of Geology, Geophysics and Mineralogy, Siberian Branch of Russian Academy of Science, Novosibirsk 630090, Russia.

A human urinary stone weighing as much as 105g was composed of different colour concentric layers. Three specimens separated from the urinary stone were distinguished by their colour (white, brown, and yellow). X-ray showed that all three specimens consisted mainly of struvite $MgNH_4PO_4{\cdot}6H_2O$ with cell parameter *a* ranging from 6.901 to 6.988 Å for different samples and with lattice constants *b*=11.19 Å and *c*=6.15Å. The spectrum analysis of struvite has revealed the significant content of Ca and Na and trace of Cu, Mn, and Sr. DTA along with TGA indicated the removal of the major amount of water of crystallization and NH_3 up to temperature of about 220°C. X-ray of the specimen heated at that temperature showed the presence of nearly X-ray amorphous struvite with only two broadened (200) and (040) reflections. After exothermic effect on the DTA curve at 360° connected with removal of organic matter (about 1.0%) no changes was observed by thermal and X-ray analyses up to 660°C. The practically amorphous anhydrite product was recrystallized exothermically at ≈660°C When the specimen was heated at 670°C, X-ray pattern showed the phase corresponding to sufficiently crystallized Mg -pyrophosphate and whitlockite. The trace of the crystalline phase with apatite structure was observed likewise. After the second exothermic reaction, the further crystallization proceeded during glass transition. The specimen heated at 1000°C constituted a hardened glass-like substance. X-ray pattern of the substance exhibited well crystallized Mg-pyrophosphate $Mg_2P_2O_7$, whitlockite, $Mg_3(PO_4)_2$, and trace of oxyapatite. The total weight loss of the specimen in the temperature interval from 20 to 1000°C was 41.8% whereas the theoretical content of volatile in struvite is 51,42%. It follows that the urinary stone investigated was not completely consisted of struvite, but contained X-ray amorphous Ca-rich phase. The work is supported by RFFI grant N 97-05-65305.

P07.07.089 UNUSUAL CRYSTAL MORPHOLOGY OF TWO BIOMINERALS: BARIUM SULFATE AND STRONTIUM SULFATE B. Hasse, M. Epple, Institute of Inorganic and Applied Chemistry, University of Hamburg, Martin-Luther-King-Platz 6, D-20146 Hamburg, Germany

Barium sulfate (baryte) and strontium sulfate (coelestine) are found in the living nature as biominerals: BaSO4 is used as gravity sensor and SrSO4 serves as skeleton for a class of deep-sea single-cell organisms (acantharia). Nature has developed ways to grow such highly insoluble materials in desired shape and morphology. Conventional crystallization in a chemist's laboratory by adding solutions of cations and anions usually results in rapid crystallization of unstructured, micrometer-sized crystals due to fast nucleation. In order to mimic natural processes, it is imperative to slow down the nucleation and crystal growth process.

We have crystallized both earth alkaline sulfates in and on a porous polymer matrix containing micrometer-sized pores. Barium sulfate aggregates were found either as platelets or as highly ordered aggregates of small spheres. Strontium sulfate crystallized in rhombohedrical crystals that showed other different crystallographic faces compared to natural coelestine. In early stages of strontium sulfate crystallization, porous crystals were found.

Mixed crystals of BaSO4 and SrSO4 of different composition were also precipitated. The morphology changed from spherical to rhombohedrical crystals with increasing strontium content. These results may help to understand biological crystallization of earth alkaline sulfates.

P07.07.090 BIOMIMETIC GROWTH OF CALCIUM PHOSPHATES IN AND ON POROUS POLYMERS M. Epple, F. Peters, K. Schwarz, Institute of Inorganic and Applied Chemistry, University of Hamburg, Martin-Luther-King-Platz 6, D-20146 Hamburg, Germany

Among the most important inorganic materials used by nature as building block in the living world are calcium phosphates, namely, apatite phases. The parent compound is hydroxyapatite $Ca_{10}(PO_4)_6(OH)_2$ that occurs in mammalian bone as nanometer-sized crystals that are crystallized in a matrix of collagen. The ability of hydroxyapatite to incorporate other cations (e.g., Mg^{2+}) and anions (e.g., CO_3^{2-}, F^-, Cl^-) makes it a very flexible material whose biological and mechanical properties can be adjusted in a wide range.

Control of the crystallization process is necessary to prepare larger crystals of apatite. We have slowed down the nucleation process by employing a double-diffusion technique where two solutions containing Ca^{2+} and PO_4^{3-} were separated by a porous polymer matrix with pores in the sub-micrometer range. Under these conditions, the crystallization time was of the order of weeks. Unusual growth morphologies were observed inside the polymer matrix: elongated hexagonal prisms with fractal growth for fluoroapatite $Ca_{10}(PO_4)_6F_2$ and oriented flat hexagonal platelets for hydroxyapatite. Other experiments involved the controlled crystallization of hydroxyapatite on porous polymers where nucleation took place on the polymer surface. The results are compared to structural investigations on natural bone samples with various methods (diffraction, EXAFS, thermal analysis).

P07.07.091 LOW TEMPERATURE STRUCTURAL STUDIES OF MAGNETICALLY INTERESTING CLUSTER COMPLEXES. R. S. Hampshire[$], C. Wilson[$], L. K. Thompson[#], J. A. K. Howard[$]. $ - Dept. of Chemistry, University of Durham, Durham DH1 3LE, UK. # - Dept. of Chemistry, Memorial University of Newfoundland, St. John's, Newfoundland A1B 3X7, Canada.

Currently[1,2] there is much interest in polynuclear transition metal cluster complexes that exhibit interesting magnetic properties. One series of compounds that we are studying includes polynuclear transition metal complexes of a group of substituted diazine ligands (Fig. 1).

Fig. 1 Diagrams of the ligands PHAAP, PTTP and PPDP respectively.

Clusters derived from these ligands show a wide variety of structural arrangements, e.g. Chains, Squares, Spirals, Trigonal Bi-Pyramids and Tetrahedra, although we believe that not all possible conformations have as yet been determined for this particular series of compounds.

Structural results on several structural types will be presented at the meeting.

P07.07.092 TWO SPIN ISOMERS IN THE SAME CRYSTAL. Alan Hazell, Chemistry Dept. Aarhus University, DK-8000 Århus. C, Denmark, and Benoit Chansou and Hans Toftlund. Chemistry Dept. Odense University, DK-5230 Odense.M, Denmark.

Fe(II) forms octahedral complexes with a d ^{6} electron confguration and can exist either as low spin (t_{2g}^6) or high spin ($t_{2g}^4 e_g^2$) species. We have studied several polypyridyl Fe(ii) complexes: [Fe(tpa)$(NCS)_2$)] incorporating various solvate molecules and [Fe(btpa)]$(PF_6)_2$, and find that three of these crystallize with two complexes in the asymmetric unit with one complex low-spin while the other is high-spin. On cooling the tpa complexes there is a spin cross-over so that both Fe atoms are essentially low spin, this process is reversible.

The average Fe-N distances, in Å, are:

	2 95K	1 20K	1 00K
[Fe(tpa)$(NCS)_2$.CH_3CN	2 .057 2.152	1 .960 1.964	1 .958 1.963
[Fe(tpa)$(NCS)_2$.C$_2$H$_5$OH	2 .092 2.145	1 .959 1.964	
[Fe(tpa)$(NCS)_2$.C$_5$H$_5$N	2 .168	crystal splits on cooling	
[Fe(btpa)]$(PF_6)_2$	1 .989 2.230	1 .993 2.243	

The structures of two Fe doped [Zn(tpa)$(NCS)_2$)] complexes will also be presented.

(tpa = tris(2-pyridylmethyl)amine; **btpa** = 6,6'-bis[bis(2-pyridylmethyl)aminomethyl]-2,2'-bipyridine)

P07.07.093 ANALYSIS OF THE CHEMICAL BONDING IN HOMOGENEOUS SETS OF STRUCTURES CREATED WITH CAMBRIDGE DATABASE. Carlo Mealli, ISSECC-CNR, Via J. Nardi 39, 50132 Firenze, Italy.

Mononuclear and polynuclear transition metal compounds, expected to be similar on the basis of simple chemical rules are, can show remarkably different structures. This occurs for compounds having the same metal-ligand framework and a consistent number of valence electrons: a change of the metal (within the same triad) or of the ligand donor strength (also related to the substituents steric hindrance) can have dramatic effects. On the other hand, the addition or removal of electrons within a given framework (electron tuning) causes alternative structural rearrangements.

The author has explored whole categories of compounds by searching exhaustively within the Cambridge Database. The screened structures are tabulated in terms of significant stereochemical parameters, total electron count, nature of metals, number and type of the ligands, etc. Among others the following species have been analyzed in detail: *i)* octahedral M_6 Clusters [1] *ii)* dimers containing coniugate chelates with N_2, P_2 or S_2, donors riding L3M-ML3 sawhorses [2] *iii)* dimers with the inner core M_2X_2 (X= naked chalcogenide atom) which is present in many molecules with biological and catalytic relevance [3]. *iv)* species with the $M_3(\mu\text{-}PR_2)_2$ framework [4] *v)* Pd_2 or Pt_2 dimers with a single phosphido bridge [4].

The interpretional tool of the chemical bonding is the MO theory, both *ab-initio* and qualitative. The latter approach, facilitated by the graphic interface offered by the package CACAO [6], still allows to draw important correlations between the structural prototypes and is rich of chemical hints.

P07.07.094 NONCOVALENT BONDING INTERACTIONS ASSISTED WITH OFURAN IN MG AND CA FURANCARBOXYLATES. B. Paluchowska, Jan K. Maurin, Institute of Atomic Energy, 05-400 Swierk-Otwock, Poland.

Molecular modeling studies of 2- and 3-furancarboxylic acids (2-FA and 3-FA) and their complexes with magnesium and calcium had been carried out to elucidate electrondonor properties of the furan ring oxygen atom. Ab initio studies of 3-FA packing forces indicates the importance of O-H···Ofuran and O-H···Ofuran bonding interactions. Subsequently, semiempirical calculations on Mg 2-FA, Mg 3-FA, Ca 2-FA and Ca 3-FA models, which had been constructed taking into account gained knowledge about ligand binding preferences, shows some general features of ligand-metal interactions.

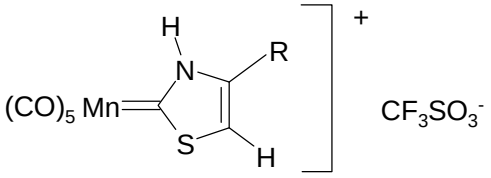
X-ray single crystal data for Ca 2-FA confirmed, that the furan ring oxygen is involved in chelating calcium cations, leading to the formation of five-membered rings (Ca-Ofuran-Cring-Ccarboxyl-Ocarboxyl). In the case of Ca 3-FA real crystal the packing arrangement of the molecules is maintained by C-H···Ofuran hydrogen bonds. In studying Mg 3- and 3-furancarboxylate complexes the Ofuran activity is observed in second coordination sphere, most probably due to the rigidity of Mg surrounding octahedron.

P07.07.095 TWO NOVEL MANGANESE CARBENE COMPLEXES. D.G. Billing, Department of Chemistry and Biochemistry, Rand Afrikaans University, Johannesburg, 2006 South Africa and A;. Neveling; H.G. Raubenheimer; S. Cronje. Department of Chemistry, University of Stellenbosch, Stellenbosch 7600, South Africa.

We recently synthesized cationic carbene complexes (compounds **I** and **II**) by alkylation and protonation of the pentacarbonyl complexes, using the common reagents CF_3SO_3Me and CF_3SO_3H. Crystals suitable for crystallographic study were grown from dichlorormethane. The complexes were also characterized by MS, IR-, ^{1}H-NMR- and ^{13}C-NMR spectroscopy. A search through the Cambridge database revealed that although many manganese pentacarbonyls of the type $RMn(CO)_5$ (R = alkyl and aryl) have been synthesised and characterized, no manganese carbenes are known.

I : R = H

II : R = Me



The crystal structures of **I** and **II** represent the first complete characterization of this bonding type, with an average Mn-C(carbene) bond length of 2.03 Å.

P07.07.096 STRUCTURE *VS.* REACTIVITY: RHODIUM(I) CENTRE ACCESSIBILITY BY INTERCHANGING TERTIARY PHOSPHINES WITH ARSINES AND STIBINES. A. Roodt, S. Otto, and S.N. Mzamane, Department of Chemistry, University of the Free State, P.O. Box 339, Bloemfontein, 9300, South Africa.

Solid state and solution investigations were done on the effect of tertiary **arsine** and **stibine** and variations of phospine ligands in Rh(I) models to Vaska's complex, *trans*-$[Ir(CO)(Cl)(PPh_3)_2]$ (widely recognized for different catalytic reactions).

Upon introduction of $SbPh_3$, the novel five-coordinate trigonal bypyrimidal tris-tertiary stibine complex of Rh(I), *trans*-$[Rh(CO)(Cl)(SbPh_3)_3]$, is formed, which will be presented. The structures of the isomorphous $[Rh(CO)(Cl)\{Y(p\text{Tol})_3\}]$ (Y = P, As) were also done [1] and the reactivity with regard to iodomethane oxidative addition rate showed direct correlation with the 'cavity' available at the Rh(I) centre in an associative process.

Next, an example of how a range of these complexes were used to quantify the electronic effect of a tertiary phosphine, PPh_2Fc (ferrocenyldiphenylphosphine) is illustrated. This include correlations between IR, ^{31}P NMR and structural effects vs. kinetic data.

NMR and crystallographic investigations were also done to extend the series and include a range of tertiary arsine and stibine complexes – a field very limitedly exploited to date.

P07.07.097 MOLECULAR STRUCTURE OF HYDROGEN-CARBONATO-BRIDGED DINUCLEAR COPPER(II) COMPLEX: $[Cu_2(L)(HCO_3)](ClO_4)_2$. N. Kanehisa and Y. Kai, Department of Materials Chemistry, Graduated School of Engineering, Osaka University, Suita Osaka 565-0871, JAPAN and Y. Nishida, A. Yatani and Y. Nakao, Chemical Laboratory, Faculty of Education, Okayama University, Okayama 700-8530, JAPAN.

The increase of CO_2 concentration in atmosphere is coming a serious problem because of the rise of atmospheric temperature. A study on CO_2 fixation is now one of the most attractive current topics.

Recently, Nakao et al. reported the first X-ray structure analysis of hydrogencarbonato-bridged dinuclear copper(II) complex $[Cu_2(L)(HCO_3)]$- $(BF_4)_2.5H_2O$ (**1**) [1] obtained by leaving the solution containing a copper(II) complex $[Cu_2(L)(OH)](BF_4)_2.6H_2O$, where HL is *N,N,N',N'*-tetrakis[(1-methyl-2-benzimidazoyl)methyl]-2-hydroxy-1,3-diamino-propane. Bridged HCO_3^- moiety is considered to come from the atmospheric CO_2. Recently, we prepared and isolated a new copper(II) complex **2** having ClO_4 instead of BF_4 of complex **1** from $Cu(ClO_4)_2.6H_2O$, HL and $NaHCO_3$. We took the X-ray structure analysis of complex **2** to consider CO_2 fixation mechanism by the dinuclear copper(II) complex.

It is found that the complex **2** is isomorphous with **1**. Therefore, it may be considered that the complex **2** is also hydrogencarbonato-bridged dinuclear copper(II) complex although the hydrogen atom of bridged HCO_3^-moiety could not be located. It may also be considered that there is a possibility of obtaining complex **2** by adopting CO_2 in atmosphere through the synthetic process.

P07.07.098 ELECTRON DELOCALIZATION IN -N=C-C=N- BRIDGED COBALT CHELATE. M. Klinga, T.V. Laine and M. Leskelä, Laboratory of Inorganic Chemistry, University of Helsinki, Box 55, 00014 Helsinki, Finland.

In our study of late transition metal based catalyst precursors for ethene polymerization we have determined the crystal structure of a cobalt(II) complex with a symmetric bidentate ligand in which diimine bridge connects two bulky aromatic groups. Complexation leads to aromatization of the bridge itself with bond lengths N=C, C-C and C=N are 1.340(12), 1.33(2) and 1.340(12) Å, respectively. The angles N=C-C and C-C=N are both for symmetry reasons 119.6(5)°. In the pure ligand the bond distances in -N=C-C=N- bridge are typical for this kind of conjugated double bond system, namely 1.266(3), 1.467(5) and 1.266(3) Å.

There are only few examples in the CSD where the bond lengths and angles resemble our situation even if the estimated standard deviations are taken in account. Also found in the CSD are examples in which a transition metal chelate and the corresponding ligand have crystallized in the same structure and there is no indication of delocalization in the bridge due to chelatization.

P08.07.001 ADAMANTANE-LIKE CAGE TERTIARY PHOSPHINE LIGANDS: MOLECULAR MECHANICS AND CRYSTALLOGRAPHY STUDIES. Hirihattaya Phetmung and A. Guy Orpen, School of Chemistry, University of Bristol, Cantock's Close, Bristol, BS8 1TS, UK.

Adamantane-like tertiary phosphine complexes *trans*-$PdCl_2L_2$, **I**, and *trans*-$RhCl(CO)L_2$, **II**, (L = $PhP(CH_2)_2O_3(CCF_3)_2(CMe)_2$) have been studied by molecular mechanics (MM2 and UFF force fields)[1,2] and X-ray crystallographic methods. Both are four-coordinate d^8 metal complexes with square planar geometries. The structures show large variation of ligand-metal-ligand and intra-ligand bond angles from ideal values. The sterically demanding nature of the cage ligand is shown by its cone angle of 166.5° of **I** (*cf.* 145° for PPh_3)[3]. The X-ray determined geometries are in good agreement with those from molecular mechanics.

P08.07.002 ANION AND GUEST MOLECULE SITES WITHIN THE TUNNELS AND CAVITIES OF "CHINESE LANTERN" CRYSTALS. Wendy I Cross, Department of Chemistry, University of Manchester Institute of Science and Technology, PO Box 88, Manchester, M60 1QD, UK.

The molecular structure of the transition metal complex $[Mn_2(\mu\text{-}dppO_2)_4(NCS)_2](NCS)_2$, 1 [$dppO_2$ = $Ph_2P(O)(CH_2)_3P(O)Ph_2$] was structurally characterized by X-ray crystallography(1) and was dubbed the "Chinese Lantern" owing to its unusual shape (Fig1).

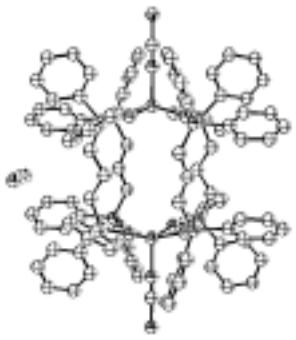

Fig1. The Chinese Lantern structure, 1

Furthermore, it was found to reversibly adsorb sulfur dioxide thus making it a potentially useful compound for the removal of sulfur dioxide from flue gas emissions.

The complexes $[Mn_2(\mu\text{-}dppO_2)_4(X)_2]X_2$, X = Cl, Br, I have been synthesized and structurally characterized by single crystal X-ray diffraction. The complexes all crystallize in the same space group (Tetragonal, I4/m) and superficially appear similar to complex 1. However, by varying the size of the anion, fundamental changes in the molecular structure are observed. The crystal packing of all the complexes reveals the presence of tunnels and cavities running through the structure in which anions and guest molecules such as sulfur dioxide may be found.

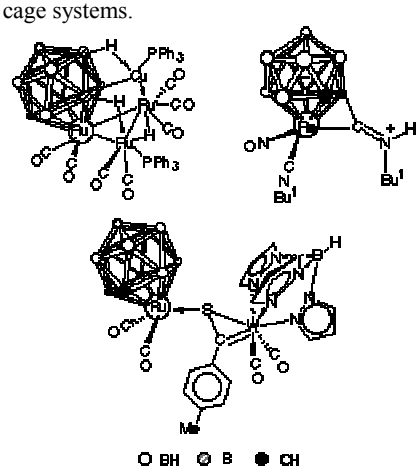
P08.07.003 CRYSTAL STRUCTURES OF NOVEL CARBORANE COMPLEXES. Dianne Ellis*, A. Franken, P. A. Jelliss, J. M. Malget and F. G. A. Stone, Department of Chemistry, Baylor University, Waco, TX 76798 U.S.A.

Co-workers in this laboratory have prepared a series of complexes using $[\eta^5\text{-}nido\text{-}7\text{-}CB_{10}H_{11}]^{3-}$ and $[\eta^5\text{-}nido\text{-}7,8\text{-}C_2B_9H_{11}]^{2-}$ ligands exhibiting a variety of co-ordination modes for the cage systems.



The formation of *closo*-metallacarboranes from reactions of these 11-vertex *nido*-carboranes with low valent metals, has shown that the cages can adopt a non-spectator role utilising bonding to exopolyhedral groups as well as the traditional pentahapto ligation modes. This poster will illustrate a number of these molecules whose structures have been established using X-ray diffraction.

P13.07.001 HYDROTHERMAL SYNTHESIS AND CRYST STRUCT OF 1 OR 2D POLYOXOANION CLUSTERS BRIDGED BY INORGANIC LIGAND Wei-Ming Bu, Ling Ye, Yu-Guo Fan [1], Guo-Yu Yang, Ji-Qing Xu [2], [1] Fan, Key Lab of Superomolecular Structure and Spectroscopy, Jilin University, Changchun 130023,P.R.China, [2] Department of Chemistry, Jilin University, Changchun 130023,P.R.China

The hundreds of known examples of polyoxoanions comprise a class of inorganic complexes of unrivaled versatility and structural variation, and have application in many fields of scinece.(1)There are indications that the synthesis of polyoxometalate clusters by rational design remains elusive.(2). Utilizing molecular building blocks,the polyoxoanion family can be linked through organic or inorganic tethers to form extended structures. Zubieta et al. found that transition metal coordination compounds may function as charge compensating templates which influence the structure of the metal oxide network.(3)These observations suggested transion metal coordination compounds could act as inorganic bridging ligands. The essential element as a general method of synthesis proved to be the use of hydrothermal techniques.

The title complexes 1-3 were prepared hydrothermally employing conditions reported before. Crystal

data:$[Co(en)_3][\{Co(en)_2\}_2\ As_6V_{15}O_{42}].8H_2O$ (1): Monoclinic P2(1)/n, a=18.9133(3)A, b=19.7213(3)A, c=20.0968(4)A, beta=98.676(3) ,V=7410.23(12), z=2, R=0.0459, wR=0.0883;$[Ni(en)_2]_2\ [Ni(en)_2Mo_6V_{10}O_{40}(PO_4)].4H_2O$ (2): Monoclinc C2/c, a=26.065(2)A, b=19.730(3), c=13.485(2), beta=106.04(7), V=6664.18(10), Z=2, R=0.066; $[Cu(H_2O)_4][Cu(en)_2][\{Cu(en)(H_2O)_2Cu(en)_2\}_{0.5}\{Mo_8V_8O_{40}(MoO_4)\}].13H_2O$ (3): Orthorhombic P2(1)2(1)2, a=26.8124(4)A, b=13.6684(2)A,c=19.6058(4)A, V=7185.19(20),Z=2,R=0.048.

The compound 1 consists of infinite chains of As-V-O clusters $[As_8V_{14}O_{42}]^{6-}$ covalently linked through $[Co(en)_2]^{2+}$ groups,with isolated $[Co(en)_2]^{2+}$ cations occupying the interchain regions and providing charge compensation. The bridging Co(II) sites exhibit strong covalent interactions to the two adjacent clusters with Co-O distances of 2.091A.

The compound 2 is a Mo-V-O cluster $[Mo_6V_{10}O_{40}(PO_4)]^{4-}$ of one dimensional extended network linked through inorganic bridging ligands $[Ni(en)_2]^{2+}$. Each $[Mo_6V_{10}O_{40}(PO_4)]^{4-}$ forms strong covalent interactions to two $[Co(en)_2]^{2+}$ with Co-O distances of 2.091A.In contrast,the Ni sites of a $[Ni(en)_2Mo_6V_{10}O_{40}(PO_4)]$ cluster exhibit only weak interactions with neighboring clusters,with axial Ni...O distances of 2.98A.

The structure of 3 consists of $[Mo_8V_8O_{40}(MoO_4)]$ clusters linked by $[Cu(en)_2]$ and $Cu(en)(H_2O)_2$ groups into a two-dimensional network. Each $[Mo_8V_8O_{40}(MoO_4)]$ cluster forms strong covalent interactions to two different bridge $(Cu(en)_2]$ and $Cu(en)(H_2O)_2)$ groups with Cu-O distances of 1.901-2.025A. It is noteworthy that the structure of 1-3 exhibit hydrogen-bonding interactions between the nitrogen atoms and water molecules or terminal oxo groups of the clusters.

The title compounds 1-3 provide an intermediate prototype between polyoxoanions with surface-bound inorganic moieties and true extended polyoxoanion coordination compound assembies.Furthermore,the title compounds demonstrate that the vast class of polyoxoanion clusters may be used as building blocks in the design of solid state materials.

P13.07.002 NOVEL COORDINATION POLYMERIC NETWORKS OF COBALT(II) CENTRES WITH N,N' BIDENTATE SPACERS AND THEIR INCLUSION PROPERTIES. Mohan M. Bhadbhade, Physical Chemistry Division, National Chemical Laboratory, Pune 411 008, INDIA and E. Suresh and R. V. Jasra, Discipline of Silicate and Catalysis, Central Salt and Marine Chemicals Research Institute, Bhavnagar 364 002, INDIA

The coordination polymers, in which metal centers are linked by the organic molecules offer an enormous potential in designing new microporous materials to be used for separation, selective adsorption and catalysis as there is a wide choice of metal ions and spacers. In this paper, we report four X-ray structures having novel coordination polymeric frameworks of Co(II) with the ligands 4,4'-bipyridyl(**1, 2**) and 1,2-bis(4-pyridyl)ethane (**3**, **4**). Although the anions are different, complexes **1** and **2** are isostructural showing a novel two-dimensional network essentially governed by π…π interactions between the bpy moieties. Intertwined linear chains of $\{Co(H_2O)_2(4,4'\text{-bpy})_2$ - 4,4'-bpy$\}_n$ create micro channels of dimensions ~ 7 x 12 Å filled with molecules of 4,4'-bpy and disordered anions and waters.

Interestingly, complex **3** with a flexible linker also generates a two-dimensional architecture showing π…π interactions that creates micro channels of similar dimensions in which spacer molecules and anions are included. The flexibility of the ligand is manifested in a layered structure **4** devoid of any micro channels; the layer of Co(II) ions doubly bridged by two spacer molecules is alternated with the anionic layer. The possibility of utilizing the micro channels as in **1**(**2**) and **3** for shape selectivity of aromatic guests and for suitable catalytic reactions is being explored.

P13.07.003 X-RAY STUDY OF COMPOUNDS OF HYPERVALENT SILICON. E.A.Zelbst and A.A.Kashaev, Pedagogical University,Physic Faculty,N. Naberegnaya st.,6, Irkutsk,Russia; M.P.Demidov and M.G.Voronkov, Institute of Chemistry of Academ Nauk of Russia, Favorskogo st.,1, Irkutsk, Russia.

Winnowed full X-ray study of number of silicon-organic compounds with the total formula $X\text{-}C_6H_4C(O)YCH_2SiF_3$ (X=4-F,-Cl,-Br,2-Cl with Y=O; Y=O,S,NCH_3 with X=H) and their analogues. Discovered particularities of the crystall structure (aroiloximethyl)threefluorsilanes allow to refer these compound to the new class of representatives hypervalent silicon.

(Aroiloximethyl)threefluorsilanes exist in stable intracoordinate form, containing fivemember cycle, closed intramolekular coordination bond O-Si. Fivecoordination atom silicon in their molecules inheres in the centre an trygonal bipyramid with axyal by the location an atom of the fluorine and oxygen.

Stated that length of the communication O-Si in these molecules is changed within 1.91-2.08 A. This existance is stipulated high elektrofilates of the atom silicon, connected with three atoms of the fluorine.

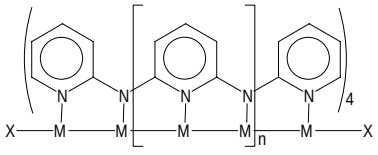
Of the Molecule (aroiloximethyl)threefluorsilanes and their analogues are bound in the crystal by power van-der-vaals. However in number of events between they exist an abbreviated intermolecular contacts.

Continuing studies of compounds of hypervalent silicon , we have defined crystall structure parameters of new compounds of this type (β-phenyl-propionyloximethyl) threefluorsilanes: $(C_6H_5CH_2CH_2COOCH_2SiF_3)$ a=7.71(1), b=6.85(2), c=10.35(2) A, β=99.78, sp.gr. $P2_1$. Expected that in this molecule is kept coordinate communication O-Si, however interfacing between five-member cycle and benzol ring, probably, lowered.

P13.07.004 MOLECULAR METALWIRES. Yih-Lih Jang, Wen-Ju Lee, Chih-Chieh Wang, Gene-Hsiang Lee, Man-kit Leung, Shie-Ming Peng, Department of Chemistry, National Taiwan University, Taipei, Taiwan

The metal string complexes with different metal ions and various lengths have been successfully synthesized and structurally characterized.[1-6]

M^{II} = Cr, Co, Ni
n = 0, 1, 2, 3



The crystal and molecular structure of nonanickel complex $[Ni_9(\mu_9\text{-}(peptea)_4Cl_2]$ which is the longest metal string at this moment will be reported. Crystal data for $[Ni_9(\mu_9\text{-}(peptea)_4Cl_2]\cdot(C_2H_4Cl_2)_{10}$: Space group, monoclinic C 2/c, a = 27.395(4), b = 42.476(9), c = 37.743(8) Å, β = 108.74(2)°, V = 41,590(13) $Å^3$, Z = 12, R_F = 8 % for the observed reflections ($I > 2\sigma(I)$).

The band structure calculation of infinite one-dimensional metal chains of Ni^{II} and Cr^{II} based on the structure of nanonickel complex will be presented. Finally, the metal string complexes $[M^{II}{}_nL_4X_2]$ will be chemsorbed on the Ag or Au surface and the potential application of these complexes as a molecular metal wire will be demonstrated.

P13.07.005 THE STRUCTURAL CHARACTERISATION OF METAL ION ACTIVATED SUPRAMOLECULAR RECEPTOR MOLECULES. Kia S. Wallwork, Christopher B. Smith, Max R. Taylor and Kevin P. Wainwright, Department of Chemistry, The Flinders University of South Australia, GPO Box 2100, Adelaide, Australia 5001.

Complexation of pendant donor macrocycles derived from cyclen (1,4,7,10-tetraazacyclododecane) with eight coordinate metal ions such as Cd^{2+} or Pb^{2+}, has been shown to give rise to binary complexes where all four pendant arms project in the same direction. The ligand, *S*-thphpc12 (1,4,7,10-tetrakis((*S*)-2-hydroxy-3-phenoxypropyl)-1,4,7,10-tetraazacyclododecane), **1**, has recently been synthesised and its coordination and host-guest chemistry is being studied. Ligands such as this are of interest for their ability to preferentially uptake cationic, anionic or neutral substrates. The subsequent system can then be used in a variety of applications, including, the transportation of radioactive isotopes to cancerous tissue.[1]

Early X-ray crystallography studies of the perchlorate salt of **1** show that the aromatic moieties delineate a molecular basket similar to that of calixarenes. Upon reaction with species such as sodium *p*-toluenesulfonate and sodium *p*-aminobenzoate, sodium perchlorate is eliminated and inclusion complexes containing *p*-toluenesulfonate or *p*-aminobenzoate can be formed.

The ternary complexes containing *p*-toluenesulfonate and *p*-aminobenzoate have been characterised. Both systems crystallise in the non-centrosymmetric space group P1, with Z=1. The guest anion is held within the host cavity via hydrogen bonding. There does not appear to be any non-bonding interaction between the ligand and the guest, in the molecular structure, but there is within the crystal structure. The characteristics, including the non-bonded inter- and intra-molecular interactions, of four of these ternary complexes will be presented and inferences will be drawn between the related compounds.

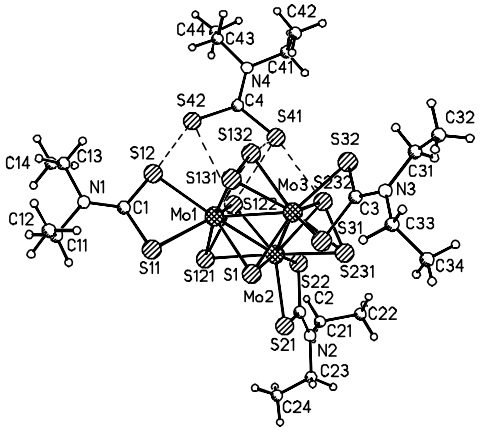
P13.07.006 SUPRAMOLECULAR ARCHITECTURE OF $Mo_3S_7dtc_4$ (dtc = DIETHYLDITHIOCARBAMATE). E.A. Il'inchik, T.M. Polyanskaya and K.G. Myakishev, Institute of Inorganic Chemistry SB RAS, Novosibirsk, 630090 Russia.

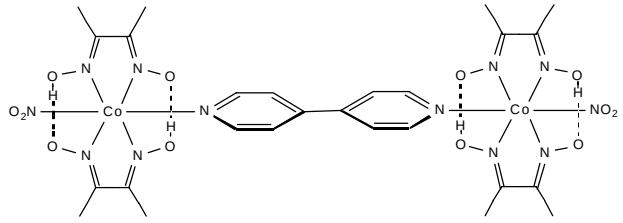
We have carried out single crystal X-ray analysis of the title compound whose structure fragment is shown below. The structure parameters of the cation core itself are closely related to those of other complexes containing the $[Mo_3S_7dtc_3]^+$ moiety. The dtc^- anion is located in such a way that its sulfur atoms have the contacts to the axial sulfur atoms of the cation μ_2S_2 ligands which are shorter than the sum of the corresponding van der Waals radii. Besides, one anion S atom has the short contact with the S atom of the next cation ligand dtc. The geometry of the anion NCS_2 fragment is distorted. The cation ligand dtc next to the anion is not planar. According to XPS, the binding energy of 2p electrons of the anion sulfur atoms, E(S2p)=161.7 eV, coincides with that for Na^+dtc^-. The sulfur atoms of the $[Mo_3S_7dtc_3]^+$ cation have E(S2p)=163.0 eV. So, all sulfur atoms of the compound have a negative charge and the short contacts take place between the same charged sulfur atoms. The Mo atoms have a positive charge that reflected by E($Mo3d_{5/2}$)=229.7 eV. The crystal data: the system is triclinic, space group $P\bar{1}$, a=10.786(2), b=11.155(1), c=16.710(3) Å, α=93.59(1), β=90.66(1), γ=100.25(1)°, Z=2, R_F=0.023.



P13.07.007 SUPRAMOLECULAR ISOMERISM IN INORGANIC COORDINATION POLYMERS. A.J. Blake, N.R. Brooks, N.R. Champness, M. Crew, D.H. Gregory, P. Hubberstey and M. Schr`der, School of Chemistry, University of Nottingham, University Park, Nottingham, NG7 2RD, UK, A.M. Deveson and D. Fenske, Institut fur Anorganische Chemie, Universitat Karlsruhe, Engesserstr. Geb-Nr. 30.45, 76128 Karlsruhe, Germany, and L.R. Hanton, Department of Chemistry, University of Otago, P.O. Box 56, Dunedin, New Zealand

The field of crystal engineering using bridging bidentate ligands with late transition metals to form co-ordination polymers, has received growing attention, with much of this work using the 4,4=-bipyridine (4,4=-bipy) ligand and its analogues. We are currently investigating the factors that affect the formation of these coordination networks. One aspect of this work is our studies into the arrays formed by CuX (X = Cl, Br, I, SCN) and bridging bipyridyl ligands. Our research into the extended polymers constructed from CuI and the bowed bipyridyl ligand bis-(4-pyridyl)disulfide (bpds) has generated a pair of supramolecular isomers. This unusual phenomenon has been seen for the polymers $[(CuI)_2(bpds)]_4$ which have a tubular structure when crystals are grown from $MeCN/CH_2Cl_2$ but a necklace motif is observed when $EtCN/CH_2Cl_2$ are used as crystallisation solvents. The different connectivities of these two compounds represents an extremely rare example of supramolecular isomerism.

P13.07.008 MOLECULAR PACKING ANALYSIS FOR MIXED CRYSTALS OF A COBALT COMPLEX. R. Wang and U. Englert, Institute of Inorganic Chemistry, RWTH Aachen, Prof.-Pirlet-Str. 1, 52074 Aachen, Germany



Complex [{Co(III)(dmgH)2(NO2)}2(4,4'-bipy)] (s. Fig.) crystallizes with a variety of small guest molecules f. e. H_2O, CH_2Cl_2, CH_3NO_2, C_6H_6, THF and so on

Different packing arrangements and the geometry of the Cobalt complex component in seven crystal structures are studied.

Lattice-energy calculation have been carried out with program PCK83[1] basing on the Atom-Atom Potential Method[2,3] for the seven crystal structures. In all seven cases the local minima from the experimental crystal structures are reproducible.

Structure:

1: Co-Complex·2 CH_2Cl_2·2C_6H_6

2: Co-Complex·2 CH_2Cl_2·2H_2O

3: Co-Complex·0.5H_2O

4: Co-Complex·2.5 CH_2Cl_2

5: Co-Complex·2 CH_3NO_2· H_2O

6: Co-Complex· CH_2Cl_2·THF

7: Co-Complex·CH_2Cl_2·CH_3COOEt

P13.07.009 β-CYCLODEXTRIN AND BUTYL/ CYCLOHEXYL (AQUA) COBALOXIME INCLUSION COMPLEXS. H.K. Fun and K.Chinnakali, X-ray Crystallography Unit, School of Physics, Universiti Sains Malaysia,11800USM, Penang, Malaysia, and Y.Chen, L.Luo and H.Chen, Coordination Chemistry Institute, State Key Laboratory of Coordination Chemistry,Nanjing University, Nanjing, 210093, P. R. China.

Cyclodextrins are a class of cyclic oligosaccharides consisting of six (α), seven (β) or eight (γ) α-1,4 linked D-glucopyranose units, with a toroidal hydrophobic cavity capable of including a variety of inorganic and organic guest species. They have been proposed to act as artificial enzymes due to their ability to form inclusion complexes and to show regiospecificity and stereospecificity with respect to the substrate and product during catalytic processing. Recently, our group synthesised a series of alkylcobaloxime/CD inclusion complexes[1,2], in which guest and host associate through non-covalent interaction, such as hydrophobic and van der Waals interactions. Here we report the crystal and molecular structures of butyl(aqua) cobaloxime (I) and its inclusion complex with β-CD (II), as well as cyclohexyl(aqua)cobaloxime (III) and its β-CD inclusion complex (IV). In (II) and (IV) , the β-cyclodextrin molecule is in the shape of a truncated heptagonal cone. In (II), the butyl group is inserted into the cyclodextrin's cavity from its wider opening such that the chain is lying below the mean plane composed of O atoms associated with the fourteen secondary OH groups. In (IV), the cyclohexyl ring is encapsulated by cyclodextrin cavity from secondary hydroxyl side and the terminal C atom lies at 2.860(5)Å below the mean plane of the secondary OH groups. The present investigations show that there are some structural and conformational changes of *n*-$C_4H_9Co(DH)_2H_2O$ after the insertion of butyl group into the β-CD cavity. That is (a) the obvious lengthening of Co-O bond and (b) the slight displacement of cobalt atom from the mean plane of four nitrogen atoms.

P13.07.010 THE SOLID-STATE STRUCTURE OF A SERIES OF DITHIINS AND RELATED SELENIUM DERIVATIVES. François Brisse, Mohamed Atfani, Jean-Yves Bergeron and Michel Armand Département de chimie, Université de Montréal, C.P. 6128, Succursale Centre-ville, Montréal, QC, H3C 3J7, Canada

Charge transfer complexes and radical cation salts derived from 1,4-dithiins and derivatives exhibit high electrical conductivity. 1,4-dithiins normally adopt the boat conformation in which the sulfur atoms are tilted towards one another. However, various molecular orbital calculations have indicated that the energy barrier between the planar and the boat conformations is very small. Thus we have investigated the structure of 1,4-dithiintetracarboxylic N,N' dimethyldiimide (1) and that of the related selenium derivative (2). The structure of 1,4-dithiintetracarboxylic N,N' di tert-butyldiimide (3) was also established. Both (1) and (2) crystallize in the monoclinic system, space group P21/n with Z=2, are isostructural. The refinements converged to R=0.038 (1) and R=0.030 (2). The tert-butyl derivative forms very thin hair-like crystals. They belong to the triclinic system. However, it seems that all the crystals that we examined are twinned, the structure was solved and R converged to 0.068 (3). It is found that all three compounds are planar. Most bond distances and angles are normal with the exception of the X-C(sp2)-C(sp2)-O distances which are significantly and systematically longer than the usual C(sp2)-C(sp2) bond distance. This observation may be attributed to the electronic repulsion between the lone pair of the heteroatom, X, and that of the the oxygen atom. The crystals are very colorful, in solution or in the solid-state. Their physical properties will be discussed in terms of packing. The crystal structures of other members of the series, where the methyl group is replaced by hexyl, decyl or phenyl groups, will be presented.

08. CRYSTAL ENGINEERING

P11.08.001 THE USE OF KETO CARBOXYLIC ACIDS AS A MODEL SYSTEM FOR CRYSTAL STRUCTURE PREDICTION. A. P. J. Brunskill, R. A. Lalancette and H. W. Thompson. Rutgers University, Department of Chemistry, 73 Warren St., Newark, NJ 07102, USA.

The dominance of hydrogen bonding in directing molecular association in crystals has long been recognized. The carboxylic acid dimer in particular has been viewed as a robust "molecular synthon". However as other hydrogen bond acceptors are added to a molecule it has been found that other H-bonding motifs are often preferred. Organic keto carboxylic acids provide a useful model system to study factors that cause variation in hydrogen bonding patterns when competing H-bond acceptors have similar electronegativities. We have synthesized and determined the solid state structures of over 50 keto carboxylic acids of varying topology, size and chirality. Many others have been found in a survey of the CSD. To date 5 distinct hydrogen bonding patterns have been found: acid-to-acid dimers, acid-to-ketone catemers (infinite chains), internal H bonds, acid-to-acid catemers and acid-to-ketone dimers. Observation of the characteristics for molecules falling into each hydrogen bonding category suggest definite methods to direct H bonding, such as control of handedness, structural rigidity and shape. By employing these design methods we have been able to produce molecules in which we have successfully directed H-bonding.

Knowledge of probable H-bonding association, combined with strict symmetry constraints and the high probability of close packing reduces considerably the number of structures that need to be considered as potential crystal structures. In effect, large parts of the energy hypersurface can be neglected, considerably reducing the computational complexity of ab initio crystal structures prediction.

Results of our experimental work and crystal structure prediction methodology will be presented.

P11.08.002 INTRAMOLECULAR NON-BONDING INTERACTIONS BETWEEN HALOGEN AND OXYGEN. G. Punte and G. Echeverría, LANADI-PROFIMO, Departamento de Física, Facultad de Ciencias Exactas, Universidad Nacional de La Plata, C.C. 67 (1900) La Plata, Argentina, A. E. Goeta, Chemistry Department, Durham University, Durham DH1 3LE, UK and J. Ellena, Instituto de Física de Saõ Carlos, USP, Saõ Carlos, SP, Brasil, A. Rubert, Departamento de Química, Facultad de Ciencias Exactas, UNLP, calles 47 y 115 (1900) La Plata, Argentina, G. P. Romanelli and J. C. Autino, LADECOR, Departamento de Química, Facultad de Ciencias Exactas, UNLP, calles 47 y 115 (1900) La Plata, Argentina

The role and nature of weak non-bonded interactions in the conformation and aggregation of organic molecules is the subject of numerous experimental investigations, extensive data base searches and quantum mechanical calculations. This is due to its importance in material engineering. From the analysis, performed on several compounds presenting differently substituted halogen-C-C-oxygen moiety/ies located in dissimilar molecular environments, we have found a tendency in these fragments to establish intramolecular halogen···oxygen short contacts. Moreover, we have shown that a short Br···O intramolecular interaction allows explaining the very good reaction yields in a novel synthesis of substituted 3-aryloxypropionitriles [1]. In this paper we go deeper in the examination of those interactions by means of different experimental techniques complemented with theoretical calculations.

P11.08.003 SUPRAMOLECULAR ASSEMBLY OF HYDROPHOBIC DIPEPTIDES INTO MOLECULAR HONEYCOMB PATTERNS Gorbitz, C. H. Department of Chemistry, University of Oslo, N-0315 Oslo, Norway

Dipeptides with two hydrophobic residues (hydrophobic dipeptides) can form layered structures in which the hydroxyl group of cocrystallized alcohol molecules constitute an integrate part of the hydrogen bond pattern.[1] Some of these dipeptides, however, form honeycomb patterns by hydrogen bonding of six molecules around hexagonal crystallographic axes in the P65 space group. The hydrogen bonding pattern is invariant, but the diameter of the resulting empty central channel is inversely related to the size of the amino acid side chains lining the hydrophobic inner surface. Accordingly, the types of molecules which can be accommodated as guests vary with the dipeptide composition. Previously the structure of L-Val-L-Ala has been presented.[2] We now report the crystal structures of L-Val-L-Val and L-Ile-L-Ala together with preliminary theoretical and experimental results for several other compounds.The aim of this study is to design structures which will absorb only one or a few types of guest molecules with high specificity.

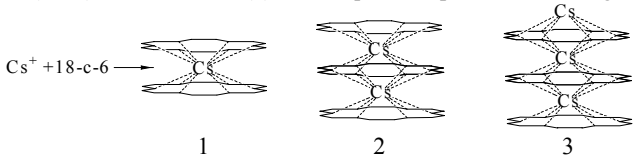
P11.08.004 EXTENDED MULTIDECKER SANDWICH ARCHITEC-TURE OF THE Cs^+ - 18-CROWN-6 COMPLEXES. J.A. Rusanova, K.V. Domasevitch, O.Yu. Vassilyeva, V.N. Kokozay, Chemistry Dpt., Kiev Shevchenko University, Volodimirska St. 64, Kiev 252033,Ukraine, J. Sieler, WB Anorganische Chemie, Universität Leipzig, Deutschland;P.J. Squattrito, Chemistry Dpt., Central Michigan University, Mt. Pleasant, USA ; P. Raithby, Chemistry Dpt., Cambrige, UK

An approach to synthesis of the triple-decker club sandwiches, in particular $Cs_2(18c6)_3^{2+}$, can be based on the observation that the large cations tend to be stabilized by large anions and *vice versa*. The suitable systems in this context are iodocuprates(I), the typical feature of which is the formation of high-nuclearity low-nucleophilicity $Cu_nI_m^{(m-n)-}$ anionic clusters. We have isolated three different iodocuprate(I) species employing zerovalent copper, 18c6, CsI and NH_4I as starting materials. $Cs(18c6)_2Cu_5I_6{\cdot}2MeCN$ (1) is a unique example for such a large



1 2 3

multidecker club sandwich, free from disorder or extremely high anisotropy in the thermal motion of the atoms. $Cs_2(18c6)_3Cu_8I_{10}{\cdot}2MeCN$ (2) is built up from the novel finite iodocuprate(I) $[Cu_8I_{10}(MeCN)_2]^{2-}$ and cations $Cs_2(18c6)_3^{2+}$, while $Cs_9(18c6)_9Cu_{24}I_{33}$ (3) includes iodocuprate(I) clusters $[Cu_4I_7]^{3-}$, $[Cu_7I_{10}]^{3-}$, $[Cu_{13}I_{14}]^{-}$, iodide anions and the 3:3 club sandwich $Cs_3(18c6)_3^{3+}$. The novel unit $[Cu_{13}I_{14}]^{-}$ is the largest finite iodocuprate(I), it has a perfect nearly spherical structure, in which 12 copper atoms are arranged in a truncated tetrahedron centered by the 13th copper atom (Cu-I 2.53(2)-3.098(6) Å). Thus in the light of the present work and our report [1], formation of the club sandwiches $Cs_n(18c6)_3^{n+}$ should be considered as a general feature of a 18-crown-6 chemistry.

K.V. Domasevitch, et al., J. Chem. Soc., Dalton Trans., 1997, 1177.

P11.08.005 INTER-MOLECULAR INTERACTIONS IN P-BLOCK CHEMISTRY: TOWARDS CRYSTAL ENGINEERING BASED ON SECONDARY BONDING. Jonathan Starbuck and A. Guy Orpen, School of Chemistry, University of Bristol, Cantock's Close, Bristol, BS8 1TS, UK.

'Crystal engineering' – the design and synthesis of the crystalline phase of molecular solids – is a field that is attracting the attention of chemists from a broad range of fields. In this work, individual molecular species have been synthesised and the broad range of structures present in the Cambridge Structural Database (CSD)[1] have been surveyed to determine the way in which popular inter-molecular interactions build into structure-forming packing motifs.

The initial systems chosen for study were those containing the bismuth (Bi) or antimony (Sb) halide moiety. The electronegativity difference that exists between Bi/Sb and halides results in polar covalent bonds leading to a tendency to form bridging interactions in the solid state. The E:::X inter-molecular interaction was originally defined by Alcock[2] as a 'secondary bond'. These interactions have been observed to play a vital role in the aggregation of molecular species centred on the heavier p-block elements.

The topology of hydrogen bonding networks has been described using 'graph-set analysis', a technique principally developed by Etter, Bernstein, Davis and co-workers.[3] These techniques have been applied to inorganic systems in an attempt to describe the topology of the interactions in a systematic and informative way.

P11.08.006 POLYIODIDE NETWORKS IN CRYSTALS. Ian Dance, Louise Berben, Basem Ali, Marcia Scudder and Don Craig, School of Chemistry, University of New South Wales, Sydney 2052, Australia.

A series of crystals containing polyiodide anions with $[Fe(phen)3]^{2+}$ cations will be presented. A significant result is the variety of polyiodide networks which can be formed with the same cation. The crystal supramolecularity of this class of compounds will be presented, and the reasons for the diversity of structure type investigated. The four types of intermolecular motif recognised in these crystals are the the multiple aryl embraces which provide attraction between $[Fe(phen)_3]^{2+}$ cations, I•••I attractions, η^6-C•••I, and C–H•••I hydrogen bonds. The polyiodide networks are one-, two- and three-dimensional. Intermolecular energies have been calculated. Polyiodide chains fit well between and around the aryl rings of the embracing cations. The ability to predict and control the structures of crystals containing polyiodide anions with cations of this type will be considered, together with the implications for crystal engineering.

P11.08.007 PHENYL EMBRACES IN THE CRYSTAL SUPRAMOLECULARITY OF COMPOUNDS CONTAING PHS–, PH4P+, XPH3 AND SN . Basem F. Ali, Ian G. Dance, Marcia L. Scudder and Don C. Craig [1] [1] Department of Inorganic and Nuclear Chemistry, University of New South Wales, Sydney 2052, Australia

The crystal supramolecularity of two classes of compounds containing sulfur are reported: Ph3X(S)nXPh3 (X = C, Si, Ge; n = 1–6) and the dimorphs of (Ph4P)2[Cd2(SPh)6] (Ph = phenyl). In both classes of crystal there are multiple phenyl embraces1 involving the phenyl rings on the periphery of the molecules and ions. The supramolecularity of each compounds is investigated through analysis of the crystal packing and the calculation of intermolecular energies. The crystal packing of the set of compounds Ph3X(S)nXPh3 is dominated by the attractive sixfold phenyl embraces between the XPh3 groups at the ends of the chain, while S•••S and S•••Ph interactions are lesser influences. The crystal packing in the dimorphs of (Ph4P)2[Cd2(SPh)6] involves attractive multiple phenyl embraces between Ph4P+ cations and between Ph4P+ and [Cd2(SPh)6]2– complexes. Similar intermolecular energies are calculated for the two crystals.

P11.08.008 STOICHIOMETRIC COEFFICIENTS, MULTIPLICITIES AND POSITIONS. N.L. Smirnova, Department of Geology, Moscow State University, Moscow 119899, Russia.

A.V. Shubnicov suggested to use multiplicities as stoichiometric coefficients (indices) in chemical formulas in 1922. I found all 385 possible sets of different multiplicities (*Md*) in 1989. Since each atom can occupy *x* positions with a given multiplicity each index has to be multiplied by *x*. *Different* multipliers *x* in formula form set - positional formula (*Pd*). The number of positions with the same multiplicity in all (230) *G*3 is 1 to 9 and .12 (digit number). The set 0, 1, 2, 12 is denoted by letter *K* and 0, 1 by *M*. All 91 *Pd* in *G*3 are given below: 1, 2, 12, (*K*)**3**, **[***K*, (*K*)3**]4**, {*K*, (*K*)3, [*K*, (*K*)3]4, [*K*, (*M*)4]6, [*M*, (*M*)4]7, [*M*, (*M*)4]8**}5**, {*K*, (*K*)3, (*M*)4, [*K*, (*M*)4]7, (*M*)8, (*M*).12, [(*M*)8].12**}6**, {*K*, (*M*)4, (*M*)8}7, {*M*, (*M*)3, [*M*, (*M*)3]4, (*M*)9, (*M*).12**}8**, (*M*)**9**, (*M*).**12**. In A_mB_n *Pd* for A+B are given without asteriscs, for A or B with asteriscs, for A - by plus sign, for B - in *italic*: *+1*, *+2*, *+12*, **(***+0*, *+1*, *+2*, *+12***)3**, **[***+0*, *+1*, *+2*, *+12*, (*+0*, *+1*, *2*, 12)3**]4**, {*+0*, *+1*, *+2*, *+12*, (*0*, *1*, 2, 12)3, [*+0**, 1, *2*, 12, (1, 2, 12)3]4, (*0*, 123)6, (*0*, 1)8, (0, *1**, 123, 14, 6)9, (1, *12*, 123).10, (*0**, 24, .10).11, .14, .15, 2.21**}5**, {*+0*,*+1*,*+2*, *12*, (*0*, 1, *2*)3, [0, *2*, (1, 2)3]4, (0, 1, 12)7, (0, 2)8, 9, .10, (0, *2**, 24).11, .12, (2, 3).13, 1.14, .16, .18, .31, .33**}6**, {*+0*, *1*, *2**, 12, (*0*, 1, 2)3, (*0*, 1, 2)4, (+0, *1*, .16)8, *.16**}7, {*+0*, *+1**, *+2*, (*+0*, *2*)4, (0, 12)9, (0, *4*).12, .14, .15, 2.17, 2.10.18, .20, 1.23, .88**}8**, {*+0**, *+1**, *+2*, (0, *2*)3, (0, *1**, *2*, 12)4, (12, 14).10, .11, 2.13, .16, 2.18, 1.24**}9**, {*+0**, *+1**, *2**, *12*, (*0*, *1*, 12, 13)4, (0, 1).12, *.18*, .21**}.10**, {*0**, *+1**, *2**, 3, 4, 12.12**}.11**, {*+0*, +1*, *2**, 3, 4, 12.14, .18, .24**}.12**, {*0**,*+2**, *3**, 14, 12.34**}.13**, {*+0**, *+1**, *2**, 4, .20, 12.34**}.14**, {*0**, +1*, 12.16**}.15**, {*0**, *2***}.16**, ***.17****, {*+0**, .33**}.18**, {*+0**, .26**}.20**, {*0**, *2***}.21**, {*1**, +2*, 2.26**}.23**, {*+0**, *1**, .36, .44**}.24**, {*0**, *2***}.26**, ***.31****, {+0*, .62**}.32**, ***.33****, *2.**34****, ***.36****, ***.44****, ***.62****, ***.88****. These sets of indices are found for thousands of compounds. The number of symbols in *Pd* is drastically reduced at the arity equal to 5. If the symbol in *Pd* is 5 or higher then the number of these symbols can be 1, 2 and very rarely 3, i.e. the parsimony law is observed.

P11.08.009 CATION DISTRIBUTIONS AND PROPERTIES OF SOME WHITLOCKITE-LIKE COMPOUNDS. A.A. Belik, B.I. Lazoryak, V.A. Morozov, and N. Khan, Department of Chemistry, Moscow State University, 119899 Moscow, Russia, and S.S. Khasanov, Institute of Solid State Physics, 142452 Chernogolovka, Russia.

Using crystal chemistry information about the structure of β-$Ca_3(PO_4)_2$ (S.G. *R*3*c*) over 130 new isotypic compounds were modeled [1] and then synthesized by solid state method: $Ca_9R(XO_4)_7$ (*R* = rare earth, Y, Bi; *X* = P, V), $Ca_8MgR(PO_4)_7$ (*R* = rare earth, Y, Bi), $Ca_{10}M(PO_4)_7$ (*M* = Li, Na, K, Cu), $Ca_9MeM(PO_4)_7$, $Ca_{9.5}Me(PO_4)_7$ (*M* = Li, Na, K; *Me* = Mg, Mn, Co, Ni, Fe, Cu, Zn), $Ca_9R(PO_4)_7$ (*R* = Fe, Cr, Ga, In, Sc, Al, Co), $Ca_9MR_{2/3}(PO_4)_7$ (*M* = Li, Na; R = rare earth), $Sr_9R(PO_4)_7$ (*R* = Fe, Cr, Ga, In, Sc), $Sr_{18}Me_3(PO_4)_{14}$ (*Me* = Cu, Co, Ni), $Sr_9MeM(PO_4)_7$

(*M*= Na. K; *Me* = Cu, Co, Ni). Crystal structures of these compounds were studied by Rietveld method. Regularities of cation distributions over five independent cation sites were found depending on cation size and charge, and total composition of whitlockite-like phase. The cation with r>0.9A occupy the $M(1)O_8$, $M(2)O_8$, and $M(3)O_8$ polyhedra, while the cation with r<0.9A occupy the $M(5)O_6$ polyhedron. Alkali cations occupy different sites along the threefold axis into the $M(4)O_{15}$ cavity. Correlation between cation distribution and unit cell parameters are made. The influence of composition on properties were studied for 1) redox reactions in $Me_9Fe(PO_4)_7$ (*Me* = Ca, Sr) and $Ca_{19}Cu_2(PO_4)_{14}$ and $Sr_{18}Cu_3(PO_4)_{14}$; 2) luminescence properties of $Ca_9MR_{2/3}(PO_4)_7$ (*M* = Li, Na; R = rare earth) and β-$Ca_3(PO_4)_2$:Eu, $Ca_9MeM(PO_4)_7$:Eu (*M* = Li, Na, K; *Me* = Ca, Mg); 3) phase transition in $Me'_9MeM(PO_4)_7$ (*Me'* = Ca, Sr; *Me* = Cu, Fe, Ni, Co, Mg; *M* = alkali cation) associated with displacement of alkali cations into the $M(4)O_{15}$ cavity of the structure.

P11.08.010 UNEXPECTED POTASSIUM DISORDER IN CRYSTAL STRUCTURES OF RHENIUM (III) THIOCHALIDE CLUSTER COMPOUNDS

S.F.Solodovnikov, S.S.Yarovoi, A.V.Virovets, V.E.Fedorov [1]
[1] Institute of Inorganic Chemistry, Russian Academy of Sciences, Novosibirsk, 630090, Russia

The single crystals of titled rhenium (III) cluster compounds (I) and (II) were prepared and their structures were studied. The both compounds are monoclinic: (I) a=9.932, b=13.528, c=12.413Å, β= 110.21°, Z=2, Sp.gr. P21/c, R=0.034; (II) a=10.614, b=17.268, c=10.448Å, b=110.75°, Z=2, Sp.gr. C2/m, R=0.042. The selected interatomic distances in (I) and (II) are Re-Re 2.586-2.597 (I) and 2.581-2.590Å (II), Re-Hal 2.550-2.574 (I) and 2.424-2.431Å (II). The separations Re-S 2.411-2.462Å in I are slightly greater compared with Re-S 2.401-2.411Å in II due to the presence of Br atoms along with sulphurs in the cluster core [Re6(S7Br)] of I. The anions [Re6S7Br7]3- and [Re6S8Cl6]4- in both structures have an layer-by-layer arrays parallel to (100) in I and (001) in II with the opposite vertices of m(3)-L8-cubes approximately perpendicular to the layer.

The most striking feature of I and II is a substantial disorder of potassium distribution over atomic positions. The K occupancies are 0.17-0.34 (I) and 0.01-0.26 (II) that being in direct dependence on the site coordination (CN =5-9 and 2-7 for I and II respectively). In I the potassium positions aggregate to form isolated tetrahedral and angle clusters whereas in II both discrete cyclic clusters (4- and 6-membered) and winding chains from vertex- and edge-linked tetrahedral clusters of K sites running along a axis are observed. The shortest distances between K positions in 'clusters' are 1.31-1.54 (I) and 0.66-1.65Å (II). Perhaps the disorder of potassium atoms results from their insufficient size to adopt large cavities between the cluster anions that makes cations to be shifted from the cavity centres and occupy 'unstable' positions. A high disorder of potassium ions in I and II make us to suggest their significant ionic conductivity (especially for II).

P11.08.011 STRUCTURAL CHANGE IN CUBIC BORON NITRIDE / DIAMOND ALLOY.

I.Ya. Nikiforov, T.P. Zhdanova, V.V. Ylyasov, Yu.V. Ilyasov. Department of Physics, Don Technical University, Gagarin Sq.1, Rostov-on-Don, 344010, Russia

The effective search of new materials with special physical properties requires the deep understanding of the laws of formation of electron structure in these materials. That is why the researches, concerning various crystalline network inhomogenities influence on the electron structure of $B_xN_yC_z$, might be of considerable interest now. Different physical properties of compounds are essentially affected by crystalline network defects. The calculations were performed for the systems $BN_{1-x}C_x$ and $B_{1-x}NC_x$ (x=0.25); with zink-blend lattice, where the C atoms substituted the B(N) atoms in a regular way (Fig.1).

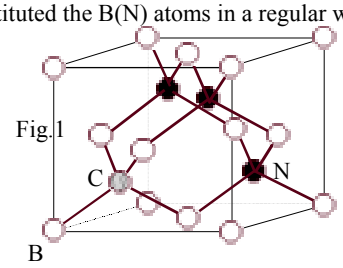

Fig.1

The crystalline potential was constructed as standard muffin-tin, including Coulomb, exchange (Slater's version) and Madelung contributions involving 15 coordination spheres[1]. Each type of chemical elements represented in the lattice corresponded to a muffin-tin sphere of its own type, using which the calculations of the energy-dependent single-site matrces $t_l(E)$ were undertaken. The lattice parameters of the solid solutions were determined according to Vegard's rule. Fig.2 demonstrates the total densities of states (TDOS) in 3-component systems $BN_{1-x}C_x$ ($B_{1-x}NC_x$), x=0.25; TDOS of binary c-BN is shown for comparison as well. The increase of the valence band top width in studied compounds is probably caused by a high degree of *s-p*-hybridization of B, N and C, the electronic states delocalization (the most evident on D-peaks) accompanied by the band displacement towards the higher energies. The displacement is maximal for $B_{0.75}NC_{0.25}$ and reaches 0.2Ry. It is interesting to notice that the peaks in the case of N-C substitution and those in the case of N-O substitution are displaced to the same side comparatively to the corresponding peaks of pure N [2]. In our opinion, it means the displacement to depend on the modulus of the difference between the electron numbers in substituted and binar compounds. So, if the element is substituted by that of the group situated to the left from its own, we suppose scattering on the "hole", otherwise - scattering on the electron.

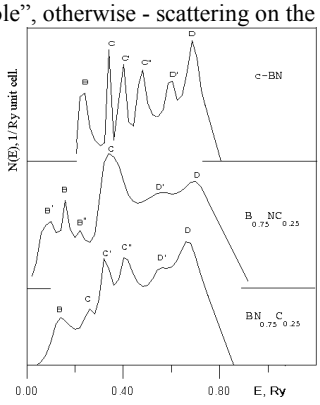

Figure 2

The estimated valence partial electron numbers following conclussions about the properties of the electron structure:

To the cubic boron nitride / diamond having a place the different types of admixture influence on the electronic distribution. In the case, when boron is substituted the energy gap decreases, evidently, owing to the covalent directed bonds per atom decrease, that leads to the lower chemical cohesive energy comparitively to binar *c*-BN. In the case of the nitrogen substitution the energy gap increases.

For the system $B_{1-x}NC_x$ (x = 0.25) electronic change transfer (0.19) from nitrogen to boron takes place. The carbon plays the role of the donor for the electronic configurations of B and N.

P11.08.012 π–STACKED COORDINATION FRAME-WORKS FORMED FROM ASSEMBLY OF BINUCLEAR METAL SQUARATE INFINITE CHAINS. Kuan-Jiuh Lin, Institute of Chemistry, Academia Sinica, Nankang, Taipei, Taiwan, ROC

Crystalline inorganic materials such as aluminosilicates (zeolites), aluminophsphates, pillared clays, and other layers are widely used in catalyst and in separation applications. Recently, crystal engineering of coordination polymers and organic networks sustained by coordinate covalent bonds and directional noncovalent interactions has become a rapidly expanding field. However, a major challenge in the relational design of highly porous organic or coordination materials is their fragility. Unlike zeolites held together with rugged covalent bonds, their solid molecules are glued with relatively weak intermolecular forces. Encouraged by our success in using squarate ligand as a robust, rigid tether for the construction of extended solids under hydrothermal conditions [1], we have turned our attention to introduce noncovalent π-π interactions in the metal squarate phases to generate new classes of coordination zeolites with hydrophilic and hydrophobic characteristics. In this report, we describe our exploratory synthesis using hydrothermal methods and structures of two novel coordination polymer, $[(FeCl)_2(C_4O_4)(phen)_2]_n$ **1** and $[(VO)_2(OH)_2(C_4O_4)(phen)_2{\cdot}H_2O]_n$ **2,** where engineering is achieved both by changes in the length of various coordination modes of squarate and by the use of highly directional π-π interactions of phen rings.

P11.08.013 ROLES OF GUEST MOLECULES IN DECAVANADATE CRYSTALS. S. Nakamura, T. Ozeki, Department of Chemistry and Materials Science, Tokyo Institute of Technology, Ookayama 2-12-1, Meguro-ku, Tokyo, Japan

Decavanadate anions, [HnV10O28]n-6, are the stable oxovanadate(V) species in acidic aqueous solution. In their tetraalkylammonium salts, we observed various molecular interactions, such as hydrogen-bonded oligomerization of protonated anions. It is a noticeable feature that the degree of protonation increases systematically as the size of the cation becomes larger. Tetra-n-propyl- and tetra-n-butylammonium cations give the closest packings. The smaller or larger cations give looser packings, leaving room for guest molecules to be included.

Our objective in this study is to investigate the roles of guest molecules in the decavanadate crystals. The term guest molecule used here refers to the solvent molecules of crystallization as well as the neutral compound like urea. This is the first step to control the molecular aggregation and crystal structure. We carried out X-ray analyses of the crystals containing urea, its alkylderivatives, and various organic solvents, each of which can function as a hydrogen bond acceptor, a hydrogen bond donor, or a dipole. Protophilic guest molecules stabilize di- or tetraprotonated monomers by hydrogen bonds. Both hydrogen bond acceptor and donor groups in the guest molecules connect to the adjacent protonated anions, to form a hydrogen-bonded chain or layer structure. Polar protophobic solvents prefer the hydrogen-bonded dimeric structures of the triprotonated anions, in the crystal of which the solvent molecules align their dipoles parallel to the electric field formed between the cations and anions. These results indicate that the electric properties of guest compounds primarily determine the aggregation patterns of the protonated decavanadate anions.

P11.08.014 VERDET CONSTANT OF TELLURIUM DIOXIDE ACOUSTO-OPTIC SINGLE CRYSTALS. A.I.Kolesnikov, R.M.Grechishkin, V.Ya.Molchanov and Yu.M.Smirnov. Tver State University, Zheliabova Str., 33, 170000 Tver, Russia

The optical activity of transparent crystals, besides being of phenomenological interest, is important to the design of acousto-optical devices because there are configurations which exploit its effect on Bragg diffracted light [1]. In the visible and in the near infrared tellurium dioxide, which is one of the most important acousto-optic crystals, is characterized by a large *natural* optical rotatory power ranging from ≈ 24 to 270 deg/mm in the interval of wavelengths from 3.4 to 0.44 μm [1]. However there is, to our knowledge, no information on the *induced* optical activity of this material which may be caused by external magnetic fields. In the present work we report the first measurements of the magnetic field effect on the Faraday rotation in tellurium dioxide single crystals of optical quality.

Large (up to 5 cm-in diameter) single crystals of optical quality were grown from the melt by Czochralsky method. Measurement of the Faraday rotation was performed for a cubic sample (10×10×10 mm) cut parallel to the crystallographic planes (001), (110) and $(1\bar{1}0)$ with optically flat (001) faces perpendicular to the laser beam to minimize the birefringence effect. Rather large values of Verdet constants (0.21 min/A at the wavelength 530 nm, 0.13 min/A at 632 nm) were measured. The dispersion of the Faraday effect is dependent upon the optical absorption bands of the material under study. The observed magnetooptic activity of paratellurite may find its use in narrow-band acousto-optical tunable filters for magnetic trimming of the spectral transmission function.

P11.08.015 CATION DISTRIBUTION OF $MgAl_2O_4$-$MgFe_2O_4$ SPINEL SOLID-SOLUTION Nakatsuka, H. Ueno, N. Nakayama and T. Mizota Department of Advanced Materials Science and Engineering, Yamaguchi University, Ube, Yamaguchi 755-8611, Japan

Single crystals of $MgAl_2O_4$-$MgFe_2O_4$ spinel solid-solution were synthesized using PbF_2 flux. Powder X-ray diffraction patterns of the synthesized single crystals show that the miscibility gap exists in the intermediate compositional range of this spinel solid-solution. Cation distribution of this solid-solution in the single phase region was investigated using single crystal X-ray diffraction method; the result shows that Al^{3+} occupies B-site (six-coordinated site) more preferentially than A-site (four-coordinated site). This cation distribution cannot be explained from the viewpoints of cation size ($r_{Al} < r_{Fe} < r_{Mg}$; Shannon [1]), because the smallest ion (Al^{3+}) preferentially occupies the larger site (B-site). On the basis of the results obtained from the structural refinements, the causes of this peculiar cation distribution and the miscibility gap will be discussed from the viewpoints of crystal chemistry.

P11.08.016 THE STRUCTURES OF METAL COMPLEXES OF THE SCHIFF BASE LIGAND DERIVED FROM 2-(2-AMINOETHYLAMINO)-ETHANOL. Ray J. Butcher and William Townes, Department of Chemistry, Howard University, Washington DC 20059

The condensation of 2-(2-aminoethylamino)ethanol with various hydroxyaldehydes and hydroxyketones results in a tetradentate ligand (X-HL, where X is the substituent on the phenyl ring and H is the phenolic proton), with an N_2O_2 donor set. Reaction of these ligands with the perchlorate salts of zinc (II), copper(II), nickel(II), and manganese(II) results in a series of complexes in which the structural requirements of the ligand and the electronic requirements of the metal are expressed in different ways. In the case of Mn(II), in the resulting complex the preformed ligand has hydrolyzed forming $[Mn(5\text{-}NO_2\text{-}salen)(CH_3OH)(H_2O)](ClO_4)$ with the manganese oxidized to Mn(III). In the case of nickel the resulting compound has Ni(II) in both 4- and 5-coordinate geometries, $[Ni(5\text{-}ClL)]^+[\ Ni(5\text{-}ClL)(CH_3OH)]^+(ClO_4)_{\ 2}$. Complimentary hydrogen bonding interactions between the deprotonated phenolic oxygen and the alcoholic proton of an adjoining complex link the 4- and 5-coordinate moieties into a ribbon. An isostructural Cu(II) complex is formed with the same ligand. With the ligand derived from 5-nitrosalicylaldehyde, on the other hand, the resulting copper complex has the stoichiometry $[Cu(5\text{-}NO_2\text{-}L)(H_2O)](ClO_4)$. The reaction of zinc with this latter ligand results in an unusual dimeric complex where the two Zn(II) ions are linked by an unprecedented five coordinate trigonal bipyramidal (angles very close to 90 and 120 degrees) $(CH_3)_2PO_3^{2-}$ moiety through oxygen. These structures will be compared and contrasted and related to both the nature of the ligand and the requirements of the metal.

P11.08.017 TRIGONAL PRISMATIC AND OCTAHEDRAL HEXAKIS(METHYLBENZENETHIO-LATO) ZIRCONATE COMPLEXES. Kristin Kirschbaum, Dean M. Giolando,* Carsten Cornelissen, Jan Friese, Han Vinh Huynh; Department of Chemistry, University of Toledo, Toledo, OH 43606 USA

Recently, the interplay of energetics between octahedral and trigonal prismatic geometry of six-coordinate complexes of transition metal has become a topic of considerable experimental and theoretical interest. Twisting of the MS_6 geometry between these two geometric limits has been attributed to several factors. While experimental and theoretical work suggests electronic factors are primarily responsible for observed coordination geometry it is difficult to deconvolute contributions made by electrostatic factors. Our studies on six-coordinate thiolate complexes began with a set of titanium complexes containing thiolate ligands exhibiting large twists away from the octahedral limit. To further explore this phenomena we synthesized monometallic complexes containing unidentate thiolates by treating $[Zr(CH_3)_6]^{2-}$ with aryl thiols. The resultant $[Zr(SC_6H_4\text{-}x\text{-}CH_3)_6]^{2-}$

($\mathbf{1}^{2-}$) complexes (x = 2{$\mathbf{1o}^{2-}$}, 3{$\mathbf{1m}^{2-}$} and 4{$\mathbf{1p}^{2-}$}) contain a nearly trigonal prismatic ZrS_6 core for x = 2 and 4, while for x = 3 the core is octahedral. In terms of electronic donating factors the 2- and the 4-position exert similar influences, which are usually distinctly different from that of the 3-position. Hence it is expected that complexes would exhibit a different coordination geometry dependent on the position of the aryl substitute. However, in the case of $SC_6H_4\text{-}x\text{-}CH_3$ the pKa values for the thiols are very similar, which suggests that the level of charge on the sulfur atoms is about the same in all three thiolates. This observation suggests that electrostatic or VSEPR contributions to the coordination geometry are not significant and that electronic factors are the principle governing influence.

P11.08.018 GENERALIZED VEGARD´S LAW. R. R. Mijangos (1), A. Cordero-Borboa (2), V. M. Castaño (2), (1) Centro de Investigación en Física, Universidad de Sonora, A. P. 5-88, 83190, Hermosillo Sonora, Mexico, (2) Instituto de Física, UNAM, A. P. 20-364, Mexico, D. F. 01000, Mexico.

We found as valid a Vegard´s law generalization. The original law gives the value for the lattice constant of a mixed alkali halide crystal with two miscible components, this law gets the form: a=a1(1-X)+a2X, being a1 and a2 the lattice constants of these components and X its molar fraction, Its validity is confirmed by X ray analysis, in crystals such as KCl(1-x):KBrx. We finding miscibility in crystals of three and four components, the generalization is carried out based in the measuring of the lattice constant by X rays diffraction of a ternary crystal KCl:KBr:RbCl (three components) with similar molar fraction (0.33:0.33:0.33)(1) and a quaternary crystal KCl:KBr:RbCl:RbBr with molar fraction (0.3:0.3:0.3:0.1); both crystals shown a single phase. The average value given by a generalized Vegard´s law of the lattice constant is encountered as valid in these crystals. The Raman spectra of the ternary crystal reveals crystallographic texture.

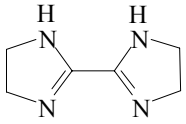
P11.08.020 CRYSTAL ENGINEERING OF IRON SPIN-TRANSITIONS. V. McKee and C. Brennan, Chemistry Department, Queen's University, Belfast BT9 5AG, Northern Ireland.



BI

Spin-transition complexes have potential application as thermal or optical switching devices [1, 2]. This requires that the transition occurs about the temperature of interest and shows hysteresis over a wide temperature range. In general terms, the presence of hysteresis can be related to the strength of interactions between individual iron centres in the lattice.

Some iron(II) and iron(III) complexes of ligand 2,2'-bi-2-imidazoline (*BI*) show spin-crossover behaviour ($^5T_2 \leftrightarrow {}^1A_1$ and $^6A1 \leftrightarrow {}^2T_2$ transitions for Fe(II) and Fe(III), respectively) [3]. The temperature and sharpness of the spin transitions are dependent on the anion present. As the anion is not directly coordinated to the iron, it is probable that the properties of the transition are controlled by H-bonding between the non-coordinated amines of BI and the anions. Consequently, the spin-transition parameters might be engineered by rational design of the lattice H-bonding.

The iron complexes are difficult to crystallise so we have combined single-crystal studies on some iron complexes of *BI* with those on other transition metal complexes and with powder diffraction methods to establish the lattice packing in a range of complexes. There is extensive isomorphism of, for example, $[M(BI)_3](X)_2$ systems provided the anions (X) have similar size and geometry (e.g. ClO_4^- and BF_4^-). The magnetic and Mössbauer properties of the iron complexes are also being studied and related to the structural data.

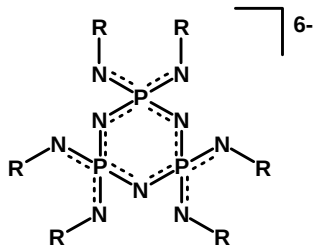
P11.08.021 MULTIANIONIC PHOSPHAZENATES. Gavin T. Lawson, Alexander Steiner, Department of Chemistry, University of Liverpool, Crown Street, Liverpool L69 7ZD, UK

Recently we have discovered the multianionic ligand system $[P_3N_3(NR)_6]^{6-}$, which is isoelectronic to the trimeric metasilicate ion $[Si_3O_9]^{6-}$, but in addition contains organic groups.[1] $[P_3N_3(NR)_6]^{6-}$ is derived from the amino substituted phosphazene $P_3N_3\{N(H)R\}_6$,which reacts as a hexaprotic acid in the presence of strong organometallic bases, such as butyllithium. Due to their multiple charge we called these systems phosphazenates.



The striking difference of phosphazenates to isoelectronic silicates is the extensive organic surface, which covers the central metal phosphazenate cores. This provides good solubility in aprotic organic solvents and facilitates organometallic chemsitry on the multiple charged system. Another distinguishing feature is the high kinetic stability of the flexible P-N-backbone, preventing ring cleavage reactions in the presence of strong nucleophiles, such as organometallic bases. In the solid state phosphazenates exist as molecular arrangements rather than showing extended polymeric lattice of silicates. On our poster we describe crystal structures of organometallic derivatives of phosphazenates.

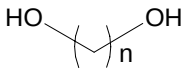
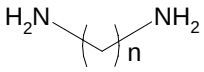
P11.08.022 THE MELTING POINT ALTERNATION IN α,ω-ALKANE DIOLS AND α,ω-ALKANE DIAMINES. Venkat R. Thalladi, Hans-Christoph Weiss and Roland Boese,* Institut für Anorganische Chemie, Universität-GH Essen, Universitätsstraße 5-7, D-45117 Essen, Germany.

It is known for a long time that *n*-alkanes show an alternation in their melting points with the even members exhibiting systematically higher melting points compared to the odd members. A logical explanation for such an alternation has been given very recently on the basis of thorough crystal structural analysis [1]. The alternation of melting points and other physical properties is also observed in several α-substituted and α,ω-disubstituted *n*-alkanes. In this connection we have determined the crystal structures of α,ω-alkane diols and α,ω-alkane diamines at low temperature.



n = 2-9



n = 2-8

The analysis of the crystal structures has revealed the interplay between hydrogen bonding and hydrophobic interactions. The rationale for the remarkable structural similarities within the series of even or odd members and the distinct differences between even and odd series is presented.

P11.08.023 CRYSTAL STRUCTURE OF THE 1-D COMPOUND $[Cu(NCS)_2bpk]_n$ (bpk=bis-2-pyridiylketone). R. Cortés[a], Z. E. Serna[b], M. K. Urtiaga[c], M. G. Barandika[a], L. Lezama[b], T. Rojo[b]. Departamentos de Química Inorgánica[a,b] y Mineralogía-Petrología[c], Facultad de Farmacia[a] y Facultad de Ciencias[b,c], Universidad del País Vasco, Apdo. 450, Vitoria-01080 SPAIN, Apdo. 644, Bilbao-48080, Spain.

High-dimensional magnetic-molecular systems can be obtained by promoting a number of vacant sites around the metal coordination sphere which can be filled by the appropriate bridging ligands. This can be carried out by combining the use of pseudohalide ions with one unit of a bidentate organic ligand. In this work, the thiocyanate and bpk ligands have been selected for the preparation of an extended system of general formula $[Cu(NCS)_2bpk]_n$.

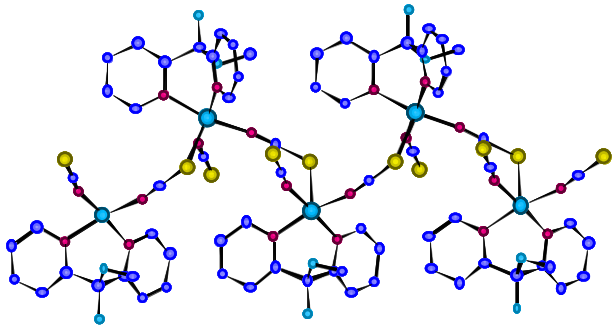

Figure 1

X-Ray single-crystal diffraction analysis revealed that the structure consists of μ-(1,3)-NCS-bridged Cu(II)-chains in which the bidentate bpk ligands and terminal NCS groups complete the copper coordination sphere (figure 1). The compound is monoclinic, $P2_1/n$, a=9.080(1) Å, b=8.942(2) Å, c=20.523(4) Å, ß=101.94(2)°, Z=4.

P11.08.024 INFLUENCE OF THE GUEST ON THE PACKING OF DIMERIC α-CYCLODEXTRIN COMPLEXES. I. M. Mavridis and S. Makedonopoulou, Institute of Physical Chemistry, N.C.S.R. "Demokritos" Aghia Paraskevi 153 10, Athens, Greece.

Packing pattern of host:guest complexes of β-cyclodextrin (βCD) are discussed. In most of βCD inclusion complexes two βCD molecules self-assemble and form a dimer which encloses one or more molecules of guest. The whole is a supermolecule held together by intermolecular non-bonding interactions. The dimer has the shape of a cylinder whose dimensions and external surface remain unchanged irrespective of the guest. The latter influences only the top and bottom faces of the cylinder where some parts of it are exposed. As a result of this influence four packing modes are encountered [1].

The study of the molecular packing of the βCD complexes in conjunction with the nature of the guest is a means towards a better understanding of the association of the supermolecular units and the way that molecules are recognized. Conversely, if we understand molecular recognition we can select appropriate building blocks that interact according to specific rules and organize into pre-designed systems that will lead to the design of crystal structures with specific characteristics.

P11.08.025 MICROSCOPIC STUDIES ON CRYSTALS OF INSULIN MUTATED AT CRYSTAL CONTACT SURFACES. U. Schell and R. Hilgenfeld, Institute of Molecular Biotechnology, Department of Structural Biology & Crystallography, Beutenbergstr. 11, 07745 Jena, Germany.

Insulins mutated at crystal contact surfaces are excellent objects to study the effects of the alterations on crystallisation conditions, crystal contacts, crystal quality and stability. The mutant DesPheB1 of porcine insulin was crystallised in the presence of Zn^{2+} and phenol, which is often added as preservative in pharmaceutical insulin preparations. It has been shown previously that phenolic compounds bind to specific sites on the insulin hexamer and act as allosteric effectors, inducing a transformation of the T_6 hexamer (in rhombohedral spacegroup R3) to the R_6 hexamer (mostly in monoclinic spacegroup $P2_1$) [1]. However, mutant DesPheB1, in the presence of phenol, exclusively crystallised in the rhombohedral spacegroup R3. This indicates that residue B1 is obviously essential for interhexameric contacts in monoclinic crystal forms. The structure of this mutant is presently under investigation. We will present preliminary results on the visualization of the crystal faces by atomic force microscopy which has been used only recently to detect packing defects at near molecular resolution [2]. A novel high-magnification stereo-microscope constructed in our department is used to follow crystal growth.

P11.08.026 ATTRACTIVE INTERACTIONS IN TWO NOVEL PERI-NAPHTHALENE DERIVATIVES. Jane O'Leary, Wolfgang Skranc and John Wallis, Centre for Materials Research, School of Physical Sciences, University of Kent, Canterbury, England.

Phenylisocyanate reacts with 8-lithio-1-dimethylaminonaphthalene to give a novel 2:1 product along with the expected 1:1 anilide. The former contains a H-bonded six-membered cyclic system, not represented in the current CSD, the (N-)H---O distance being 1.86 Å with a NHO angle of 141°. In both structures the dimethylamino group has pyramidal geometry and the nitrogen atom's lone pair of electrons is directed towards the carbonyl carbon of the second substituent. Both structures contain peri N----C=O interactions, with N----C distances of 2.619(2)Å and 2.647(2)Å and small pyramidalisation (+0.053(1)Å and +0.046(2)Å) at the carbonyl groups, similar to those represented in other systems [1].

P11.08.027 C-H...O HYDROGEN BONDS OBSERVED BY X-RAY DIFRACTION IN BISIMINE SELF MOLECULAR ASSEMBLY. A. Reyes-A., J. Nájera-M., H. Salgado-Z. and J. Tamariz-M. Departamento de Química Orgánica. Escuela Nacional de Ciencias Biológicas, IPN. Carpio y Plan de Ayala S/N. Colonia Santo Tomás. 11340 México D. F.

Intermolecular C-H...O contacts [1] in the self-molecular assembly of bis(4-nitrobenzylidene)ethylenediamine have been observed by X-ray crystallographic studies.

The non-formation of a supramolecule between the above mentioned bisimine with either hydroquinone or meso-1,2-diphenyl-1,2-ethanediol (meso-hydrobenzoin) suggests that these unique C-H...O non-bonding interactions should be of considerable strenght to favour the self-assembly process.

The poor solubility of the compound in most organic solvents might be explained in similar terms.

P11.08.029 STRUCTURES OF TWO NEW NICKEL 42-OXO- DODECATUNGSTATES. Z.Žák and J.Taraba, Department of Inorganic Chemistry, Masaryk University, Brno, Czech Republic.

The chemistry of polynuclear oxometalate anions, polyoxometalates, have attracted much attention recently[1]. There have been many polytungstates of alkaline metals synthetized and their structures determined [2] but only very few containing transition metal cations are known. Recently, we have published syntheses and structure determinations of two cobalt 42-oxododecatungstates, one of them being one of the very few containing only a transition metal cation [3]. Now, we have succeeded in the synthesis and structure determination of another example of transition metal paratungtates, $[Ni_5(H_2O)_{22}][H_2W_{12}O_{42}].16H_2O$ (NIWOL) and $[Ni_3Na(H_2O)_{16}][H_3(H_2W_{12}O_{42})].18H_2O$ (NIWL). The structures are built from $H_2W_{12}O_{42}^{10-}$ anions joined by cations into three-dimensional networks. The $H_2W_{12}O_{42}^{10-}$ cage in NIWL is situated on a symmetry center, while that of NIWOL lies in a general position. The figure depicts "molecules" of both compounds in a polyhedral representation including symmetry related Ni-O_6 (crossed) and Na-O_6 (blank) octahedra.

Grant GACR no. 203/98/0676 is gratefully acknowledged.

P11.08.030 STRUCTURAL ANALYSIS OF THE 2-D COMPOUND $[Mn(N_3)_2bpa]_n$ (bpa=1,2-bis(4-pyridiyl)ethane). M. G. Barandika[a], M. L. Hernández-Pino[b], M. K. Urtiaga[c], R. Cortés[a], L. Lezama[b], M. Arriortua[c]. Departamentos de Química Inorgánica[a,b] y Mineralogía-Petrología[c], Facultad de Farmacia[a] y Facultad de Ciencias[b,c], Universidad del País Vasco, Apdo. 450, Vitoria-01080 SPAIN, Apdo. 644, Bilbao-48080, Spain.

High-magnetic-ordering systems based on transition-metal supramolecular arrays can be obtained by enhancing the linking of smaller structural units. This can be carried out by combining the use of pseudohalide ligands with N,N' bidentated organic spacers. In this work, the azide and bpa (bpa=1,2-bis(4-pyridyl)ethane) ligands have been selected for the preparation of an extended system of general formula $[Mn(N_3)_2bpa]_n$.

X-Ray single-crystal diffrac-tion analysis revealed that the structure consists of di-μ-(1,3)-N3-bridged Mn(II)-chains which are linked by bpa ligands resulting in a 2D arrangement (figure 1). The compound is monoclinic, C2/c, a = 9.991(3) Å, b = 13.883(2) Å, c = 10.482(3) Å, ß=103.15(2)°, Z=4).

P05.09.001 LONSDALITE MONOCRYSTAL - THE SOLID PART OF THE EARTH KERNEL. R.V.Galiulin, Institute of Crystallography Russian Academy of Scieces, Moscow 117333 Leninsky Prospect 59

They say that Kathleen Lonsdale was very sorry that the big crystals of lonsdalite was not found. Apparently unique place for this crystals is the Earth Kernel (the temperature is 3000 grad., the preasure is 3500 kilobars) where it can grow from a carbon solution in a ferric melt as a dendrite crystal. In Mantle this crystals continue to grow as a diamond. Some of it branches burns out (heating the Earth) and through volcanoes will be rejected on a surface of the Earth where they using solar energy catching by the plants and turn into the coal. The last one turns to graphite (nets of which are two dimensional Euclidean diamond crystals [1]). Graphite turns in- to the diamond and last one reaching The Mantle turns into the lonsdalite. In this process take part all crystal modifications of carbon - soot (zerodimensional diamond - orbifold, and one-dimensional spherical diamonds), fulerenes (two-dimensional spherical diamonds), quasicrystals of carbon with fivefold and seven-fold symmetry (hyperbolic's diamonds). Some other elements take part in trans- porting solar heat to the Kernel too [2]. It is possible because of nonlinearity of the laws of motions of atoms [3] the attractor of which are solid part of the Earth Kernel.

P05.09.002 ICE TEMPERATURE EFFECT ON PROTON-ORDERED ARRANGEMENT IN ANTARCTIC ICE. Hiroshi Fukazawa, Shinji Mae, Department of Applied Physics, Faculty of Engineering, Hokkaido University, N13 W8, Sapporo 060-8628, Japan. Susumu Ikeda, Institute of Materials Structure Science, High Energy Accelerator Research Organization (KEK), Oho 1-1, Tsukuba, Ibaraki 305, Japan

Analysis of the Raman spectra of Antarctic ice showed that a second-order phase transition from the proton-disordered phase to a proton-ordered phase takes place at T_i = 237 K (T_i; ice temperature in the ice sheet) in the Antarctic ice sheet [1]. We measured the neutron scattering of ice recovered from Antarctic ice sheet. From the scattering spectra, we calculated the T_i dependence of the order parameter (the ratio of ordered protons in ice), which is consistent with the theory of the order-disorder phase-transition from proton arrangements in ordinary ice to proton-ordered arrangements at T_i = 237 K. The results indicate that Antarctic ice in which $T_i \leq 237$ K (about one third of the Antarctic ice mass) contains proton-ordered arrangements.

P05.09.003 CRYSTAL STRUCTURE OF $NaLiMnP_2O_7$ G.S. Gopalakrishna, Department of Studies in Geology, University of Mysore, Mysore 570006, INDIA and M.A. Sridhar and J. Shashidhara Prasad, Department of Studies in Physics, University of Mysore, Mysore 570006, INDIA

The study of Sodium Superionic Conductors has become popular particularly, after the development of NASICON groups of fast ionic conductors. Manifold variations by suitable substitutions to these compounds have led to the development of many new solid electrolytes. These fast ionic conductors still pose challenges to material scientists in growth and characterization because of their polycrystallinity, non-stoichiometric composition and complex conduction mechanism. NASICON or its analogues always have only the triorthophosphate end members and their structures were directly related to $Na_3Sc_2P_3O_{12}$. The title compound is a new phosphate compound which is a prospective fast ionic conductor. $(Na_2LiMnP_2O_7)_2$ crystals were synthesised by hydrothermal technique at relatively low temperature and pressure. The title compound, a nasicon analogue, crystallises in the triclinic space group $P\bar{1}$ with a = 6.657(3)Å, b = 6.714(6)Å, c = 6.518(4)Å, α = 112.31(6)°, β = 92.14(4)°, γ = 83.89(5)° and Z = 2. The structure was solved using SIR92 [1] and refined using teXsan [2]. The final residual is R = 0.064 for 923 reflections with $I > 3\sigma(I)$. The refinement was carried out by treating all oxygen atoms as isotropic and the rest as anisotropic. The procedure is similar to structure solution of similar compounds reported earlier [3,4].

P05.09.004 A NOVEL FAMILY OF LAYERED BISMUTH COMPOUNDS. D.O.Charkin, P.S.Berdonosov, and V.A.Dolgikh, Dept. of Chemistry, Moscow State University, Moscow 119899 Russia; P.Lightfoot, School of Chemistry, University of St.Andrews, St.Andrews, FIFE, United Kingdom

Multinary Bi, Ln (An) oxides, oxide halogenides, chalcogenides, etc. constitute a large family of compounds which exhibit unusual crystal structures and prospective physical properties. Many of them possess layered structures with fluorite-related positively charged layers separated by negatively charged ones derived from different structural types. Some of the compounds are known as ionic conductors, ferroelectrics, HT superconductors, etc. In particular, oxide halogenides are interesting as possible ferroelectrics and oxidation catalysts. In their structures, fluorite-related layers are separated by either halogenide ion sheets, or NaCl-type layers. There is hitherto a unique intergrowth structure, where CsCl-related anionic layers also can be met together with single $[Cl^-]$ anion sheets [1].

We have modelled and synthesized a series of 20 novel multinary Bi oxyhalides. In their crystal structure, fluorite-related layers are separated either only by CsCl-related layers (type A), or alternatively by CsCl-type layers and double $[Cl^-]$ sheets (type B). The crystal structure of $Pb_{0.3}Cs_{0.3}Bi_{0.7}OCl$ (type A) was solved from powder data ($I4/mmm$, Z=4, R_p=0.063, R_{wp}=0.081), while the structure of $Pb_{0.15}Cs_{0.15}Bi_{0.85}OCl$ (type B) was solved from single crystal data ($I4/mmm$, Z=8, R=0.08, R_w=0.11). In the fluorite-related layers, Bi^{3+} ions can be substituted, besides Ca^{2+}, by Pb^{2+}, Na^+, Sr^{2+}, and Ba^{2+}, similar to that in the so-called Sillén phases. The CsCl-related layers can contain also Rb^+ and Br^-; the a cell parameters are almost insensitive to replacement of Cs^+ by Rb^+ in the cubic voids. Differences and similarities in crystal chemistry of the novel compounds and related ones containing the same fluorite-type layers are analyzed. A general classification of crystal structures with the fluorite-like and anti-fluorite-like layers is given.

P05.09.005 ON PENTAIODIDES. K.-F. Tebbe and I. Pantenburg, Institut für Anorganische Chemie der Universität zu Köln. Greinstraße 6, D-50939 Köln, Germany.

A special property of polyiodides is the variability regarding their composition and structure [1]. Addition rules for one (I^-) and two (I_2) units lead to the formula I_x^- with x = 1 + 2i + 2k/l describing all possible definite compositions. The structures of polyiodide units in crystalline solids are characterized by fluctuation of distances and angles, connectivity (coordination number) and dimensionality. Distances range from the value for the iodine molecule (≈270 pm) to the van der Waals contact (≈ 430 pm) with pronounced accumulations for essential structural motifs, e.g. elongated iodine molecules I_2 (≈ 275 pm), symmetric (≈ 292 pm) and asymmetrical triiodide ions I_3^- (280 to 315 pm), close contacts between iodine molecules I_2 and iodide ions I^- or triiodide ions I_3^- (≈ 320 pm), between two iodine molecules (≈ 340 pm) or between two triiodide ions (≈ 360 pm) and short van der Waals type contacts (> 370 pm). Most angles are distributed around 90 ^{o} and 180 ^{o} even for the longer distances. The connectivity may range from 1 to 6, the dimensionality from 0 to 3. The preference of the angles leads to the concept of orthogonal lattices $^n_\infty(I^-nI_2)$ and their fragments [2]. Pentaiodides I_5^- are suitable to demonstrate such concepts because they separate compounds I_x^- with lower (x < 5) from those with higher (x > 5) iodine contents [3]. Fourfold connected nets $^n_\infty[I^-4(I_2)_{1/2}]$ with iodide ions I^- in the knots and iodine molecules I_2 on the connecting lines have the composition of pentaiodides. In particular the infinite planar checkered (4,4)-net fulfills in addition the condition of orthogonality. This may be riped up (by the cations) into chains of different kind and at least into the isolated V-shaped anion. Most of the observed structures (≈ 50) have been classified within such a scheme. One example may be derived from the diamond net.

P05.09.006 A PAIR OF BISMUTH TANTALALUM OXIDES WITH 'BLOCK-DISLOCATION' MODULATED FLUORITE-TYPE STRUCTURES. C.D. Ling, J.G. Thompson, R.L. Withers and S. Schmid, Research School of Chemistry, Australian National University, Canberra, ACT 0200, Australia.

The high-temperature phase of bismuth oxide (δ-Bi_2O_3) is one of the best oxygen ion conductor known. It cannot, however, be quenched to room temperature. Bismuth-rich phases in ternary oxide systems involving certain transition metal oxides appear to approximately preserve both the fluorite-type structure and ionic conduction properties. $Bi_7Ta_3O_{18}$ and $Bi_4Ta_2O_{11}$ were previously described in this context as superstructures of fluorite-type [1].

During an extensive reinvestigation [2] we found the unit cells reported for $Bi_7Ta_3O_{18}$ and $Bi_4Ta_2O_{11}$, based on superstructures of fluorite-type, to be incorrect. Using the correct cell we were able to solve the *P*1 (pseudo-*C*2/*m*) structure of $Bi_7Ta_3O_{18}$ using single-crystal synchrotron X-ray data [3]. By comparing unit cells, compositions and symmetries, an unambiguous $P\bar{1}$ model for the structure of $Bi_4Ta_2O_{11}$ could be derived from that of $Bi_7Ta_3O_{18}$. This model was successfully Rietveld-refined using synchrotron XRD and powder neutron diffraction data [4]. Both structures are fully ordered, with columns of TaO_6 octahedra and variously coordinated Bi^{3+} ions. The metal atom arrays approximate fluorite-type with regular 'block-dislocation' defects perpendicular to $[1\,1\,1]_f$. This structural motif is responsible for confusing electron diffraction and XRD patterns, on the basis of which they were originally mis-indexed as simple superstructures of fluorite-type.

P05.09.007 QUANTITATIVE WIDE ANGLE CBED APPLIED TO NON-STOICHIOMETRIC RARE-EARTH ZIRCONATE PYROCHLORES. Y. Tabira and R. L. Withers, Research School of Chemistry, Australian National University, Canberra,A.C.T.0200

The crystal structure of a wide range non-stoichiometric samarium zirconate pyrochlore has been investigated as a function of composition using a Wide-Angle Convergent Beam Electron Diffraction (WACBED) technique. Systematic changes in the one unknown oxygen atom fractional co-ordinate are found as a function of composition.

Solid solutions $Ln_yZr_{1-y}O_{2-y/2}$ have the pyrochlore structure for rare earths from *Ln* = La to Gd. In the ideal pyrochlore structure (corresponding to y = 0.5), there is only one unknown oxygen atom fractional co-ordinate. No structural models for off-stoichiometric composition have to date been reported. The exact extent of the various solid solutions as a function of rare earth ion has yet to be determined.

Cell dimensions as a function of chemical composition show a very narrow (less than 2 mole % in full width) solid solution (ss) field for the $LaO_{1.5}$-ZrO_2 pyrochlore system which increases systematically to 18 mole % in full width for the $SmO_{1.5}$-ZrO_2 pyrochlore system (from 37.5 mole % $SmO_{1.5}$ to 55 mole % $SmO_{1.5}$). The dependence of the width of the pyrochlore solid solution field upon the rare earth ion is attributed to the ionic size difference between Ln^{3+} and Zr^{4+}.

The WACBED technique can be applied to small irradiated areas and is quite sensitive to the position of light atom species (such as oxygen atoms in heavy metal oxides)[1-2]. The unknown oxygen atom fractional co-ordinate x is found to be about 0.352 in the case of the 40 mole % $SmO_{1.5}$ specimen which is significantly larger than that (x = 0.343) found for the stoichiometric 50 mole % $SmO_{1.5}$ specimen. The increased x value is consistent with a systematic shift towards the defect fluorite structure, which appears on both sides of the relevant ss field.

P05.09.008 STRUCTURAL SERIES IN COMPLEX CUPRATES. V.Maltsev[1], L.Leonyuk[1], G.-J.Babonas[2] [1] Department of Geology, Moscow State University, Moscow 119899, Russia [2] Semiconductor Physics Institute, Vilnius LT-2600, Lithuania

The series of compounds in the family of complex cuprates were distinguished in order to reveal the generic relationship [1] between the structures and to emphasise the characteristic structural features. In the fragment approximation various combinations of different blocks can be distinguished in the compounds which are grouped into the *plesiotypic, merotypic, polytypic or polysomatic* series of structures [2, 3]. The terms characterise the relationship between the structures which constitute a particular series. In a great variety of cuprate structures various groups of compounds are expected to form the series of a different type. The structures of several cuprate groups are considered. The polysomatic and other type series are distinguished in order to reveal the general regularities in the structures of complex cuprates.

Layered cuprates with CuO_2-planes : The compounds in the Ba-Ca-Cu-O system can be considered as *polytypic* series, into

which Y(Ca)$Ba_2Cu_3O_x$ can be included taking into account a possible substitution Y↔Ca. The Bi-2212-type compound can be regarded as the polysome *AB* of the chemical composition $(Bi_2O_{3-x})(Sr_2CaCu_2O_6)$ in the *polysomatic* series with the end-members $(Sr,Ca)_2(Sr,Ca)Cu_2O_6$ (*A*) and Bi_2O_3 (*B*) or in another polysomatic series with the end members $CaCuO_2$ (infinite layer structure) and $Sr_{1+x}Bi_{1-x}O_3$ (perovskite with monoclinic distortion).

Layered cuprates with Cu_2O_3-planes (ladder-type structures) : The $[M_2Cu_2O_3]_m[CuO_2]_n$-type phase (M=Sr, Ca, Bi) of incommensurate structure can be considered in the polysomatic approach as the polysome $[MCu_2O_3]_m[M_{m/n}CuO_2]_n$ (AB) [4].

Polysomatic series in the structures of doped Ca, Sr-cuprates : The general scheme of polysomatic series in the structures of earth alkaline cuprates is proposed. The scheme allows one to predict the formation of new structural types in the group of doped Ca, Sr-cuprates.

P05.09.009 CRYSTAL STRUCTURE OF THE SOLID SOLUTION $Li_xMg_{(17-x)}Al_{12}$ (x = 3.64). G.S. Dmytriv, V.V. Pavlyuk and O.I.Bodak, Inorganic Chemistry Department, Ivan Franko Lviv State University, Kyryla I Mefodia str. 6, 290005 Lviv, Ukraine, and R.Cerny and K.Yvon, Laboratoire de Cristallographie, Universite de Geneve, 24, quai Ernest-Ansermet, CH-1211 Geneva 4, Switzerland.

Existence of a solid solution with wide homogeneity range based on the $Mg_{17}Al_{12}$ binary compound (superstructure to the α-Mn type) was confirmed [1] in the Li-Mg-Al system at 470 K. We have investigated this solid solution using X-ray diffraction methods (single crystal and powder). The single crystal was obtained from a three-phases alloy with the nominal composition $LiMgAl_2$. Structure was refined in the $I\bar{4}3m$ space group, a=1.0266(5) nm, Stoe Stadi4 diffractometer, MoK_α radiation with graphite monochromator, ω/2θ scan mode, 189 unique reflections, Xtal3.2 program, R=0.054, wR=0.026, GoF=1.344. Atomic positional, equivalent isotropic displacement and site occupation parameters are given below:

Atom	Site	x/a	y/b	z/c	U	PP
Al(1)	24(*g*)	0.0926(3)		0.2799(3)	0.0200(8)	
Mg(1)	2(*a*)	0		0	0.023(7)	0.80(7)
Li(1)	2(*a*)	0		0	0.023(7)	0.20(7)
Mg(2)	8(*c*)	0.3213(4)		x	0.030(4)	0.74(4)
Li(2)	8(*c*)	0.3213(4)		x	0.030(4)	0.26(4)
Mg(3)	24(*g*)	0.3581(4)		0.0382(4)	0.020(1)	0.80(2)
Li(3)	24(*g*)	0.3581(4)		0.0382(4)	0.020(1)	0.20(2)

The same results were obtained also by the powder Rietveld refinement. The Li atoms substitute only the Mg atoms because of the similar atomic radii.

P05.09.010 $DyCu_{5-x}$ - A NEW SUPERSTRUCTURE DERIVED FROM CUBIC $AuBe_5$-TYPE. L. Guénée, R. Cerny and K. Yvon, Laboratoire de Cristallographie, University of Geneva, 24, quai Ernest-Ansermet, CH-1211 Geneva 4, Switzerland.

A compound $DyCu_{5-x}$ crystallises with monoclinic symmetry. Its structure is derived from the cubic $AuBe_5$-type structure. The analysis of precession photographs lead us to determine the 3x3x2.5 supercell having the cell parameters a^s = 21.48 Å, b^s = 21.38 Å, c^s = 17.90 Å, β = 93.5°.

This structure is compared to that of $YbCu_{4.5}$, which crystallises also in structure derived from $AuBe_5$-type however in a supercell of the multiplicity 7x7x6.5 [1]. In this compound, the ordering of planar defects parallel to {hhh} is responsible for the superstructure.

Based on the investigations of $YbCu_{4.5}$, a model to explain the supercell multiplicity of $DyCu_{5-x}$ is proposed, which leads to a prediction of new series of compounds in the RE-Cu systems.

P05.09.011 VARIABLE TEMPERATURE X-RAY DIFFRACTION STUDY OF $BiMg_2VO_6$. I. Radosavljevic, A.W. Sleight, Department of Chemistry, Oregon State University, Corvallis, OR. 97331, U.S.A.

Bismuth magnesium vanadate, $BiMg_2VO_6$, belongs to the BiM_2AO_6 (M=divalent cation, A=pentavalent cation) family of compounds. The structures of these phases can be described as consisting of three common structural elements: one-dimensional BiO_2 chains, AO_4 tetrahedra and interspersed M cations [1,2].

The room temperature structure of $BiMg_2VO_6$, solved from single crystal X-ray diffraction data, was reported in 1992 [3]. The compound was reported as centred orthorhombic, space group Amma. Despite a very good agreement factor obtained for the refinement, the thermal ellipsoid on one of the oxygen atoms was of problematic size and shape.

A variable temperature X-ray diffraction experiment was carried out in order to gain an understanding of this situation. Six data collections were performed in the range from 100 K to 350 K. Refinements of the data sets indicated that the low temperature structure is in fact primitive orthorhombic and that the compound undergoes a centring phase transition above room temperature. The transition is a low energy one and it involves mainly the rotation of the VO4 tetrahedra.

P05.09.012 THE ORDERED PHASES OF THE W_2C CARBIDE AND PHASE EQUILIBRIA IN THE W-C SYSTEM. T.Ya. Velikanova and V.Z.Kubliy, I.N.Frantsevich Institute for Problems of Materials Science, National Academy of Science of Ukraine, Kiev, Ukraine.

In the handbooks [1-3] published recently there are contradictions. They deal with the quantity, sequence of the change and type of the ordering of the W_2C modifications.

The W-C alloys containing W_2C carbide were melted in an arc melting furnace and then annealed at subsolidus temperature about 1.5 hour. After that the alloys were subjected either annealing at 1450-2650°C and following quenching or long-time (hundreds of hours) annealing lower 1200°C.

The single-crystal X-ray method was applied for crystal grains extracted from the alloys. The method is more informative in comparison with powder diffraction (X-ray and neutron) even at investigation of ordering in carbides of such "heavy" metals as Mo and W [4,5].

In first we obtained the sufficiently total sets of extra reflections appearing due to ordering carbon atoms. The W_2C carbide was shown to exist in two hexagonal modifications, the ordering phase of ε-Fe_2N type and disordering L'3 one. At 1250°C and lower the carbide undergoes to decomposition (W_2C ∀ W +

WC) and to form the metastable ordering orthorhombic modification of ζ-Fe_2N type.

On the bases of obtained results we represent the reviewed the W-C phase diagram.

P05.09.013 NEW PHASE $Cr_4(P_2S_6)_3$: ROOM TEMPERATURE SYNTHESIS AND CHARACTER-IZATION*. Z.L. Huang, J.T. Zhao, J.X. Mi, S.Y. Mao, L.S. Zheng, Department of Chemistry, Xiamen University, 361005-Xiamen, People Republic of China and S.Vilminot, Groupe des Materiaux Inorganiques de l'IPCMS, EHICS, 1, rue Blaise Pascal, B.P.296, 67008 Strasbourg Cedex, France.

In the last two decades, considerable interest has been focused on the first row transition metal hexathiodiphosphate $M_2P_2S_6$[1] (M=Mn, Fe, Co, Ni, Zn) . It is reasonable to expect metal deficient compounds of the $M_2P_2S_6$ type with a M^{3+} cation, many efforts were made to obtain $Cr_{4/3}[\ ]_{2/3}P_2S_6$ phase by the traditional high temperature method but failed. Here we report the synthesis and characterization of this new phase by solid state reaction between $Na_4P_2S_6{\cdot}6H_2O$ and $CrCl_3{\cdot}6H_2O$ at room temperature rather than by the ceramic method. The process of reaction by grinding and the heat treatment of reaction products were monitored by XRD, implying the following reaction route.

$$4CrCl_3{\cdot}6H_2O + 3Na_4P_2S_6{\cdot}6H_2O \rightarrow Cr_4(P_2S_6)_3 + 12NaCl + 44H_2O$$

The final product was characterized by means of XRD, Raman spectroscopy and magnetic measurements. XRD shows that the compound, isostructural with $Ga_4(P_2S_6)_3$[2], crystallizes in the monoclinic system with a=0.8692(5)nm, b=0.7562(6)nm, c=0.8344(6)nm, β=91.97(7)°. The most intense peak at 381cm^{-1} of the Raman spectrum bearing the characteristics for the $P_2S_6^{4-}$ anion group is attributed to the mixed symmetric P-P and P-S stretching modes. Magnetic susceptibility measurements showed the Curie-Weiss type with number of Bohr magnetons 3.62μ_B/Cr, revealing the existence of a d^3 Cr^{3+} cation. These results correspond to the charge balance $Cr^{3+}{}_4(P^{4+}{}_2S^{2-}{}_6)_3$.

P05.09.014 $RECu_{1+x}Sb_2$ (RE = La, Ce, Pr, Nd, Sm, Gd, Tb, Dy, Ho and Y) WITH DEFECT $CaBe_2Ge_2$ - TYPE*. S.K.Zhou, J.T.Zhao, M.H.Song, J.X.Mi, Z.L.Huang, S.Y.Mao, College of Chemistry and Chemical Engineering, Xiamen University, Xiamen 361005, P.R.China

Non-stoichiometry seems to be a characteristic feature for many ternary AT_2X_2 (A = rare earth metals and actinoides, T = late transition metals and X = p-block elements) compounds which adopt the primitive tetragonal $CaBe_2Ge_2$ structure [1]. In the RE-Cu-Sb systems $CeCu_2Sb_2$ was the only phase reported [2] with the $CaBe_2Ge_2$ type but no detailed information on the Cu deficiency was given. The ten title compounds are synthesized by arcmelting methods and their crystal structures refined using X-ray powder Rietveld method and DBWS-9006PC package [3]. For the light rare earth (RE = La, Ce, Pr, Nd, Sm) compounds, one of the copper sites is partially occupied (reaches the maximum for $LaCu_{1.39}Sb_2$), while the occupancies of the same site are almost negligible for the compounds with rare earth metals heavier than Gd including Y metal leading to 1:1:2 stoichiometry. The unit cell parameters show lanthanide contraction. The three dimensional structure is characterized by intergrowth of two distinct layers along c-axis. One layer is quite rigid and formed by connected covalent bonded Cu-Sb tetrahedra. While another layer is quite flexible which consist of bonded Sb square net and the disordered Cu atoms. The ability of accommodating disordered Cu atoms in the voids decrease with lanthanide contraction.

The idea of "Metallic Zintl Phase" has provided us with new viewpoints of deeper and wider understandings of intermetallic compounds with transitional bonding features in a large category of which the structures follow the Zintl Rule down playing their weak metallic conductivity properties [1]. The title compounds were synthesized by arcmelting method and their crystal structures were characterized by powder X-ray Rietveld methods and DBWS-9006PC package[2]. Crystallographic data: cubic system, $Y_3Au_3Sb_4$-typecI40, space group I-43d, Z=4. Unit cell parameters$Nd_3Cu_3Sb_4$: a = 9.6749(1)Å, V = 905.61(3)$Å^3$;

P08.09.004 STRUCTURAL RELATIONSHIP BET-WEEN CATHO-DOLUMINESCENCE AND DISLOCATION ROZETTES BY MICROINDENTATION. Daria Z. Grabco, Institute of Applied Physics, Academy of Sciences, Academy str.5. MD-2028, Chisinau, Moldova

Microstructure and specific deformation of KCl, LiF and MgO ionic crystals are investigated by (001) plane microindentation in large tempera- ture interval ($T_{def.}$=77-800K).

On the MgO single crystals it is shown that the good correlation be- tween the dislocation arrangement in crystals volume near indentations and cathodoluminescence image is observed in temperature interval T_{def}=0.03- 0.15$T_{melt.}$

Relationship of principal deformation regularities by microindentation with thermal properties of investigated crystals, in particular, with De- bye temperature (θ_D) is established; it is revealed that temperature about θ_D corresponds to border that separates the temperature region between frail and plastic deformation mechanisms by formation of indentations.

It is shown that cathodoluminescence rosettes equal in size to dislocation ones appear aroud the indentations by deformation temperature T_{def}<0.5 θ_D. With temperature growth the dimension of cathodoluminescence rosettes decreases unlike the dislocation structures, and by $T_{def.} \approx 1.0\ \theta_D$ the luminescence occupies the area hardly bigger then indentation size. The rest of dislocation rosette is dark.

Obtained results indicate that various temperature stages of crystals deformation exist by microindentation in large temperature interval.

P08.09.005 A DISORDERED PHASE OF MANGANOUS FLUOSILICATE HEXAHYDRATE AT HIGH TEMPERATURE. Golam Mostafa and Siddhartha Ray, Department of Solid State Physics, Indian Association for the Cultivation of Science, Calcutta 700032, India.

Room temperature structure of $MnSiF_6.6H_2O$ crystals consists of domains of periodic orientational antiphase. An individual domain has symmetry $P\bar{3}$ but existence of mirror-related domains in equal quantity augments the symmetry to $P\bar{3}m$. Below -50^{0}C the crystal has an ordered monoclinic structure. Antiphase being generally an intermediate state between an ordered and a disordered phase, a disordered phase of the crystal at high temperature was expected.

A DSC curve showed a peak at 57^{0}C. Weissenberg photographs of the crystal maintained at 66^{0}C showed that the spots with $-h+k+l=3n\pm1$ were absent. The symmetry was found to have become $R\bar{3}m$. This indicates that in the high temperature phase, while Mn and Si are situated on the 3-fold axes, O and F are randomly distributed in equal numbers among mirror-related general positions, giving rise to disorder.

It was also observed that in first layer Weissenberg photographs about *c*-axis, taken at intervals of 10^{0}C from room temperature to the transition temperature, intensity of the spots with $-h+k+l=3n\pm1$ diminished gradually. This indicates that the process of randomisation of O and F positions starts with raising of temperature and at the transition temperature, the process is accelerated and takes place *en masse.*

P08.09.006 DESTRUCTION MODELS OF SOME LAYER MINERALS. Arkhipenko D.K., Moroz T.N., Grigorieva T.N. United Institute of Geology, Geophysics and Mineraloqy, Siberian Branch RAS, 630090 Novosibirsk, Russia.

Infrared spectroscopy and X-ray powder diffraction methods were used to study structural transformation and destruction of some layer minerals, namely, natural hydrotalcite, hydrotalcite-serpentine, chlorite, flogopite after temperature, pressure, T+P treatment. X-ray diffraction patterns show the dynamic of change of CO32+-H2O interlayer space of hydrotalcite-serpentine up to 260oC after T-treatment and up to 300oC after p+T treatment. Reflections d 003, d 006 decrease from 7.71A, 3.84 A to 6.60, 3.64 A and increase after pressure influence in autoclave (T=300oC, 24h) to 8.6, 4.31A, respectively. We observed 6.6 and 5.52A reflections for natural hydrotalcite samples after heating at 250 o C, 5h, the latter being absent in hydrotalcite-serpentine sample. 300-600oC temperature interval both hydrotalcite and hydrotalcite-serpentine are X-ray amorphous. In this temperature interval we can determine the transformation of the structure by means of IR spectroscopy. The pattern of the two different dehydroxilated phases: forsterite (olivine) and enstatite, are observed in 1000oC thermal decomposition of hydrotalcite-serpentine, chlorite, (flogopite) in different composition. The structure and composition of resulting product are shown to depend on regime of heating (dynamical, isoteral, heating in stone skin, in atmosphere or in aqueous solution), joint T+P influence or separately.

As consequence, for minerals with important industrial properties it is possible to choose such regime of T,P influence which may give the necessary products, to offer an explanation for anomalous combination of minerals in natural conditions and to model different geological process.

This work was supported in part by RFBR Foundation No 98-05-65204a.

P08.09.007 PHASE RELATIONS OF ZRO2 UNDER HIGH PRESSURE AND TEMPERATURE. O. Ohtaka, H. Fukui, T. Fujisawa [1], K. Funakoshi [2], W. Utsumi [3], T. Irifune [4], [1] Earth and Space Science, Osaka University, Toyonaka, Osaka 560-0043, Japan, [2] JASRI, Spring-8, Sayo-gun, Hyogo 679-5198, Japan, [3] JAERI, Spring-8, Sayo-gun, Hyogo 679-5198, Japan, [4] Earth Sciences, Ehime University, Matsuyama, 790-8577, Japan

In order to reveal the phase relation and the crystal structures of high pressure and temperature ZrO_2 phases, we have attempted a series of in situ observations by means of the double stage multi-anvil type high pressure apparatus, SPEED 1500 system, installed at SPring-8. Using this system, it has become possible to perform x-ray in situ experiments in energy dispersive mode up to 25GPa and 2000°;.

We found that cotunnite-type ZrO_2, orthoII, is stable up to 1800°; at pressures ranging from 14 to 21 GPa and determined the phase boundary between orthoII and fluorite-type ZrO_2.

The present results are remarkably different from those of previous works mainly done by synthesis experiments. Obtained orthoII-orthoI phase boundary is located at a lower pressure region and its slope is much more steep comparing with previous results. OrthoII is stable at as high as 1800°;. By quench experiments, a boundary between orthoII and its high temperature phase (hexagonal phase?) was determined; orthoII is quenchable below 1100°; while samples heated above 1100°; reverted to monoclinic on releasing pressure, which suggests the existence of another unquenchable phase. Combining DAC and laser heating, thermally quenched ZrO_2 under pressure was found to have a hexagonal symmetry. The hexagonal phase, however, has not been observed in the present experiments. The hexagonal phase may be an artifact produced by uniaxial compression in DAC and laser heating accompanying large thermal gradient. In our present study, when orthoII formed at 1400°; at 20 GPa is quenched under pressure and decompressed at room temperature, it shows a reverse transition to monoclinic phase. This mystery about the quenchability of orthoII is still left to be solved.

P08.09.008 $Ca_3TiSi_2(Al_2Si_{0.5}Ti_{0.5})O_{14}$, A NEW HIGH-PRESSURE PHASE IN A PETROLOGIC RELEVANT SYSTEM. P. Scheuermann, A. Kutoglu, M. Schosnig and E. Hoffer, Department of Earth Sciences, Philipps University Marburg, D-35032 Marburg, Germany.

In the course of systematic studies to investigate the dependencies of element partitioning on pressure, temperature and compositional variations in the system $CaO-Al_2O_3-TiO_2-SiO_2$ (CATS) a new alumo-titanium-silicate phase with the idealized formula $Ca_3TiSi_2(Al_2Si_{0.5}Ti_{0.5})O_{14}$ was identified.

The new phase is present in all experimental run products at pressures above 1.2 GPa and temperatures of 1375°C and is part of the equilibrium paragenesis with anorthite, titanite, perovskite, and liquid in the pseudoternary section anorthite-titanite-perovskite of the CATS system. The experiments have been performed from atmospheric conditions up to 1.5 GPa at 1300° - 1500°C using double ellipsoid mirror furnace and piston cylinder apparatus. All phases have been checked for homogeneity with electron microprobe and by SEM element mappings.

The structure of $Ca_3TiSi_2(Al_2Si_{0.5}Ti_{0.5})O_{14}$ has been determined with X-ray diffraction data on a single crystal (dimension 0.8 x 0.3 x 0.2 mm) with a conventional four circle diffractometer whereby the space group P321 with a=7.943(1)Å and c=4.930(1)Å was found. The diffraction data indicate that the new compound consists of two different layers parallel (001), in which sheets of corner linked pure SiO_4 and statistically distributed (Al, Si, Ti)O_4 tetrahedra centered at z=1/2 alternate

with those sheets occupied by six fold coordinated Ti^{4+} and eight fold coordinated Ca^{2+} at z=0.

The identified type of structure with the general formula $A_x^{[8]}B_y^{[6]}T_z^{[4]}O_{14}$ is also known for some synthetic germanates [1] and another high-pressure silicate $Na_{1.8}Ca_{1.1}Si_6O_{14}$ [2].

P08.09.009 STRUCTURAL CHANGES OF $ZnFe_2O_4$ AT HIGH PRESSURE. D. Levy and M. Hanfland, ESRF, BP 220 F-38043 Grenoble Cedex, France and A. Pavese, Dip. di Scienze della Terra, Università di Milano, V. Botticelli 23, 20133 Milano, Italy

Franklinite ($ZnFe_2O_4$) is an oxide-mineral with spinel-like structure (Fd3m, Z=8). The studied sample was synthetic and was structurally and chemically characterised by X-ray powder diffraction and X-ray fluorescence. The chemical formula was found to be $Zn_{0.97}Fe_{2.02}O_4$ (0.1 vacancies p.f.u.) and spinel structure can be described as 'normal' (4-fold co-ordinated Zn^{2+} and 6-fold co-ordinated Fe^{3+}). The high-pressure experiment was performed with a Diamond Anvil Cell (DAC) at ID9 (ESRF, Grenoble, France). Powder diffraction patterns were collected with the angle dispersion technique, by means of an image plate, in the pressure range 1.8-36.2 GPa and sequentially analysed with the Rietveld method. The only structural degree of freedom in spinel-like structure is the co-ordinate of oxygen that shifts along [111]: this co-ordinate was refined to study the distortion of cation sites. The cell volume exhibits a smooth trend up to 25 GPa, and it can be fitted by the Birch-Murnaghan equation of state [1]. The following elastic properties were obtained: B_0=166.4 GPa, B'_0=9.3. Above 24.4 GPa, a new phase along with spinel was observed and was attributed to a $CaTi_2O_4$-like structure ($Bb2_1m$, Z=4). In this phase, Zn^{2+} changes co-ordination number from 4 to 8 (tetrahedron→two-cap trigonal prism), while Fe^{3+} is still co-ordinated 6-fold (octahedron). The cell-edge and the structure of the high-pressure phase were refined to analyse its compression behaviour, but not enough points have been collected to extrapolate the equation of state.

P08.09.010 HIGH-PRESSURE PHASE TRANSITION IN SPODUMENE $LiAlSi_2O_6$. Thilo Arlt and Ross Angel, Bayerisches Geoinstitut, University of Bayreuth, D-95440 Bayreuth

The single-chain silicates of the pyroxene group, generally $M2M1Si_2O_6$ are known to exhibit a complicated polymorphism with pressure and temperature. Clinopyroxenes with low Ca- or Na-contents, e.g. enstatite-ferrosilite, pigeonite and kanoite, undergo displacive phase transitions at high-pressure in which the symmetry increases from space group $P2_1/c$ to HP $C2/c$. In enstatite that phase transition causes a weak seismic dicontinuity in the Earths upper mantle. In this study we found a symmetry change from $C2/c$ to $P2_1/c$ which is opposite to the transformation reported in other pyroxenes with increasing pressure.

The high-pressure behavior of natural spodumene $LiAlSi_2O_6$, space group $C2/c$ was studied by single-crystal X-ray diffraction in a diamond-anvil cell. Nonlinearities of cell parameters and birefringence showed a displacive phase transition at about 3.2 GPa. The transformation is rapid, reversible, non-quenchable and first order in character. The cell dimension b increases while a, c and the angle β decrease strongly resulting in a total volume decrease of about 1.3 % at the transition. The h + k = odd reflections, characteristic of a primitive lattice, appear suddenly at the phase transition. The space group $P2_1/c$ of high-pressure spodumene was confirmed by structure refinement from single-crystal X-ray intensity data collected in a diamond-anvil cell at 3.3 GPa. At ambient conditions both chains are S-rotated (O3-O3´-O3´´= 170.5°) but they become distinct in the high pressure form which decreases the symmetry to $P2_1/c$. While the A-chain remains S-rotated with an O3-O3´-O3´´ angle of 157.0(4)°, the B-chain rotates about 37° during the phase transition to an O-rotated chain angle of 152.4(5)°.

High-pressure phase transitions from $C2/c$ to $P2_1/c$ were also observed in the clinopyroxenes $LiScSi_2O_6$ at about 0.6 GPa and $ZnSiO_3$ at 1.9 GPa. To explain that observation, the C-centered forms at ambient conditions are considered to be isotypic to the high-temperature (HT) $C2/c$ polymorphs of, e.g. $MgSiO_3$ and $FeSiO_3$. Consequently, the high-pressure polymorphs of Li-pyroxenes are equivalents to the low-$P2_1/c$ clinopyroxenes. In LiSc-Cpx the nonlinearities in cell parameters are significant, but much weaker than those found in spodumene and those reported in temperature dependent $P2_1/c$-HT $C2/c$ phase transitions (best studied in pigeonite). The continous and linear increase of h+k = odd reflections indicate a second order transformation mechanism for $LiScSi_2O_6$. In $ZnSiO_3$ the intermediar $P2_1/c$ phase further transforms to the HP-$C2/c$ form at about 5.1 GPa which confirms that HT $C2/c$ and HP $C2/c$ clinopyroxenes have distinct stability fields in the P/T space.

P08.09.011 STRUCTURAL CHANGES IN TlF WITH TEMPERATURE AND PRESSURE. S. Hull, ISIS Facility, CLRC Rutherford Appleton Laboratory, Chilton, Didcot, Oxon OX11 0QX, UK and P. Berastegui, Inorganic Chemistry, Arrhenius Laboratory, Stockholm University, S-10691 Stockholm, Sweden.

The phase diagram of thallium(I) fluoride indicates the existence of three polymorphs [1]. The ambient (TlF-I) and high (TlF-II) temperature phases have been proposed to adopt distorted NaCl-type structures, probably due to the stereochemistry of the distorted Tl s^2 lone pair [1,2]. The existence of a third polymorph at high pressures (TlF-III) has been proposed from the calculation of very small volume changes by differential thermal analysis.

In this work, the structural behaviour of TlF with temperature and pressure has been studied using neutron powder diffraction measurements. In contrast to previous studies using single crystals (where the presence of weak reflections resulted in uncertainty in the space group determination), the ambient temperature structure has been unambiguously assigned to space group $Pbcm$ (No. 57) with a= 6.09556(8), b= 5.48860(7) and c= 5.18300(7) Å, Z=4. The structure can be fully described with Tl and F at 4d (x, y, ¼) sites, with the former near the ideal position but in a highly irregular fluoride ion co-ordination with four short Tl-F bond lengths (2.43-2.71 Å) and two longer at 3.12 and 3.70 Å. The high temperature structure was investigated at 90°C and refined in space group $P4/nmm$ (No. 129) with a= 3.78283(2) and c= 6.12312(5) Å, Z=2. The two ions can be located at 2c (¼, ¼, z) sites, with Tl near the ideal position at z= 0.7461(2) and F at z= 0.1426(2). This results in a more regular octahedron with Tl-F bond lengths of 2.43, 2.76 (×4) and 3.69 Å. TlF was also studied at pressures up to 4 GPa but no structural transition was observed. There are no significant changes in the atomic positions, though the a-axis is found to be somewhat more compressible than the other two axes.

P08.09.012 HIGH TEMPERATURE SUPERIONIC PHASES IN THE $(PBF_2)_{1-X}$-$(MF)_X$, SYSTEMS WITH M= K, RB AND CS. P. Berastegui, Inorganic Chemistry, Arrhenius Laboratory, Stockholm University, S-10691 Stockholm, Sweden and S. Hull, ISIS Facility, CLRC Rutherford Appleton Laboratory, Chilton, Didcot, Oxon OX11 0QX, UK.

The crystal structure and ionic conductivity of polycrystalline samples of PbF_2 doped with KF, RbF and CsF have been investigated at temperatures up to ~700K using neutron diffraction and complex impedance measurements. The maximum solubility of KF in β-PbF_2 was found to be about 1 %, while the creation of charge compensating anion vacancies induced an increase in the ionic conductivity at ambient temperature by a factor 5.6×10^3. At higher KF contents of $0.333 \leq x \leq 0.68$, a high temperature superionic phase with a body centred cubic cation sublattice was observed above a transition temperature of T_c ~ 520-590 K, with a related abrupt increase in the ionic conductivity. Within this high temperature modification, the anions are predominantly disordered over the tetrahedral interstices, and its structure can thus be described as an *anti* α-AgI type. In the case of $(PbF_2)_{1-x}$-$(RbF)_x$, an increased tendency towards ordering of the two cation species over the 0,0,0 and ½,½,½ sites was observed as the dopant content increased within the stability range $0.333 \leq x \leq 0.5$. This is accompanied by a change in the preferred anion location towards the octahedral positions as the mean structure tends towards a partially ordered perovskite-type arrangement. A fully ordered perovskite-type structure was observed in the $(PbF_2)_{1-x}$-$(CsF)_x$ system where only a single line phase at x = 0.5 can be observed. This phase shows no evidence of superionic behaviour at elevated temperatures.

P08.09.013 HIGH TEMPERATURE STRUCTURE TRANSITIONS OF $SrHFO_3$. S.L. Cuffini [1], J.A. Guevara, Y.P. Mascarenhas [2], A.N. Fitch[3]. [1] INFIQC, Fac. Ciencias Quimicas. U.N.C. Agencia 4, CP. 61 - Córdoba. Argentina. [2] IFSC-USP, C.P. 369-15690-970. Sao Carlos. Brazil. [3] ESRF, BP 220, F-38043 Grenoble Cedex, France.

Strontium hafniate (SH) is a refractory compound melting at 2730 C, which belongs to the perovskite family. Although this compound has been known for well over 50 years, the crystal structures at high temperature, where phase transitions have been reported, have not been examined thoroughly (1).The purpose of this work is to report the crystal structures of this compound not only at room temperature but also at high temperature in order to determine the nature of the structural phase transitions. The x-ray diffraction patterns collected at beam line BM16 at ESRF were refined using Rietveld Method and the temperature range studied was from room temperature up to 1000C. At room temperature, the structure showed a small deviation from the pattern of a cubic perovskite, however the small superlattice reflections could be refined in space group Pnma with lattice parameters, a=5.7889(2)A, b=8.1716(3)A and c=5.7772(2)A. At higher temperatures, SH showed a phase transition from Pnma to I4/mcm at around 500C and from I4/mcm to Pm-3m around 900C. This behaviour is comparable with other perovskite like SrRuO3 and SrZrO3 which exhibit similar transitions in this temperature range.

P08.09.015 HIGH PRESSURE STUDIES ON CHALGOGENIDE MISFIT LAYER STRUCTURES, AND THEIR COMPONENT STRUCTURES. Wulf Depmeier, Karsten Knorr and Lars Ehm, Institut für Geowissenschaften, Mineralogie / Kristallographie, Universität Kiel, Olshausenstr. 40, D 24098 Kiel, Germany

In the context of an interdisciplinary research project, comprising theoretical and experimental physicists, inorganic chemists and crystallographers, we have started an investigation into the high pressure behaviour of misfit compounds with the idealised formula $(MX)_{1+x}(TX_2)_m$ with M = Sn, Pb, Bi, Rare Earth; T = Ti, V, Cr, Nb, Ta and X = S, Se. The ultimate goal of the project is to gain a thorough understanding of the detailed geometrical and electronic structure of the compounds, and their associated properties.

The focus is on the interfaces between MX and TX_2 layers, and the van-der-Waals gaps between adjacent TX_2 layers. In order to facilitate the understanding of the complex and usually aperiodic misfit compounds [1], we decided to start high pressure work on the much simpler component structures, such as PbS, 1T-TiS_2, and 2H-NbS_2. Despite their simplicity, very little is known about the high pressure behaviour of these compounds. Experiments use x-ray powder diffraction in diamond anvil cells up to 100 kbars. The high pressure studies on misfit compounds and their component structures are interesting, because the topology of the structures, the electronic configuration of the constituents, and the band structures of the crystals promise to present a rich phenomenology [2]. The experiments are accompanied by theoretical studies on the ab initio level, performed in parallel in our group.

P08.09.016 COMPLEX OXIDES WITH OCTAHEDRAL FRAMEWORKS: LEWISITE AND LOPARITE. N. V. Zubkova, D. Yu. Pushcharovsky, Geology Department, Moscow State University, 119899 Moscow, Russia, Arakcheeva A. V., Institute of Metallurgy RAN, Leninsky av., 49, 117334 Moscow, Russia, D. Atencio, University of Sao Paolo, Sao Paolo, Brasil

Pyrochlore - like structure of lewisite (general formula - $A_{2-m}B_2[O_6(OH)]$ from Tripui, Ouro Preto, Minas Gerais, Brazil was refined up to R_{hkl} = 0.022 in space group *Fd3m*, a = 10.311(6)Å, V = 1096.23Å^3. The averaged results of the EDS chemical analyses corresponded to the chemical formula: $(Ca_{0.91},Na_{0.12},Fe_{0.22},Al_{0.13},Sb^{3+}_{0.32})(Sb^{5+}_{1.27},Ti_{0.72})O_6(OH)$.

Similarly to pyrochlore [1], the structure of lewisite is based on a defect simple cubic packing of (OH) - groups and O atoms, with A - and B - atoms occupying 1/2 of cubic voids. Large A - cations have cubic coordination and B - atoms - 6 coordination due to the vacancies.

Crystal structure of loparite, $(Ti,Nb)(Na,Ce,Ca,Sr)O_3$ from Lovozero alkaline massive, was refined up to R_{hkl} = 0.041 in space group *Pn3m* with double perovskite parameters of the cubic unit cell a = 7.767(1)A [2]. The lattice dimensions of loparite are doubled because of the ordering of A - and B - cations. Thus loparite can be characterized by general formula $A'A''_3B'_2B''_2O_{12}$.

Both structures comprise the octahedral frameworks. In loparite the voids are filled by ordered Ca,REE and Na,REE cations. In lewisite the voids are filled by (OH) - group surrounded by 4 (Ca,Sb) - cations.

P09.09.001 CHEMICAL PROPERTIES OF TRANSITION METAL CATIONS IN ION EXCHANGED ZEOLITES. AN AB INITIO STUDY. Judit E. Šponer, J. Heyrovský Institute of Physical Chemistry, Academy of Sciences of the Czech Republic, Dolejškova 3, Prague 8, Czech Republic

This study is intended to provide a generalised view on the basic chemical properties of Fe^{2+}/Fe^{3+}, Cu^{+}/Cu^{2+}, Co^{2+}, and Ni^{2+} containing zeolites. Siting of transition metal cations in a number of zeolites of various structural types has already been investigated employing both spectroscopic (UV-VIS, IR, EPR) and diffraction (EXAFS) techniques.

Simple models have been optimised at DFT/Becke3LYP level of theory. Different aluminium distribution in high and low silica zeolites has also been taken into consideration. Charge density distributions have been analysed to interpret the influence of the zeolite matrix on the redox properties of the various transition metal cations.

It has been found that metal cations possessing two stable oxidation states (such as Fe^{2+}/Fe^{3+} and Cu^{+}/Cu^{2+}) tend to adopt the more stable one. Thus, in presence of one framework aluminium a considerable charge transfer has been found from Fe^{2+} to the aluminosilicate skeleton, the Fe^{3+} form with a d^5 electronic configuration being more stable than the less symmetrical Fe^{2+} form (d^6). On the contrary, copper is trying to adopt the more stable d^{10} electronic configuration by a charge transfer from the skeleton to Cu^{2+} resulting in formation of Cu^{+} ions (d^{10} closed shell electronic configuration). In presence of water the charge transfer between the aluminosilicate skeleton and the metal cation is weaker because of the negative charge donated by the water ligand. Weak Lewis base molecules, such as CO have a much weaker impact on the charge distribution between the metal and the zeolite.

P09.09.002 IDENTIFICATION AND ENRICHMENT OF INDONESIAN ZEOLITE USING CATION FLOATATION METHOD. Muhammad Hikam, Department of Physics, Faculty of Mathematics and Sciences, University of Indonesia, Depok 16424 Indonesia, Endang Asijati and Dian Ratnasari, Department of Chemistry, University of Indonesia, Depok 16424 Indonesia.

Most of natural zeolite in Indonesia contains mordenite type A, $[Na_2CaK_2]$ $Al_2Si_{10}O_{24}.7H_2O$. This material has many valuable applications in agriculture, environment and energy; it could be used as adsorbent and ion exchange, however the purity of this natural product is too low for direct use. We have employed cation floatation method to enrich the A-modernite fraction by observing the change of the mixture density, pH, type and concentration of collector and concentration of HF as function of the floated quantity of this A-mordernite.

X-ray diffraction analysis using Shimadzu XD-D1 was conducted to examine the specimens for several variations and settings. The d-spacing identifications were done by comparing the experimental data with the ICDD database and then quantitative analyses were performed. Before the treatment, the existence of A-mordenite in this natural product was confirmed, it has space group Fd3m with lattice parameters a = (24.46 ± 0.96) Å. The average weight concentration before the treatment was 41,02%. The remaining mineral identified as epistilbite $Ca_3Si_9Al_3O_{24}.8H_2O$, clinoptilolite $[KNa_2K_2]$ $Al_2Si_{10}O_{24}7H_2O$ and B-mordernite $[CaNa_2K_2]Al_2Si_{10}O_{24}.7H_2O$.

After the treatment, higher concentration of A-mordenite was obtained by setting higher collector concentration, lower HF activator and pH value to the value 5.0. The highest concentration of A-mordenite achieved by the setting was 66.45%. The crystallographic structure remained the same since there was neither violence chemical reactions nor heating in all the processes.

P09.09.003 MINERALS AND SYNTHETIC COMPOUNDS WITH OPEN FRAMEWORK STRUCTURES: NEW DATA. O.V.Yakubovich, Moscow Lomonosov State University, Department of Geology, Vorob'evy Gory, 119899 Moscow, Russia and W.Massa, Philipps-University, Department of Chemistry, D-35032 Marburg, Germany.

The results of X-ray crystal structure investigations of two natural molecular sieves - a pure alkali variety of merlinoite and a K-variety of chabazite, the new zeolite-like mineral bakhchisaraitsevite and a synthetic microporous Mn-phosphate, are presented.

cryst.	merlinoite	chabazite	bakhchisarai-tsevite	Mn-phosphate
form-ula	$Na_5K_7(H_2O)_{24}$ $[Al_{12}Si_{20}O_{64}]$	$K_6Na_4Ca(H_2O)_{27}$ $[Al_{12}Si_{24}O_{72}]$	$Na_2\{(Mg_{4.5}Fe_{0.4}$ $Mn_{0.1})[PO_4]_4$ $(H_2O)_6\}H_2O$	$Mn_3[PO_4]_2$ $0.5H_2O$
unit cell	a 13.840(3)	13.840(7)	8.3086(8)	9.310(7)
	b 14.104(2)		12.906(1)	17.414(9)
	c 10.040(3)	15.100(9)	17.486(1)	8.161(3)
, (°)	β		102.01(1)	92.58(5)
sp.gr.	*I m m m*	*R* $\bar{3}$ *m*	*P* $2_1/c$	*C c*
Z	1	1	4	2
T	120 K	300 K	193 K	300 K
R	0.043	0.054	0.033	0.033

The structure refinements of merlinoite, chabazite and $Mn_3[PO_4]_20.5H_2O$ had to be done with the supposition of twinning of the crystals. The disorder of the tetrahedral framework has been found in chabazite. The interdependence between the degree of orthorhombic distortion in the merlinoite structure and the way of interstitial component distribution is discussed. The positions of all hydrogen atoms have been found and refined in the cases of the new mineral bakhchisaraitsevite and synthetic Mn-phosphate hemihydrate.

P09.09.004 A STUDY OF THE NEW ION EXCHANGED DERIVATIVES OF HIGHLY CRYSTALLINE LOW-SILICA MAP. Jose Geraldo Nery [1], Yvonne P. Mascarenhas [1], Anthony K. Cheetham [2], [1] Instituto de Fisica de Sao Carlos-USP, Cx. Postal 369,CEP 13560-970, Sao Carlos, SP, Brazil, [2] Materials Research Laboratory, University of California, Santa Barbara, CA 93106.

This is an extensive study of the Cd-MAP, Mn-MAP, Ba-MAP, Sr-MAP and Pb-MAP, the new ion exchanged derivatives of highly crystalline low-silica NaP with an Si/Al ratio of 1.0. All the structures were refined from conventional X-Ray data in the monoclinic crystal system and all the structures have the GIS framework topology. The extra-framework sites for Cd, Mn, Ba, Sr, Pb and water molecules were located. The incorporation of Cd, Mn, Ba, Sr and Pb cations produces distortions in the GIS framework due to its high flexibility. Besides the distortions induced by the cations incorporation, the Si NMR data and the Si-O and Al-O bonds show that all the structure present a strict ordering scheme of Si and Al. The number water molecules per unit cell differs between the title compounds, as does their dehydration behaviour. Dehydration of Cd-MAP and Mn-MAP induces the formation of new phases, however under rehydration conditions these new phases are restored to the original ones. On the other hand, dehydration of Sr-MAP and Pb-MAP induces the formation of new phases which are irreversible under rehydration conditions. Dehydration of Ba-MAP at 140-180C induces the formation of a new phase which is restored to the original one under the rehydration conditions. However, above this temperature range the new phases formed are irreversible.

P09.09.005 A $^{69/71}$GA AND ^{29}SI MAS NMR STUDY OF ZEOLITE-ANALOGUE GALLOALUMOSILICATES WITH CANCRINITE STRUCTURE. F. Stief, M. Fechtelkord, J.-Chr. Buhl, Institut für Mineralogie der Universität Hannover, Welfengarten 1, D-30167 Hannover, Germany.

Isomorphous substitution of aluminium by gallium on framework positions of zeolites has a large influence on the

catalytic and sorption properties. A well known application is the so-called Cyclar process, where short-chain paraffin molecules are converted to aromatics by using a gallium-loaded zeolite catalyst [1]. The most appropriate method to distinguish framework and extra-framework gallium is $^{69/71}$Ga NMR. Both nuclei have different quadrupolar properties which allow the determination of the individual coupling constant by observing both isotopes at the same static magnetic field. Most $^{69/71}$Ga MAS NMR spectra are accumulated with single pulse experiments but signal broadening and the occurrence of spinning sidebands require Hahn echo spectra with stepped offset (variable offset cumulative spectrum VOCS) [2]. Samples with different initial Al/Ga ratios have been synthesised at mild conditions to investigate the influence of framework gallium on the structure and properties on nitrate cancrinite. All specimens are highly crystalline with crystal sizes up to 20 μm. ^{29}Si MAS NMR spectra show different Q^4(nAl, (4-n)Ga) signals due to changes in the second coordination sphere of Si. The Al/Ga ratios deduced from these spectra are lower than the value of the initial materials of syntheses. The ^{29}Si MAS NMR resonance of the sample with Al/Ga = 0 is shifted to lower field compared with its alumosilicate analogue due to increased bond angles and the different electronegativity of gallium related to aluminium.

P09.09.006 STRUCTURE REFINEMENT OF AS-SYNTHESIZED VPI-5 AT 295 AND 90 K. C.L. Lengauer, T. Brehmer and E. Tillmanns, Institut für Mineralogie und Kristallographie, Universität Wien – Geozentrum, A-1090 Vienna, Austria, and J. de Onate, Laboratorium für Kristallographie, ETH, CH-8092 Zurich, Switzerland.

Common to some aluminophosphate molecular sieves is a channel type pore opening within the tetrahedrally coordinated framework, which is characterized by an alternate occupation of Al^{3+} and P^{5+} over the crystallographic T-sites. This atomic arrangement of the cations enables polar framework sym-metries, which are the basis for interesting physical properties in inorganic crystalline materials. In the case of VPI-5 with the VFI topology and a nominal composition of $Al_{18}P_{18}O_{72}\cdot 42H_2O$, the symmetry of the polar framework is further reduced from $P6_3cm$ to space group $P6_3$ due to a triple-helix like arrangement of the water molecules within the channels [1]. It is known from X-ray powder refinements at 385 K [2], that the framework of VPI-5 exhibits a strong anisotropic thermal behaviour. This is caused by a temperature induced disordering of the water molecules within the channels, which allows the re-establishing of the higher framework symmetry. The refinement of the structure of VPI-5 at 295 K with a = 19.985(3) Å and c = 8.119(2) Å confirmed for the framework geometry the results of a former single crystal investigation [3], however, there is a clear difference in the occurrence of two new sites for water molecules. Concerning the previously described water positions [1] the two water sites OW5 and OW7 were not occupied in this single crystal material, thus preventing the establishing of the triple-helix. The unit cell of the low temperature form of VPI-5 with a = 19.978(3) Å and c = 8.052(2) Å shows a pronounced shortening along [001], which is in accordance to the trend of the partially dehydrated form [2]. This shrinkage increases the deviation from the ideal symmetry, which at 90 K is mainly caused by the framework and minor by the water molecules.

P09.09.007 A SPECTROSCOPIC STUDY ON STRUCTURE CONTROLLING PARAMETERS IN ORGANOTHERMAL SYNTHESES OF CANCRINITE. B. Posnatzki, M. Fechtelkord and J.-Chr. Buhl, Institut für Mineralogie, Universität Hannover, Welfengarten 1, D - 30167 Hannover, Germany

The zeolite-like mineral cancrinite $Na_8[AlSiO_4]_6X^{2-}\ nH_2O$ is a promising material for future technical applications. Its characteristic structural feature is a single 12-ring channel parallel to the c-axis [1]. This one-dimensional channel system with a diameter of about 6.8 Å is a perfect matrix for the enclathration of orientated molecules [2, 3]. The insertion of organic macromolecules as reactive compounds for later catalytic reactions is possible, as well as the incorporation of small organic molecules that can be removed by heating.

In conventional syntheses cancrinite is prepared under hydrothermal conditions in systems consisting of Na_2O-SiO_2-Al_2O_3-H_2O in the presence of a large variety of salts [4]. These cancrinites contain inorganic anions that are blocking the pores and prevent a technical utilisation as defined by a zeolite.

During synthesis in non-aqueous solvents the nature of Al-, Si-source, solvent, base and the temperature has a large influence on the formation of the desired product. Investigations of these structure controlling parameters and of the calcination process were made by various methods of analyses, like NMR- and IR-spectroscopy, as well as X-ray powder diffraction and thermal analysis. Different Al_2O_3 - SiO_2 - sources were employed. Best results were received by application of sol-gels of various compositions; 1,3- and 1,4-butane-diol are the solvents used. The calcination process plays an important part in improving the sorption capacity of the material. Therefore several calcination methods were checked like thermal and chemical treatment.

P09.09.008 TETRATHIAFULVALENE AND TETRA-CYANO-P-QUINODI-METHANE IN FAUJASITE. C. Baehtz, H. Fuess, Materials Science, Darmstadt University of Technology, Petersenstr. 23, D-64287 Darmstadt, Germany

The last few years have seen an increasing interest in host-guest-systems with zeolites because their chemical and physical properties [1]. We are focusing on the systems Tetrathiafulvalene (TTF) in Faujasite NaY, Tetracyano-p-quinodimethane (TCNQ) in NaY and the charge-transfer-complexe TTF and TCNQ in NaY, which have been investigated by powder-diffraction, DRIFT-,UVVIS- and EPR-spectroscopy.

The guest molecules are incorporated in the host lattice by adsorption from the liquid-phase. The solvent is removed by heating under high vacuum. Powder diffraction pattern with synchrotron radiation with λ=1.16Å at 10 K and CuKα1-radiation at 293K exhibit considerable differences of intensities as compared to the unloaded host. The localisation of the guest is performed through a determination of the rest electrondensity by Fourier analysis and subsequent Rietveld refinement. The TCNQ molecule is in the center of the 12-ring window while the CN-groups mount into the two neighbouring supercages and are coordinated by the SII* sodium ions. DRIFT measurements of TCNQ in NaY show a CN-signal shifted to higher wavenumbers as in the pure TCNQ spectra. In the case of the charge-transfer-complexe in NaY, this signal is split into two peak at lower wavenumbers. Due to the arrangement of TCNQ in the host and the coordination of the functional groups to the sodium ions, strong interactions between the lattice and the guest molecules result. This explains the strong and broad EPR-signal and the shifted UVVIS-absorption bands.

P09.09.009 POWDER NEUTRON DIFFRACTION AND ^{13}C MAS NMR STUDIES OF NAY ZEOLITES WITH CHEMISORBED METHYL GROUPS. S. Vratislav, M. Dlouhá, Faculty of Nuclear Sciences and Physical Engineering, Břehová 7, 115 19 Prague 1, Czech Republic, and V. Bosáček, Heyrovský Institute of Physical Chemistry, Dolejškova 3, 182 23 Prague 8, Czech Republic.

Zeolites exhibit regular structure which can be easily modified and therefore are important candidates for effective catalysts [1].

The crystal structure of NaY zeolite with chemisorbed methylium ion have been investigated by powder neutron diffraction on the KSN-2 diffractometer which is placed at the LVR-15 research reactor in Řez near Prague. Structural parameters were determined by Rietveld analysis of powder neutron patterns (collected at 7 K) using the GSAS package. Difference Fourier maps were calculated to localize the nonframework cations and the CD_3 groups. Experimental evidence of the created chemisorbed methyl groups after reaction of methyliodide with Na+ cations of the zeolite was obtained from ^{13}C MAS NMR spectra [2].

Our studies of chemisorbed NaY zeolites show that chemisorbed CD_3^+ groups are preferentially located in alfa cages at O(l) oxygen sites. A complete set of the structural parameters in the frame of Fd3m space group for unperturbed NaY and for NaY after the formation of surface methoxy groups (a = 2.4897(8) nm, R_{wp} = 0.0712, R_p = 0.0568) were given and an influence of chemisorbed species on the distribution of Na^+ cations in the lattice was detected by neutron diffraction [3]. While the occupation of S_{II} in NaY without adsorbate was 32 Na^+ per unit cell (i.e. 100%), after the chemisorption of CD_3I was found 21.4 (67%).

P09.09.010 LOCATION OF BRØNSTED SITES IN D-MORDENITES BY NEUTRON POWDER DIFFRACTION. G. Cruciani and A. Martucci, Istituto di Mineralogia, University of Ferrara, Ferrara, Italy

Neutron Rietveld refinements of one natural mordenite (Si/Al=5.4) and two synthetic mordenites (Si/Al=5.6 and 10.0) in their deuterium form were performed in the *Cmcm* space group.

From the structure refinements four Brønsted acid sites were recognized. The first, D1, was on framework oxygen O10 and headed towards the center of the 12-ring; the second, D2, was on the framework oxygen O6 and headed towards the side pocket; the third, D3, was on O5 and, as D1, headed towards, the center of the 12-ring; the last, D4, was on O9 and headed toward the center of the 8-ring. The T-O distances involving the Brønsted sites were always among the largest T-O distances of the tetrahedra, thus confirming the correct location of OD groups. The deuterium sites had occupancies varying in the range 7-24%, with the O6-D2 group always showing the highest occupancy. All the OD groups show regular site geometry, and about half of the theoretical value of Brønsted sites (calculated on the basis of the aluminum content) has been localized. This result can be explained considering that, in the case of elevated Al content, the concentration of Brønsted sites is remarkably lower than would be expected on the basis of the aluminum content [1,2,3]. On the whole about half of the acid sites vibrate in the 12-ring channel, and half in the smaller channels. Few other extraframework sites, with low occupancy and at large distances from the framework oxygens, have been attributed to residual ND_4 groups.

P09.09.011 STRUCTURE REFINEMENTS OF CO-FERRIERITES. M. C. Dalconi and G. Cruciani, Istituto di Mineralogia, University of Ferrara, Italy.

The catalytic reduction of nitrogen oxides (NO_x) in the presence of excess oxygen is now one of the most important subjects from the viewpoint of environmental protection. Li and Armor (1) recently showed that Co^{2+}-exchanged ferrierite is a particularly active catalyst for the reduction of NO_x with methane in the presence of excess oxygen.

This study is devoted to clarifying the structural modifications undergone by ferrierite when loaded with increasing amounts of Co cations.

Room temperature synchrotron X-ray diffraction data were collected on three samples of Co-ferrierite ion-exchanged with different amounts of Co. Rietveld structure refinements were performed by the GSAS package. Assuming the framework composition of the as-synthesised zeolite (Engelhard), we found that the Co^{2+}, Na^+ and K^+ cations in the Co-Fer.1S sample were not enough to counterbalance the framework charge.

The remainder of the charge is probably compensated by the presence of Brønsted acid sites produced during thermal decomposition of the residual NH_4^+ cations (2), and/or by residual NH_4^+ cations themselves (as indicated by IR analysis). In the case of the Co-Fer.3S sample the ion-exchange appear to be complete. The over-loaded Co-Fer.7S was completely ion-exchanged, and the excess of cobalt is probably located in an unidentified second phase outside the framework. The structure refinements of the three samples were performed using the space group *Immm*; there was no evidence for a lowering of symmetry to $P2_1/n$. The restoration of the apparent topological symmetry *Immm* was attributed to the presence of the $Co(H_2O)_6^{2+}$ octahedron in the large ferrierite cage. In all three samples Co^{2+} was seen to be coordinated to six water molecules in a regular octahedral configuration at the centre of the ferrierite cage.

10. CRYSTALLOGRAPHY IN MATERIAL SCIENCE

P05.10.001 SUPERIONIC TRANSITIONS IN THE $KTiOPO_4$:Nb CRYSTALS. T.Yu.Losevskaya, V.I.Voronkova, and V.K.Yanovskii, Department of Physics, Moscow State University, Moscow 119899, Russia.

The $KTiOPO_4$ (KTP) and other crystals of this family are well known as excellent active elements for non-linear optical applications. At the same time they are of great scientific interest as representatives of a new specific variety of solid state materials, namely, ferroelectrics - superionics in which phenomena of electrical ordering combine with anomalous high ionic conductivity. The latter is attributed to the presence of movable alkaline or thallium cations in the wide channels along c-axis of the KTP-type structure and can be changed by way of heterovalent substitutions. On the other hand from previous investigations it follows that the conductivity of KTP crystals has a monotonous temperature dependence without any pronounced anomalies characteristic of many ordinary superionic crystals. The present study shows for the first time that large jumps of conductivity may be observed in the KTP crystals doped with niobium.

The crystals studied were grown with the use of flux method from the melts with the substitutions of 3-60 at.% of Ti by Nb with the slow cooling within temperature interval of 900 to 750ºC. As a rule the crystals had dimensions of order of several mm and week brown coloration which can be eliminated by heating in air atmosphere at 800-900ºC. The samples for conductivity studies were cut in the form of plates perpendicular to crystallographic axes and were supplied with silver electrodes. Measurements were made at the frequency of 1 Mc with the bridge Tesla BM 431E.

The conductivity jumps which are typical of superionic transitions were observed along c-axis in the crystals grown from the melts with 6-8 at.% Nb. Their value ranges up to 3 orders of magnitude depending on the crystal composition and thermal history. Temperature of such the jumps lies in the region from 20 to 400ºC and can vary up to several tens of degrees from one measurement to another for the same specimen. No noticeable changes were found in the crystal structure at these transitions so they seem to have a pure electronic nature.

P05.10.002 PHASE TRANSITIONS AND PHYSICAL PROPERTIES OF THE $K_3Nb_3B_2O_{12}$ CRYSTALS AND THEIR SOLID SOLUTIONS. E.P.Haritonova, V.I.Voronkova and V.K.Yanovskii. Department of Physics, Moscow State University, Moscow 119899, Russia.

$K_3Nb_3B_2O_{12}$ (KNB) crystals attract attention as new interesting solid state materials with the unusual combination of ferroelectric, antiferroelectric, ferroelastic and superionic properties. The main aim of the present work were growth of the KNB single crystals, pure and doped with Na and Ta, and the study of their phase transitions and physical properties.

Because of incongruent melting the KNB crystals with the sizes up to 2 cm were obtained by way of flux growth from the melts in the systems $K_2O(Na_2O)$-B_2O_3-$Nb_2O_5(Ta_2O_5)$. They had the appearance of colorless transparent hexagonal prisms with the well developed faces of prisms of the first and second type, hexagonal pyramid and pinacoids.

As follows from the x-ray analysis and investigations of optical and electrophysical properties the KNB crystals exhibit a complex sequence of phase transformations at 470, 400, 110, -85 and -97ºC. The diffuse transition at 470ºC with the large anomaly of dielectric permeability seems to be antiferroelectric with the appearance of antipolarization along the c-axis and multiplication of elementary cell, whereas the transition at 110ºC has ferroelectric nature. Other transitions are manifested in the formation of domain structure with the domain walls along $\{10\bar{1}0\}$ and $\{11\bar{2}0\}$ planes and in the changes of optical axes orientation and interference colors. At the room temperature the crystals show ferroelastic properties.

Partial substitution of K by Na increases the temperature of ferroelectric transition and decreases that of antiferroelectric transition. In the Ta doped crystals all the transitions became more diffuse and their temperature decreases. So, the temperature of ferroelectric transition in the crystals with 30 at.% Ta lies below 20ºC.

Electrical conductivity of the KNB crystals is found to be mainly ionic and has the value of order of 10^{-5} $Ohm^{-1}cm^{-1}$ at the room temperature. Phase transformations at 400 and especially 470ºC are followed by the conductivity jumps typical of superionic transitions.

P05.10.003 OPTICAL ROTATION IN THE LOW TEMPERATURE PHASE OF K_2ZnCl_4. D.-Y. Kim and W. Kaminsky, Clarendon Laboratory, University of Oxford, Parks Road, Oxford OX1 3PU, UK.

The recently developed 'tilter' method [1] was successfully utilized to measure the optical rotation and linear birefringence of K_2ZnCl_4 (KZC) in the temperature range between 50 K and 290 K. KZC exhibits a ferroelectric - ferroelastic phase transition from SG $P2_1cn$ to $C1c1$ at T_c = 145K [2]. In the room-temperature phase only the optical rotation component ρ_{12} is allowed by symmetry (The physical reference system is $\mathbf{x} // \mathbf{a}_3$, $\mathbf{y} // \mathbf{a}_2$, $\mathbf{z} // -\mathbf{a}_1$). Below T_c, a second component ρ_{23} arises as a result of the monoclinic symmetry.

Because there is a chiral lock-in modulation along ca. [110] in KZC due to the low-temperature super-structure [3] (this is along the diagonal between the y- and z-axis), we expected to observe an increase in optical rotation in the component ρ_{23}. Calculations with the dipole-dipole model [4] resulted in a jump of optical rotatory power of about 3 degrees/mm at 100K. Significantly increased optical rotation below T_c was indeed experimentally detected in ρ_{23}. The observed rotation showed a discontinuity of about ±2 degrees/mm at T_c and exchanged signs between different temperature runs as a result of domain formation. ρ_{12} seems to be less affected by the transition. The absolute values of birefringence measured as well, confirming an earlier observation which showed only the relative changes [5].

P05.10.004 REAL STRUCTURE OF WO_3 CRYSTALS. O. Goncharova, K. Abdulvakhidov, M. Kupriyanov, Rostov State University, 5 Zorge, Rostov-on-Don, 344090, Russia.

Comprehensive structural characterization of ferroelectric single crystals performed by different x-ray diffraction methods seems to be a powerful method of testing possible microscopic mechanisms responsible for the changes in their physical properties under various external conditions.

In this work we studied the changes of real structure of antiferroelectric WO_3 crystals under constant electric fields.

The structural studies of the plate – like crystals by x-ray diffraction (HZG-4B diffractometer, CuKα radiation) included an investigation of domain and block structures and the peculiarities of the structural changes under electric fields. We studied twinning effects determined the lattice parameters and diffraction

effects affected by surface layers of crystals by measuring the x-ray scattering intensity distributions $Y(2\theta,\omega)$ near Bragg reflections and the changes of such distributions under electric fields by using a special device with electrodes transparent to x-rays.

Some new results obtained for WO_3 structure changes under different regimes of electric field application (field heating , field cooling) will be presented.

P05.10.005 CHANGES AT ATOMIC LEVEL IN DKDP UPON APPLICATION OF AN ELECTRIC FIELD. S.J. van Reeuwijk and H. Graafsma, European Synchrotron Radiation Facility, Avenue des Martyrs, 38043 Grenoble, France, P.H. Zwart, Laboratory of Crystallography, University of Amsterdam, The Netherlands.

The piezoelectric crystal DKDP, the 98% deuterated isomorph of KDP, potassium dihydrogen phosphate, undergoes structural changes upon application of an external electric field. The structural changes manifest themselves as 1) changes in unit cell parameters, giving rise to a shift of the reflection in direct space, and 2) changes in the electron density (atomic positions and polarisations), giving rise to a change in the diffracted intensity.

At the newly developed set-up at ID15C at the ESRF, a 0.3 mm thick, plate like and c-cut DKDP crystal was mounted on a 4-circle diffractometer. The faces of the crystal were covered with Al electrodes. Electric fields up to $1.3\cdot10^6$ V/m were applied parallel to the crystallographic c-axis.

From the relationship between the shift of the reflection due to the applied electric field and $\tan\Theta$ the d_{36} piezoelectric constant at room temperature was determined to be 52(2) pC/N, which is close to values reported in literature [1].

Due to the applied electric field the space group changes from I_{-42d} to F_{dd2}. Reflections *hkl* and *khl*, symmetry equivalents in space group I_{-42d}, are not related by symmetry in space group F_{dd2}.

The relative change in integrated intensity, $\Delta I/I$, was measured for 35 reflections. Merging the reflections, where R_{merge} = 23.09%, resulted in 11 unique reflections. The broken symmetry is clearly present in the data: $\Delta I/I$ for *hkl* differs significantly from $\Delta I/I$ for *khl*. The data are currently used to determine the changes in the atomic positions upon application of an electric field. The results of this refinement will be presented.

P05.10.006 TENSOR DISTINCTION OF DOMAIN STATES. V. Kopský, Institute of Physics AV CR, Na Slovance 2, 182 21 Praha 8, Czech Republic.

The phenomenon of the splitting of a material which undergoes a ferroic phase transition into domains is well know. Domains are distinct regions in the ferroic phase which are completely identical up to their orientation in space. The point symmetry of each domain is one of the set of conjugate subgroups F_i and its tensor properties are different with reference to the same co-ordinate system. The distinction between these properties is the first step in the consideration of boundary effects at interfaces of domain pairs. The numbers of independent tensor components in which domain states of pairs differ are available in the recent literature up to fourth rank tensors. We shall demonstrate tables from which explicit tensor components can be found which are either common to the pair or in which the pair differs. The solution is seen immediately in cases of the completely transposable domain pairs where the differing components have an opposite sign; other cases need further elaboration of the provided results. The tables will constitute a part of a software which is to be released as an appendix to *Vol. D: "Physical Properties of Crystals"* of the *International Tables for Crystallography* series. The components of the following tensors characterised by Jahn symbols are considered: enantiomorphism (chirality) ε, spontaneous polarization V and deformation (or permittivity) $[V]^2$, optical activity (gyrotropy) $\varepsilon[V]^2$, piezoelectricity (electro-optics) $V[V]^2$, electrogyration $\varepsilon V[V]^2$, linear elasticity $[[V^2]^2]$, and piezo-optics (electrostriction) $[V^2]^2$. Tables include also the explicit form of the electric and elastic switching interactions. The scheme is at the moment developed for the ordinary point groups but the extension to the magnetic point groups where domain pairs will be distinguished also by tensors which reflect magnetic effects is a matter of routine application of the same methods. The software is also a first step of a project of Group Informatics the aim of which is the standardisation and computerisation of group theoretical procedures.

P05.10.007 STRUCTURAL STUDY OF THE FERROELECTRIC AND PARAELECTRIC PHASES OF $PbNb_2O_6$. W.F. Reeve, Department of Physics. Clarendon Laboratory, University of Oxford, Parks Road, Oxford OX1 3PU, UK.

The structure of lead niobate ($PbNb_2O_6$) has been investigated using both synchrotron X-ray single crystal diffraction and neutron powder diffraction data.

Lead niobate is an industrially important ferroelectric that possesses a tetragonal tungsten bronze type structure. Previous structural studies had been limited to that of Labbé et al. [1] who deduced the prototype structure. For this study the single crystals have been grown by the flux method. The X-ray experiments have been carried out on the single crystal diffraction station at the Daresbury laboratory synchrotron light source in the U.K. This station is equipped with an area detector, which combined with the intense radiation from the synchrotron has allowed diffuse scattering from $PbNb_2O_6$ crystals to be observed.

Data collections at room temperature and above the Curie temperature of 840K have been undertaken. The room temperature phase is orthorhombic with lattice parameters a=35.292(3)Å, b=17.948(2)Å, c=7.736(1)Å, space group $Bb2_1m$. Both occupational and displacement disorder of the Pb atoms are present in the structure and from the study of the diffuse scattering patterns, short-range ordering models are presented. The high temperature phase is tetragonal with lattice parameters a=b=12.696(2)Å, c=3.880(1)Å, space group P4/mbm.

This work, coupled with powder neutron diffraction experiments at the ILL, France, has allowed accurate structural models for this material to be refined.

P05.10.008 STRUCTURE REFINEMENT OF AN AURIVILLIUS PHASE $Bi_5Ti_3FeO_{15}$ USING NEUTRON POWDER DIFFRACTION. T. Ko, Department of Ceramic Engineering, Inha University, 253 Yonghyun-dong, Nam-gu, Incheon, Republic of Korea and J. Lee, Korea Atomic Energy Research Institute, 150 Dukjin-dong, Yusong-gu, Taejon, Republic of Korea.

$Bi_5Ti_3FeO_{15}$ is a compound which has commensurate displacive modulations of constituent atoms in Bi_2O_2 layers and perovskite structural units. The room temperature structure[1] of this compound has been reported to have a space group of *F2mm*. However, our neutron powder diffraction revealed that some weak reflections would violate *F*-centering. Since the former study[1] was carried out using X-ray diffraction, it might not be possible to observe such weak scattering essentially from oxygen atoms. In this study, a diffraction measurement of $Bi_5Ti_3FeO_{15}$ was measured at HRPD of HANARO, which is a newly constructed research reactor in the Republic of Korea, with a constant wavelength of 1.8339 Å and a step scan of 0.05 deg using 32 multi-dectectors covering 0 ~ 160 deg. A Rietveld refinement

with a space group of $A2_1am$ was converged at R_p = 5.69%, R_{wp}= 7.36% and S = 1.715 for an isotropic temperature model with 59 variables. In contrast, with the space group of *F2mm*, the refinement was not successful. We observed that with the space group of $A2_1am$, the octahedra of transition metal atoms become tilted in a modulation mode of *Amam,* which is a soft mode related to the rotation of the octahedra about a polar *a* axis. This may create a rather coherent distribution of Bi-O distances in the perovskite units, compared to those of *F2mm*. Besides, a Fourier map shows that electron density is completely absent at Ti and Fe atom sites, suggesting that their atoms are disordered. For Bi atoms of the Bi_2O_2 layers, Bi –O distances of the layers are much shorter than the distances of the Bi atoms to the nearest apical oxygen atoms of the octahedra of the perovskite units. These Bi environments are highly asymmetric showing the effect of a lone pair of electrons.

P05.10.009 CHANGE OF SURFACE MORPHOLOGY WITH THE STRUCTURAL PHASE TRANSITION IN $BaTiO_3$ SINGLE CRYSTAL. S.Doi and I.Takahashi, Advanced Research Center of Science (ARCS), School of Science, Kwansei Gakuin University, Sanda 669-1337, Japan

The emergence of self-organized structures on surfaces, triggered by the phase transition or generated in the crystal growth process, is a very surprising phenomenon we often encounter. These intriguing structures are commonly characterized by the spatial and temporal *pattern formation*.

Dielectric substances, which generally turn into a complex polydomain structure at the structural phase transition, could be analogous to the above systems. In the dielectric crystal, since the average size of domains is small, say, in '*mesoscopic*' length scale in the vicinity of transition temperature T_c, the domain configuration is subject to thermal excitation, external electric field or stress, and fluctuations of order parameter. In the case of perovskite-type crystals which exhibit a variety of phase transitions such as ferroelectric or ferroelastic transition, a typical '*a-c*' 90°domain structure arises and the occurrence and temperature evolution of this domain arrangement affect directly on the surface morphology. Therefore, a unique pattern of surface morphology and a surface critical behavior with the phase transition induced by various fluctuations could be observed with varying temperature.

We investigated the morphology of $BaTiO_3$ (001) surface through the cubic-tetragonal phase transition by using the X-ray reflectivity (XR) technique, which is sensitive to surface structure at wide spatial length scale. We obtained information on the domain structure of crystal surface from XR peak profiles, like as the change of Bragg diffraction pattern due to the domains in bulk. We will report in detail about novel aspects of the surface behavior as compared with the bulk.

P05.10.010 STRUCTURES OF DEUTERATED FERROELECTRIC TRICHLOROACETAMIDE AS STUDIED BY NEUTRON POWDER DIFFRACTION. M. Hashimoto, S. Matsumoto, M. Ozawa, Department of Chemistry, Faculty of Science, Kobe University, Nadaku Kobe 657-8501, Japan Y. Kamishina, Faculty of Education, Shimane University, Matsue 690-8504, Japan,T. Kamiyama, Institute of Materials Science, University of Ttsukuba, Tsukuba, Ibaraki 305-8573, Japan, and F. Izumi, National Institute for Research in Inorganic Materials, Ibaraki 305-0044, Japan

Phase III of trichloroacetamide (Cl_3CCONH_2, TCAA) undergoes a ferroelectric transition at 354.6 K (ca.353K for Cl_3CCOND_2, TCAA-d) to give phase II, which is transformed into phase I at 356.9K[1]. At the high temperatures the X-ray work was difficult owing to vigorous sublimation of the compound. In the present work the crystal structures of TCAA-d at 90, 300, 343 K (phase III) and that at 370 K (phase I) were investigated by neutron powder diffraction method. The crystal data at 300 K [those at 370 K]: monoclinic [monoclinic], space group $P2_1$ [$P2_1$], a=1041.13(4) [1046.48(7)], b=578.41(2) [581.87(3)], c=1017.30 [1021.77(8)] pm, β=107.616(3) [107.611(2)] degrees. The structural changes due to the phase transitions were found to be quite subtle. A small angle reorientation of the CCl_3 group in one of the two independent TCAA-d molecules is likely to be accompanied by the phase transition(s). One of the four N-D...O hydrogen bonds in phase III seems to include a weak N-D...Cl interaction.

P05.10.011 EVEN AND ODD EFFECT IN STRUCTURE OF $C_nH_{2n+1}NH_3H_2PO_4$ CRYSTALS. H.Kasatani, Department of Materials Science, Shizuoka Institute of Science & Technology, 2200-2 Toyosawa, Fukuroi, Shizuoka 437-8555, JAPAN, and H.Terauchi, Advanced Research Center of Science & School of Science, Kwansei-Gakuin University, Sanda, Hyogo 669-1337, JAPAN, and M.Iwata and Y.Ishibashi, Department of Applied Physics, School oh Engineering, Nagoya University, Chikusa-ku, Nagoya 464-8601, JAPAN.

The title new compounds of *n*-alkyl ammonium dihydrogen phosphate, ($C_nH_{2n+1}NH_3H_2PO_4$, abbreviated as C_nADP), with 1-9 and 12 have unique properties; such as ferroelasticity, successive phase transitions and even and odd effect[1]. The x-ray single crystal structure analyses of C_nADP with n=2-6 were carried out at room temperature in order to clarify the even and odd effect[2,3]. The crystal system of these compounds was monoclinic system and the space group was $P2_1/n$(Z=8). The characteristics of these crystal structures were that the anti-parallel planner organic chains ($C_nH_{2n+1}NH_3$) were along *b*-axis, and the inorganic PO_4 tetrahedra were bonded by ordered H-atoms in *b*-plane. On the other hand, two different points for these crystal structures were observed. One was the difference of the molecular kind on 2_1-screw axis. Another was the difference of the packing pattern of the methyl group of the end parts in the anti-parallel planner organic chains. It is thought that these differences on crystal structure were related to the even and odd effect.

P05.10.012 A STUDY OF THE FREQUENCY DEPENDENCE OF THE DIELECTRIC MAXIMUM IN PMN-PT CERAMIC. V. K. Wadhawan, Gurvinderjit Singh and V. S. Tiwari, Laser Materials Laboratory, Centre for Advanced Technology, Indore 452 013, India

We have synthesized (by the coulombite route) the relaxor-ferroelectric ceramic PMN-PT ($PbMg_{0.3}Nb_{0.6}Ti_{0.1}O_3$). Processing conditions were optimized to achieve 95% of the theoretical density for the ceramic. The material was investigated for its dielectric behavior at various temperatures and frequencies. The maximum relative dielectric constant obtained by us is 18000 at 1 kHz. Polarization hysteresis behavior was also studied in a wide temperature range, as also the electric-field-induced strain. As expected for a relaxor ferroelectric, the real part of the dielectric constant showed a maximum (ε_m) at a characteristic temperature T_m, and ε was found to obey the equation $1/\varepsilon = 1/\varepsilon_m [1+(T-T_m)^{\gamma}/2\delta^2]$. The parameters γ and δ exhibit a parabolic dependence on the probing frequency (for the range 100 Hz to

100 kHz). The observed dielectric relaxation times were found to be best explained by the equation $\tau = (\omega_0)^{-1} \exp[T_0/(T_m-T_f)]^p$. The `best-fit' parameters are: $\omega_0 = 3.6 \times 10^8$ Hz, $T_0 = 172$ K, $T_f = 179$ K, and $p = 12.76$. The introduction and use of this equation by us [which is a modification of the equation used by Cheng et al. (*J. Appl. Phys*., **79**, 8615 (1996))], is an improvement, in the sense that we do not assume that $T_f = 0$; only for a Debye solid can T_f (the freezing temperature) be zero.

P05.10.013 SEPARATING LEAD(II) FROM BISMUTH(III) IN METAL OXIDES BY ANOMALOUS DISPERSION METHODS. Brendan J. Kennedy, School of Chemistry, The University of Sydney, Sydney, NSW 2006, Australia.

Lead(II) and bismuth(III) are isoelectronic and contain 6s electrons that can exhibit sterochemical activity. The similarity of the structural requirements of Pb(II) and Bi(III) leads to the possibility of disorder of these cations over available sites, which can be difficult to detect using "chemical knowledge". PbBi2Nb2O9 is an important ferroelectric oxide that adopts a two-layer Aurivillius structure, where the Pb is in the perovskite type blocks that are separated by (Bi2O2) layers. Thermal treatment of this oxide alters the ferroelectric properties of this material and the cell volume and these observations offer indirect evidence for site disorder, where some of the Pb is located in the (Bi2O2) layers. Powder neutron studies apparently confirm the presence of such disorder however since Pb and Bi have similar neutron scattering lengths the results were less definitive than anticipated.

In the present presentation we describe the use of anomalous dispersion methods to quantify the Pb/Bi site disorder in PbBi2Nb2O9. High quality powder diffraction data was collected, using synchrotron radiation, above and below both the Pb and Bi L(III) edges. The structure was then refined using these data, together with powder neutron diffraction data, by the Rietveld method. Attempts to chemically control the extent of disorder through doping of the oxides with Sr or Ba will also be presented.

P05.10.014 PHASE DIAGRAMS AND CORRES-PONDING PROPERTIES OF ISOMORPHOUS CRYSTALS $CH_3NH_3\ Bi_2X_{11}$, X = Cl Br. E.S.Larin and Yu.M.Gufan, North Caucacian Scientific Centre,344006 Rostov on Don, Russia, and K.Gesi, Department of Material Science , Ivaki, Fokushima, 970-8551, Japan .

Two members of a rich family of alkilammonium halogenobismuthate crystals suffer successive phase transitions (PT) with the same changing of symmetry D_{2h}^{15} - C_{2v}^5 - C_{2v}^5 - C_2^1. Both compounds crystallized in the form of pseudohexagonal prism. It suggests the idea that theirs parent phase (PPh) is characterized by the hexagonal symmetry. The (PPh) approximation (PPhA) represents the first step of perturbation theory in the framework of Landau Theory (LT) of PT . The actual one-component order parameter (OP) describing PT C_{2v} – C_2 in the PPhA becomes two- component (e_1 e_2) ferroelastic OP , which insert the third order invariant in the Landau potential. According the theory, basing on Landau Potential, $F = A_1P_z^2 + A_2P_z^4 + a_1I_1 + a_2I_1^2 + a_3I_1^3 + b_1I_2 + b_2I_2^2 + +c_{12}\,I_1\,I_2$ (Here $I_1 = c_1^2 + c_2^2$, $I_2 = e_1^3 + 3e_1e_2^2$) the isostructural PT C_{2v}^5 - C_{2v}^5 exists as a natural consequence of the third – order invariant in the Landau potential. On the basis of the LT with two interacting OP's (ferroelastic two-components) and ferroelectric (Pz) we constructed the phase diagram and defined the thermodynamic paths , which are proper for $(CH_3NH_3)_5Bi_2X_{11}$ (X=Cl (MAPCB) or Br (MAPBB)). The MAPBB's path crosses the line of IPT and path of (MAPCB) crosses the trace continuing IPT after critical endpoint. The corresponding differences in dielectric and elastic modulus anomalies for these two compounds, originate from the differences of theirs thermodynamic paths. In this research the complete set of dielectric susceptibilities, elastic modulus and lattice constants dependencies on the temperature are estimated in the framework of LT basing on the PPhA. We are grateful to Russian Fund of Basic Researches for financial support .

P05.10.015 EFFECT OF LAYER BISMUTH COMPOUNDS IN RELATION TO THE STRUCTURAL MODIFICATION OF FERROELECTRIC $BaTiO_3$. Sujata Mazumdar, Central Glass & Ceramic Research Institute, 196 Raja S.C.Mullick Road, Calcutta- 700032, INDIA

Ferroelectric $BaTiO_3$ with certain structural modification is considered for special application in electronic industry [1]. Modifiers chosen for present study are primarily perovskite like layered bismuth componds [2] with general formula $(Bi_2O_2)^{2+}$ $(A_{m-1}B_mO_{3m+1})^{2-}$ where A is a combination of ions adequate for twelve coordinated interstices, B is a combination of ions adequate for octahedrally coordinated sites and m is an integer between 1 & 7. The crystallo-chemical study for the choice of metal ions in A and B of the original lattice have been done. The stability of the structure is lost by dimensional mismatch between perovskite layer and bismuth oxide layer. Based on the theory that site potentials of oxygen ions in an oxide perovskites are more or less same, combination of $BaTiO_3$ as well as modifier perovskites can easily produce either a chemical homogenity or controlled chemical heterogenity within the structure under suitable experimental condition. The results of the x-ray analysis on the determination of structures of modified $BaTiO_3$ has been discussed in order to establish the structure-dielectric property correlation.

P05.10.016 STRUCTURAL AND MAGNETIC PROPERTIES OF $(Fe_{1-x}Mn_x)_3P$ COMPOUNDS. Hui-ping Liu,[1] Y.Andersson,[1] P.James,[2] O.Eriksson[2] B.Kalska[2], L.Häggstöm[2], A.Broddefalk,[3] P.Granberg,[3] and P.Nordblad[3], [1]Dept. of Inorg. Chem., Box 538, S-751 21, Uppsala University, Sweden, [2]Dept. of Physics, Box 530, S-751 21, Uppsala University, Sweden, [3]Dept.of Materials Science, Box 534, S-751 21, Uppsala University, Sweden

In $(Fe_{1-x}Mn_x)_3P$ system, the tetragonal Fe_3P-type structure [1] predominate. The substitution range of Mn for Fe on the Fe-rich side was found to be $x < 0.25$, which is less than the previous reported 0.3 [2], while on the Mn-rich side, it was found to be $x > 0.65$.

The structural and magnetic properties of $(Fe_{1-x}Mn_x)_3P$ compounds have been investigated by means of X-ray and neutron powder diffraction experiments, magnetisation measurements, Mössbauer Spectrum and first principles calculations. The substitution of Fe with Mn leads to an enlargement of the crystal unit cell, since the radius of Mn is larger than that of Fe. The occupancies and magnetic moments on the three non-equivalent metal sites are determined. Results show that Mn preferentially substitutes Fe on two of the metal sites. The magnetization measurements on the Fe-rich side indicate that the compounds order ferromagnetically below the Curie temperature. Both the saturation magnetisation and T_c decrease with increasing Mn content. But on the Mn-rich side, antiferromagnetic ordering lowers the magnetic moments significantly. Both the moments and T_N drop with the Mn concentration. Pure Mn_3P posses a very small net magnetic moment, the T_N was found around 35 K which is not consistent with the previous reported $M_{Mn} = 1.68\mu_B$, $T_N = 115$ K [3].

P05.10.017 CRYSTAL STRUCTURE AND DIELECTRIC RELAXATION STUDIES IN $[N(CH_3)_3H]_3Sb_{2(1-x)}Bi_{2x}Cl_9$ (TMACAB). J. Zaleski and G. Bator Institute of Chemistry, University of Opole, Oleska 48, 45-951 Opole, Poland Faculty of Chemistry, University of Wrocław, Joliot-Curie 1450-383 Wrocław, Poland

$[N(CH_3)_3H]_3Sb_2Cl_9$ (TMACA), ferroelectric at room temperature, belongs to the family of alkylammonium halogenoantimonates(III) of the general formula $R_aSb_bX_{(3b+a)}$ (R - alkylammonium cation, X - chlorine, bromine or iodine) [1].

The crystal structure of TMACA is characterised by the two-dimensional layer structure of polyanions [2]. In the ferroelectric phase there are three non-equivalent $NH(CH_3)_3^+$ cations in the crystal structure . Two of them, placed between the layers, are ordered while the third one, located inside a voids of the anionic sublattice is disordered.

The dielectric response in TMACA around $T_c = 364$ K exhibits features typical of a para-ferroelectric phase transition. The macroscopic dielectric relaxation time in the paraelectric phase in TMACA shows "critical slowing down" close to T_c.

It is well known, that the physical properties of the crystals may be modified by the exchange of the metal atoms (Sb→Bi) in the crystal lattice. A strong influence on the value of ε (a drastic reduction) at the phase transition and a shift of T_c toward higher temperature, with the increase of the Sb contents was found e.g. in the $[CH_3NH_3]_3Bi_{2(1-x)}Sb_{2x}Cl_{11}$ [3].

In the present contribution we present results of the investigation of the influence of the metal atom replacement on the structure and dielectric properties of the mixed $[N(CH_3)_3H]_3Sb_{2(1-x)}Bi_{2x}Cl_9$ (TMACAB) crystals. The determination of the phase diagram, for TMACAB is interesting from the point of view of possible technical applications and particularly, the recognition of the influence of the concentration of impurities on the dynamical properties of these crystals.

P05.10.018 PHASE TRANSITION AND STRUCTURE OF $K_2Fe(SO_4)\cdot 2.2H_2O$. H. Ishigami, M. Sumita [1], S. Sato [2], T. Hikita [3], [1] Faculty of Engineering, Shibaura Institute of Technology, [2] X-ray Research Laboratory, Rigaku Corporation, [3] School of Engineering, Tohoku University

$K_2Fe(SO_4)\cdot 2.2H_2O$ shows anomalies of specific heat and electric susceptibility at 364 K [1]; structural details were not reported so far. Very recently we have determined the crystal structure of the compound at 297 K and 373 K.

The crystal structure of triclinic $K_2Fe(SO_4)\cdot 2.2H_2O$ at 297 K was determined by use of an automatic four circle X-ray diffractometer in space group P1, a=7.308(1), b=10.816(2), c=6.531(1)Å, α=109.03(1), β=110.50(2), γ=94.53(1)º, V=446.1(2)A^3, Z=2.

The cell dimension at 373 K are; a=7.296(2)A, b = 5.377(2)A, c=6.567(2)A, α=107.99(2), β=110.13(2), γ=94.59(2)º, V=446.1(2)A^3, Z=1. The space group was P-1. This crystal undergoes a phase transition at 364 K.

The phase is transformed to the same triclinic structure, but the space group is different P1-P-1. The structure successfully converged: R=0.025, R_w=0.045 and S=1.94 for the low temperature phase, and R= 0.034, R_w=0.069 and S=2.21 for the high temperature phase.

P06.10.001 MODULATED CRYSTAL STRUCTURE OF $Sr_6Rh_5O_{15}$. C. Schinzer, Institut de Chimie de la Matière Condensée de Bordeaux (I.C.M.C.B.–CNRS UPR 9048), Av. Dr. A. Schweitzer, F-33608 Pessac cedex, France.

The compound $Sr_6Rh_5O_{15}$ has been synthesized by standard solid state techniques starting from $Sr(NO_3)_2$ and $Rh_2O_3 \cdot 5\ H_2O$.

A structural model has been proposed previously by Claridge and zur Loye [1] on the basis of x-ray powder data. The structure is described as a variant of the $Sr_6Co_5O_{15}$ type which is a n = 1 member of the so-called Darriet-Subramanian-phases [2] with general formula $A_{3+3n}A'_nB_{1+3n}O_{9+6n}$ (A = Sr; A', B = Rh). Claridge and zur Loye have been able to refine their product in a superstructure of the ideal $Sr_6Co_5O_{15}$ type doubling the hexagonal lattice parameter a with good reliability.

However, electron microscopy studies of our product indicate an incommensurately modulated structure. The modulation vector was determined on the basis of the ED pattern, which was indexedusing four Miller indices [3]. The modulation is one-dimensional obeying the value

u* = (0 0 0.608).

A subsequent translation of these results into the setup of the unit cell of $Sr_6Co_5O_{15}$ allowed to perform Rietveld refinements of the modulated structure on synchrotron powder patterns using the SIMREF 2.5 software [4].

Possible descriptions of the structure of $Sr_6Rh_5O_{15}$ comprise compositionally or displacively modulated as well as composite models with 3D subcells for the Sr- and the Rh-O networks.

The results of Rietveld refinements and of several chemical substitutions (series Sr_xRhO_3; $Sr_6ARh_4O_{15}$, A = Ca, Mg, Zn) will be presented.

P06.10.002 DEBYE-WALLER FACTORS IN A QUASICRYSTAL. R. Colella, Y. Zhang, J. P. Sutter, S. N. Ehrlich, Purdue University, Dept. of Physics, West Lafayette, IN 47907-1396, U.S.A. and S. W. Kycia, CHESS, Cornell University, Ithaca, NY 14853-8001, U.S.A.

The mean square vibrational amplitude $< U^2 >$ for five reflections located on a two-fold axis of an icosahedral quasicrystal $Al_{71.0}Pd_{20.5}Mn_{8.5}$ have been determined between room temperature (RT) and below 20 K by x-ray diffraction. Their Q-vectors ($Q = 2\sin\theta/\lambda$) range from 1.278 $Å^{-1}$ to 2.556 $Å^{-1}$. For four reflections, the logarithm of the integrated intensity is linear, proportional to temperature, near and below RT, and tends to saturate to a constant value at low temperatures (LT), an effect of the zero point energy. It is assumed that $< U^2 >$ is contributed mostly by low frequency acoustic modes, for which the atoms of Al, Pd and Mn vibrate together. All plots for these four reflections are indeed linear at RT and below, and saturate at LT to values that are different from those predicted by Debye theory. This behaviour is reminiscent of that of layered crystals[1] such as graphite or TaS_2, in which the anomaly could be explained by considering the effect of reduced dimensionality and anisotropy,

none of which can be applied to icosahedral quasicrystals. Furthermore, the Debye temperatures obtained from the linear regions of the four plots are substantially different, for different Q's. The fifth reflection (Q = 2.252 $Å^{-1}$) displays a temperature dependence that does not lead to a single mean square vibrational amplitude. In other words, the logarithm of the integrated intensity is not linear with temperature in the high temperature region (T ≥ 100 K). Since the fifth reflection is very weak, it is possible that a strong negative interference between different atoms is taking place. In this situation it is no longer permissible to talk about a single ``global" Debye-Waller factor, corresponding to a single vibrating mass.

Work is in progress to understand the physical origin of non-Debye behaviour in a quasicrystal.

P06.10.003 A (3+1+1) MISFIT LAYER OXIDE COMPOUND: $Bi_{1.85}Sr_2Co_{1.85}O_{8-\delta}$. D. Grebille, H. Leligny, O. Pérez, A. C. Masset, M. Hervieu and B. Raveau, Lab. CRISMAT (UMR CNRS 6508), ISMRA, 6 Bd du Maréchal Juin, 14050 Caen cedex France.

The system Bi-Sr-Co-O is rich of a lot of modulation phases, closely related to the family of high T_c superconducting oxides. A new compound $Bi_{1.85}Sr_2Co_{1.85}O_{8-\delta}$ was synthetized and present original features. Its structure was refined using X-ray single crystal diffraction data.

The electron and X-ray diffraction patterns clearly show a composite structure with two subsystems of monoclinic symmetry, sharing **a** and **c** cell parameters but with irrationnaly related **b** parameters (**a** = 4.905 Å, $\mathbf{b}_I$ = 5.112 Å, $\mathbf{b}_{II}$ = 2.808 Å,**c** = 29.857 Å, β = 93.45°). Moreover, the first subsystem is also characterized by an intrinsic incommensurate modulation with a wave vector $\mathbf{q}^*_{11}$ = 0.293(2) $\mathbf{a}^*_{11}$ +0.915(2) $\mathbf{a}^*_{13}$ in the common monoclinic plane. Structure refinement was achieved using the 5D superspace formalism (superspace group I2/a (α 0 γ, 0 μ 0) pmm or I2/a (α 0 γ, 1 μ 0) pmm) leading to very satisfactory agreement factor (R_G=0.0405, R^I_0=0.0335, R^I_1=0.0427, R^I_2=0.1090, $R^{I,II}$=0.0319, R^{II}_0=0.0817).

Subsystem I appears to be very similar to the usual modulated [$BiSrO_2$] layers of the so called 2201 type structure with regards to the longitudinal modulated displacements. Subsystem II is consistent with the coexistence in the same crystal of two variants with different centering conditions, built from the stacking of [CoO_2] layers. The interaction between the two subsystems appears to be very weak and could not be measured.

This structure can be compared with equivalent sulphur compounds, but is quite original in oxide systems.

P06.10.004 SURFACE STRUCTURE OF $Sr_2Nb_2O_7$ (010) STUDIED BY X-RAY DIFFRACTION. R.Suetoshi[1], S.Doi[1], I.Takahashi[1], and K.Ohi[2], [1]Advanced Research Center of Science(ARCS), Kwansei Gakuin University, Sanda 669-1337, Japan, [2]School of Science and Engineering, Waseda University, Tokyo 169-0072, Japan

Many dielectric substances are known to possess incommensurate (IC) phases between the disordered (paraelectric) and the ordered (ferroelectric or ferroelastic) phases. Although such an interesting phase transition should be ascribed to some competing interactions, we do not know how a crystal acquires the long-period which often exceeds hundreds Angstrom. A breakthrough, which should be brought by a novel experiment, is surely longing. On the other hand, effects of the bulk IC structures on the surface structures have been scarcely dealt with as yet. We started to investigate the surface structure of IC dielectrics on a microscopic standpoint, since this problem is thought to gives us a key to reveal the origin of the bulk IC phase transitions. In the present study, we investigate the (010) surface of strontium niobate ($Sr_2Nb_2O_7$), which has the IC structure at room temperature. $Sr_2Nb_2O_7$, which is composed of slabs with distorted perovskite type octahedra stacked along the [010] axis, has the strong cleavage parallel to the b-plane. Since the (0k0) CTR (Crystal Truncation Rod) scattering from the cleaved (010) surface was observed clearly, we found that the surface was flat in atomic level. After least-squares procedures, the probability of finding the Sr atom at the top of the surface, which occupies on the right site, is about 50%. This fact leads us to consider that half of the Sr atoms were lost or arranged disorderly when the crystal was cleaved. Moreover, the diffuse scattering emanating from satellite reflections almost perpendicular to the (010) surface such as connecting each satellite was observed. The diffuse scattering had been observed by electron microscopy and regarded as the effect of the irregularity of modulation wave due to phase shift in some perovskite-type slabs[1]. Temperature dependence of these scatterings is now in progress, we would like to present the quantitative evaluation of the IC structure at the surface and in bulk.

P06.10.005 THE LARGEST RATIONAL APPROXIMANT TO THE DECAGONAL PHASE IN THE SYSTEM Al-Co-Ni Katja Lemster[1], Michael E. Estermann[1], Walter Steurer[1] & Benjamin Grushko[2] [1]Laboratory of Crystallography, Swiss Federal Institute of Technology, CH-8092 Zurich, Switzerland [2]IFF, Research Center Julich, D-52425 Julich, Germany

A novel decagonal approximant with the largest unit cell of all known intermetallic compounds was found in the system Al-Co-Ni. This approximant is a link of the transition between quasicrystal and crystal. The structure of the approximant with nominal composition $Al_{71}Co_{14.5}Ni_{14.5}$ was solved with single-crystal X-ray diffraction techniques.

Although the unit cell shows almost orthorhombic symmetry, with unit cell parameters of a = 8.17(5)Å, b = 75.05(5)Å, c = 78.90(5)Å, α = 90.02(5)°, β = 89.99(5)°, γ = 89.98(5) °, the diffraction symmetry is monoclinic with space group $P2_1/n$ (unique axis **c**).

The intensity distribution of Bragg peaks shows strong tenfold pseudosymmetry. The monoclinic axis **c** is perpendicular and not parallel to the pseudosymmetric tenfold direction, which runs along **a**. A columnar cluster (*monopteros*) with an average fivefold symmetry is found as a structural building unit [1].

The structure was solved with “image seeking” Patterson methods [2].

In our contribution we want to show the process from the data collection to the refinement of the structural model. With respect to the size of the unit cell, the pseudosymmetry, and the numerous diffraction data we shall demonstrate useful methods and techniques for this kind of problem.

P06.10.006 APERIODIC CRYSTAL STRUCTURE AND CONDUCTIVITY OF DENTAL ENAMELS AND A SPECIAL PORCELAIN ENAMEL. Nguyen Van Tri, Institute of Engineering Physics, Hanoi University of Technology, Hanoi, Vietnam.

From the experimental results on the temperature variation of electrical resistivity of dental enamels and of a special porcelain

enamel, a special conduction effect of these enamel films was revealed : At normal room temperatures these enamels are highly insulative and with rising temperature they experience a very strong increase in conductivity. Especially, once the temperature falls to below the room one these enamels transform suddenly into good conductors. This particular property of the enamels is similar to that for the typical stable quasicrystal material recently discovered, basically made of seventy atomic percent of Aluminium and of transition metals[1].

On the other hand, the careful ESR studies on these non-crystalline enamel films suggest that the films show a very outstanding angular dependence effect being exactly the same as of a single crystal sample with a typical highfold axial symmetry. The symmetry axis is perpendicular to the enamel surface. The ESR results also suggest detailedly this quasicrystal effect is closely connected with the fivefold symmetry combination clusters distributed in the enamel film, whose planes are parallel to enamel surface. Every this fivefold structure unit is combined by fivefold (2F-2A) rhombs of four spin centers super-exchange-interacting and creating two diagonal spin couple pairs : the pair A (Antiferromagnetic) on the long diagonal with a high population density of the singlet electron state at lower temperatures and the pair F (Ferromagnetic) on the short diagonal with a high population density of the singlet electron state at higher temperatures. Evidently, the particular properties of the enamel are in close internal connection with this electronic dynamics of its quasicrystal structure.

Wonderly, the fivefold combination clusters in the mentioned enamels are also observed directly to the first time by the respective AFM recordings.

P06.10.007 MAXIMUM ENTROPY ATOMIC SURFACES RECONSTRUCTION: THE *nD* STRUCTU- RE OF DECAGONAL AlOsPd. A.Cervellino, T.Haibach and W.Steurer, Laboratorium für Kristallographie, ETHZ, CH-8092 Zürich, Switzerland.

The power of the Maximum Entropy method to reconstruct the electron density[1] has been effectively combined with the simplicity of the *nD* embedding model[2] to describe a decagonal phase[3]. AlOsPd is the largest existing decagonal ($P10_5/mmc$) quasicrystal. Its z-period is 16.750(3)Å, comprising eight layers. The electron density peaks in the Maximum Entropy-reconstructed asymmetric unit have first been localized in very good agreement ($\sim 10^{-2}$Å) with the corresponding βZ module-inferred coordinates. The electron density peaks have then been integrated and lifted on the corresponding atomic surfaces. Two important indications are hence obtained: the chemical partition of the atomic surfaces and the estimate of the z-displacements from the average layers located at the eighths of the z-period.

P06.10.008 TWO FLUORITE-RELATED PHASES AND THEIR MODULATED STRUCTURES IN Bi_2O_3-Ta_2O_5 OXIDES. R. Miida and T. Saito, SUT, Suwa College, Toyohira 5000-1, Chino, Nagano 391-0292, Japan, and M. Tanaka, RISM, Tohoku University, Sendai 980-8577, Japan

In the oxides $(Bi_2O_3)_{1-x}(Ta_2O_5)_x$, a fluorite-related phase has been reported to exist in the compositional range from x=0.21 to 0.25 [1]. In addition to that, another fluorite-related phase was recently found at compositions between x=0.05 and 0.08, and these two phases were called as FI for $0.21<x<0.25$ and FII for $0.05<x<0.08$ [2]. In the present study, we examined these phases by means of electron diffraction and microscopy.

The diffraction pattern of FI showed satellite spots at $n\boldsymbol{q}\boldsymbol{G}_{111}$ (n=1, 2, . . ,) and equivalent positions with them together with the fundamental Bragg spots, where $\boldsymbol{G}_{111}$ denotes the 111 reciprocal lattice vector. The value of q varies from 0.373 to 0.380 with increasing x in the FI zone. The diffraction pattern is quite similar to that of Bi_2O_3-Nb_2O_5 reported already. [3].

The diffraction pattern of FII showed a pair of diffuse spots at $(\frac{1}{2}\pm\pm)\boldsymbol{G}_{111}$ and equivalent positions with them, where q varies from 0.125 to 0.135 with increasing x in the uniform zone. The pair of diffuse spots can be regarded as the reflections split from the $\frac{1}{2}\frac{1}{2}\frac{1}{2}$ superlattice reflection due to the introduction of pseudo-periodic anti-phase boundaries (APBs) parallel to the (111) planes. The structural model for q=0.125 contains APBs at intervals of $4d_{(111)}$ ($d_{(111)}$=spacing of (111) planes) in the displacement type ordered structure with the period of $2d_{(111)}$. The introduction of APBs modifies the sequence of local periods in the [111] direction as . 123212321232 in $d_{(111)}$ unit. A sinusoidal modulation with the period of $8d_{(111)}$ is imposed on the atomic displacements. The model roughly reproduces the intensity distribution in the electron diffraction pattern.

P06.10.009 PARTICLE SIZE DISTRIBUTIONS AND STRUCTURE INVESTIGATIONS IN SYSTEMS OF COLLAPSED GELS. E.V.Shtykova, D.I.Svergun and A.T.Dembo, Institute of Crystallography, Russian Academy of Sciences, Leninsky pr., 59, 117333 Moscow, Russia, L.M.Bronstein and P.M.Veletsky, Nesmeyanov Institute of Organoelement Compounds, Rassian Academy of Sciences, Vavilov st., 28, 117813 Moscow, Russia and A.R.Khokhlov, Physical Department, Moscow State University, Russia.

Small-angle X-ray scattering is used to study collapsed gel structures and size distributions of metal nanoparticles embedded in polyelectrolyte hydrogels with oppositely charged surfactants. A procedure is proposed to subtract matrix scattering and to extract pure scattering due to the nanoparticles allowing to evaluate their size distribution functions by means of a regularization technique.The main results of the study are the following: metall compounds in the gels form small clusters transforming into pure metal particles after reduction;collapsed gel/surfactant complexes stabilize the nanoparticles produced;the ordering in the collapsed gels structure is preserved upon reduction if the gel charge coincides with that of the metal ions;fast reduction yields much smaller particles than the slow one;metal ion charge and geometry influence considerably the particle size distributions;the use of the collapsed gels permits to produce metal nanoparticles with desired size distributions.The obtained results illustrate the potential of the small-angle X-ray scattering method allowing a systematic selection of the materials and reducing agents for the preparation of new compounds with desired properties.

P06.10.010 RESIDUAL STRESS MEASUREMENTS IN MICRON REGIONS BY MEANS OF THE KOSSEL TECHNIQUE. J. Brechbühl, J. Bauch, H.-J. Ullrich, Institute of Materials Science, Dresden University of Technology, 01062 Dresden, Germany.

Most of the conventional X-ray diffraction methods, e. g. the $\sin^2\Psi$ - method, are intended to obtain residual stresses from the surface of multicrystalline materials. Thus, by the procedure of measurement, these methods only provide average stress values of

many grains in areas of several square millimeters. Local deviations from the measured mean values of the stress components, especially within a single grain, cannot be identified. Hence, for the last twenty years new methods for diffractometer measurements in single grains have been developed and applied successfully. But even in the case of coarse-grained materials, when the diameter of the primary X-ray beam may be enlarged to hit still a single crystal, the measuring time is several hours up to several days. Therefore, we have been looking for nonconventional methods to shorten the high measuring time as well as to improve the local resolution.

In the submitted contribution, a new method for fast measurements of residual stresses in micron regions based on the Kossel diffraction is represented. Recently, we performed the first measurements of residual stresses by using synchrotron excited Kossel diffraction (at the HASYLAB, Hamburg). Our new findings as well as the principle of the determination procedure for obtaining residual stresses from Kossel lines are presented. The Kossel technique is a very suitable method for fast measurements (a few seconds / minutes) of local residual stresses in micron regions (spot diameter of the beam: electron excitation: 1-10 μm, excitation by synchrotron radiation: 10-200 μm). Because of the high lateral resolution even residual stresses of third order (inhomogeneities of the stress state within a grain) can be proved and calculated. It is shown that both the measuring time and the measuring errors could be minimized extremely because of the simultaneous registration of differently orientated net planes in one Kossel pattern. There is no necessity to tilt and twist sample and detector during the measurement.

P06.10.011 X-RAY POWDER DIFFRACTION MEASUREMENTS OF THE RESIDUAL STRAINS IN $MgAl_2O_4$-ZrO_2 CERAMIC COMPOSITES. O.Masson, ESRF, BP 220, F-38043 Grenoble Cedex, France, R.Guinebretiere, Z.Oudjedi and A.Dauger, SPCTS, 47 avenue A. Thomas, 87065 Limoges Cedex, France.

The introduction of tetragonal ZrO_2 particles into a ceramic matrix can result in significant increases of fracture toughness and strength. This reinforcement largely depends on the strain field in the matrix and particles.

Because neutrons have a penetration power much higher than X-rays, neutron diffraction is generally preferred for the measurement of bulk residual strains[1]. However, X-ray diffraction is well suited to measure the small line broadening and peak shift induced by inclusions and thus enable valuable strain information to be obtained on the near-surface of the sample.

We present some results concerning X-ray powder diffraction measurements of the residual strains in $MgAl_2O_4$-ZrO_2 composites containing 3 and 12 vol% ZrO_2. The diffraction data were analysed by pattern decomposition. The average lattice strains were determined thanks to the diffraction peak shifts observed in several crystallographic directions. The analysis shows that for all samples the zirconia particles are in tension and the matrix is in compression. Moreover, these lattice strains vary with inclusion content and are anisotropic within the ZrO_2 particles.

Line broadening analysis by the Voigt function method[2] was used to determine the local mean-squared strain. For both phases, microstrains were found to increase with the inclusion content. Finally, the W.A. method[3] was applied to obtain more information on the strain field distribution. Fourier coefficients were beforehand computed by using a regularisation method in order to avoid spurious oscillations caused by the instrumental broadening correction. We then show that the strain field gradient induced by inclusions within the matrix is small.

P06.10.012 STRAIN IMAGING BY NEUTRON TRANSMISSION. P. Withers [1], L. Edwards [2], M. Johnson, M. Daymond [3], A. Steuwer [4], [1] Manchester Materials Science Centre, UMIST, Grosvenor Street, Manchester M1 7HS, [2] Materials Discipline, The Open University, Walton Hall, Milton Keynes, [3] ISIS Facility, Rutherford Appleton Laboratory, Chilton, Didcot, Oxon OX11 0QX, [4] Department of Materials Science & Metallurgy, University of Cambridge, Pembroke Street, Cambridge CB2 3QZ

In the time-of-flight method, the intensity of neutrons transmitted through a polycrystalline sample exhibits sudden, well-defined increases when the neutron wavelength exceeds the Bragg condition for coherent scattering by lattice planes. The shape and position of these edges reflect the crystalline state of the material, and information about residual stress, texture and phases present in the material can be extracted from the spectrum. The transmission method has two key advantages over conventional neutron diffraction. The use of pixellated 1D or 2D detectors enables simultaneous spatial imaging of stress fields and, at the same time, allows for the determination of the unstressed lattice spacing by taking a set of images at different sample inclinations. In this paper we present analysis and preliminary results to show how neutron transmission can be used for accurate strain measurements in materials, based on single-edge and Rietveld-type multiple-edge refinement.

P07.10.001 A SYNCHROTRON DIFFRACTION STUDY OF AMORPHOUS $BaSi_2O_5$. H. Schlenz, R. Grabinski and A. Kirfel, Mineralogisch-Petrologisches Institut, Universität Bonn, D-53115 Bonn, Germany, schlenz@uni-bonn.de

The structure of a synthetic Ba-silicate glass of composition $BaSi_2O_5$ has been studied by high energy synchrotron diffraction (150 keV) at the wiggler synchrotron beam-line BW5 at HASYLAB/DESY (Germany), and at three different energies (35.5, 36.8 and 37.3 keV) near the Ba K-absorption edge, at the synchrotron beam-line F1 (HASYLAB/DESY). Hard X-rays (150 keV) were used, because a higher resolution in direct space desired for disordered materials can be achieved, and the required corrections are smaller, particularly that for absorption. Due to smaller scattering angles, even the polarization correction is almost negligible [1]. All experiments were carried out in Debye-Scherrer geometry illuminating a capillary with 3 mm and 1mm diameter respectively (Sample holder: pure silica glass capillary, 0.01mm wall thickness). At 150 keV the sample was placed into a vacuum chamber (P = 0.001 mbar), in order to reduce air scattering at low values of Q (= $4\pi\sin\Theta/\lambda$). The experiments at lower energies were performed at normal conditions. Data were recorded in a range of Q between 0.8 and 38.7 $Å^{-1}$. In order to employ experimental anomalous dispersion correction terms, f ' (E) and f " (E), in the course of data processing, the Ba K-edge was studied by EXAFS-scans. Effective absorption coefficients μ (E) were determined from sample transmission measurements at all energies. The data were evaluated conventionally, and the differential anomalous scattering method (DAS) was applied [2], in order to obtain interatomic distances of next nearest neighbours, i.e. the Ba-Ba distances from the partial Ba-Ba structure factor.

P07.10.002 STRUCTURE AND PHASE TRANSITION IN Ti-Ni ALLOYS DUE TO CRYSTALLIZATION AMORPHOUS ALLOYS. I. Doonichev and A. Kosilov, Department of Physical of Metals, Voronezh State Technical University, 394026 Voronezh, Russia, Yu. Barmin and S. Lebedinsky, Department of Solid State Phisics, Voronezh State Technical University, 394026 Voronezh, Russia.

Amorphous alloys $Ti_{1-x}Ni_x$ ($0{,}16 \le x \le 0{,}74$) were prepared by sputter-deposition as substrateless films 10-15 μm thickness. Compositions of alloys were measured by electrone probe microanalysis. Investigations of alloys structure in initial state and after annealing were study by X-ray diffraction. The survey was conducted in the Bragg-Brentano geometry with application of a graphite monochromator in a diffracted beam and scintillation counter detector arranged to eliminate $\lambda/2$ contributions.

Amorphous alloys were annealed at two various temperature. The degree of vacuum prior to starting annealing was nearly $1 \cdot 10^{-6}$ Pa. The amorphous specimens for fist annealing were heated few higher the crystallization temperature for 5 min. Ti-Ni alloys for second annealing were heated for 1 h at 1000 K. Structure in initial state and after annealing were study in this work The short-range order of the crystallite phases is analysed in connection with the structures of amorphous alloys.

P07.10.003 ATOMIC STRUCTURE AND PHASE TRANSFORMATION OF AMORPHOUS ALLOYS $Re_{100-X}Hf_X$ (X=4 - 91 AT.%). E.V. Lebedinskaya, S.A. Lebedinskiy and Yu.V. Barmin, Dept. of Solid State Physics, Voronezh State Technical University, 394026 Voronezh, Russia.

Amorphous alloys $Re_{100-x}Hf_x$ (x = 4 – 91 at. %) were prepared by vapour quenching (high rate sputter deposition) of composite target as a substrateless foils 10 - 15 μm. The composition of alloys was determined by electron-probe microanalysis method with 0,5 at. % accuracy.

The atomic structure of initial structure and phase transformation of amorphous alloys Re-Hf during to heating was studied by X-ray diffraction. As a result of X-ray experiment using $Mo_{k\alpha}$ radiation calculations the radial distribution functions and the structure factors for all amorphous alloys in all concentration range $4 \le x \le 91$ were obtained.

In order to study the phase transformation during heating the special treatment was carried out with heating rate 10 K/min.

The short range order parameters (interatomic distances R_i and coordination number Z_1) were determined. The values of R_i/R_1 and Z_1 are constant in all compositional range. Crystallization only to α-Hf, Laves phase, Re_2Hf, and Re but not to equilibrium σ- or χ-phases was established.

P07.10.004 XRD, XANES AND EXAFS STUDY OF NiO XEROGELS. H. Fischer and A.F. Craievich, Instituto de Física, CP 66318,05315-970, USP, São Paulo, SP, Brasil and P.K. Sharma, Materials Center, SUNY, Binghamton, USA.

Porous *NiO*-based xerogels were prepared using the sol-gel procedure. The precursor sol is composed of nickel chloride and different amount of water (1 and 9 mol), in the presence of 0.1 mol of acetic acid, dissolved in butanol. The liquid solutions were refluxed and the resulting sols dried and held during one hour at temperatures ranging from 150 up to 900°C. The structure of *NiO* xerogels, treated at different temperatures, was studied by X-ray diffraction (XRD), XANES and EXAFS techniques [1]. XRD spectra corresponding to low temperatures (150 to 300°C) exhibit diffraction lines of $NiCl_2\ xH_2O$ (x=2, 4 and 6) crystals. For samples treated at higher temperatures, the intensity of these peaks progressively decreases and others corresponding to the cubic *NiO* phase appear. XANES spectra of low temperature xerogels, corresponding to *Ni* atoms surrounded by *Cl*, smoothly approach, as temperature grows, that of *NiO* standard. The same type of transformation is apparent in the variation of the area of the *Ni-Ni* peak of EXAFS results. We propose that this variation is produced by the progressive formation of crystalline *NiO* volume domains, in which *Ni-Ni* distances are equivalent to those of the *NiO* standard. In order to determine the volume fraction of transformed *NiO* phase, *c(T)*, XANES spectra corresponding to intermediate temperatures were modeled as linear combinations of the reference spectra of the two standards ($NiCl_2$ and *NiO*). *c(T)* was independently determined using EXAFS results. A sigmoidal function was fitted to the experimental values *c(T)* yielding an average transformation temperature T_t=476°C and a transformation range width ΔT=52°C for 1 mol H_2O. When water content is increased, the phase transformation shifts slightly toward lower temperatures and the extent of the transformation range is reduced (T_t=460°C and ΔT=42°C for 9 mol H_2O).

XANES and EXAFS experiments were performed at the National Synchrotron Light Laboratory, Campinas, Brazil.

P07.10.005 SHORT RANGE ORDER AND PHASE TRANSFORMATIONS OF Re-Si AMORPHOUS ALLOYS. I.V.Babkina, Yu.V.Barmin, V.G.Samoilov Department of Solid State Physics, Voronezh State Technical University, Moskovskii Prospekt 14, 394026 Voronezh, Russia.

The atomic structure of $Re_{100-x}Si_x$ (x=0, 4, 11, 20, 31, 47, 54, 70, 82, 88, 100) amorphous alloys (AA) was studied by X-ray diffraction. Amorphous alloys were prepared by high-rate sputter deposition. The compositional range formation of the amorphous state in Re-Si system (10-100 at.% Si) was determined.

In as-quenched alloys two amorphous phase were observed: the AI-phase - 10-90 at.% Si and the AII-phase - 45-100 at.% Si, especially that in the composition range 45-90 at.% Si is the coexistence of two phase AI and AII. The values of interatomic distance R_1=2,63-2,71 A and total coordination number Z_1=9,6-9,9 have been determined for the one-phase region.

The interrelation between the topological short-range order parameters, the thermal stability (crystallization temperature T_x) and the structure of crystallized metastable phases (MS) of Re-Si AA have been investigated. After the crystallization the basic phases are Re_5Si_3 and $ReSi_2$, with the extended of the compound $ReSi_2$ existence area, while the ReSi-phase is not identified among the crystallization products. The linear dependence of T_x upon the composition is found for AA crystallized into Re_5Si_3 and $ReSi_2$ compounds that is conditioned by the similarity of their topological short range order structure. The decreasing of T_x with the alloy composition changing from the stoichiometry of Re_5Si_3 and $ReSi_2$ is the cause of the changing of the composition short range order of these compounds and corresponding AA.

As a conclusion - the short-range order of AI-phase and coordination polyhedrones of Re_5Si_3 and $ReSi_2$ compounds is similar. The structure of AII-phase is the same as a-Si.

P07.10.006 NEUTRON POWDER DIFFRACTION STUDIES OF ETTRINGITE. R. Pisula, Department of Crystallography, Birkbeck College, Malet Street, London WC1E 7HX.

Ettringite ($Ca_6[Al(OH)_6]_2.(SO_4)_3.26H_2O$) is an important product in the hydration of Portland cement, where its early formation is critical for set regulation and rheology. The subsequent 'to and fro' conversion of ettringite and calcium monosulphate aluminate ($[Ca_2Al(OH)_6.xH_2O]$, a solid solution series), that occurs in older cements is critical for the long term strength of the cement matrix.

In this study we are investigating the effect of temperature and crystallite modification on this transformation reaction. Our

interest is to relate the kinetics of this conversion to the structure and composition of the mono- sulphate phases. We have also prepared high-purity crystalline ettringite in a deuterated form for a complementary neutron diffraction study to monitor water content during the transformation. The data analysis shows the decomposition process clearly and the emergence and subsequent disappearance of the important fragment mono-sulphate. Based on these results we discuss the nature of the transformation, and the water content of each phase during decomposition.

P07.10.007 SYNCHROTRON E.D. DIFFRACTION TOMOGRAPHY STUDIES ON PORTLAND CEMENT TREATED WITH SUPERCRITICAL CO_2. Shane Morgan, Birkbeck College.

Cement studies continue to yield new processes of modifying cement to improve and diversify its properties for various applications. A recent novel area of research is into a way of hardening Ordinary Portland Cement (OPC), using supercritical carbon dioxide ($SCCO_2$). Strengthening of cement does occur naturally due to carbonation, where calcium compounds in the cement react with carbon dioxide in the atmosphere to form calcium carbonate (Limestone)and water, over long periods of time. We can mimic the conditions of exposure to carbon dioxide, but over very short periods of time by bathing the OPC in $SCCO_2$. This diffuses easily while under pressure through the cement altering the cement chemistry as it progresses. In this work we are interested in mapping the progress of this cement/$SCCO_2$ interaction using Synchrotron Energy Dispersive Diffraction (SEDD). We have produced cement samples with varying levels of carbonation and water content and observed these using Energy-dispersive x-ray diffraction tomography at Daresbury Laboratories on station 16.4. We have mapped the composition of crystalline material in the cement, along a path from interior to exterior of the sample. Analysis shows clearly the changes in the cement chemistry i.e the formation of calcium carbonate and disappearance calcium hydroxide as we move into the sample and the appearance of unexpected phases. Using SEDD we have shown non-destructively the main alterations that give improved strengths to the cements and correlated these to various $SCCO_2$ treatments.

P07.10.008 COMPOSITION EFFECTS ON THE CRYSTALLININTY OF BERYLLIUM-RICH COATINGS. A. Jankowski, Chemistry and Materials Science, Lawrence Livermore National Laboratory, Livermore, California, USA

The material properties of sputter deposited coatings are sensitive to the growth morphology and microstructure of the deposit. For example, the application of an applied bias to the substrate can densify the columnar microstructure of a crystalline coating through ion bombardment thereby minimizing porosity and increasing the mechanical strength of the coating. We are developing a process to sputter deposit Be-rich, thick coatings that must be homogeneous, isotropic, mechanically strong, smooth and serve as a membrane across which gas permeation is controllable. The refinement of grain size to the nanoscale is preferable for each of these attributes.

It is widely known from prior studies of evaporation and sputter deposition that the grain size of nominally pure beryllium, that is beryllium with greater than 99.8 atomic percent purity, can be dramatically refined through the incorporation of specific metal impurities like iron. Additionally, the use of boron doping may serve as a potential glassy phase former in the composition range greater than at the depressed eutectic seen in the binary alloy phase diagram. We report on the changes in crystallinity and growth morphology found in these Be-rich coatings. The effects of dopant additions are characterized with electron diffraction and microscopies.

This work was performed under the auspices of the US Department of Energy by Lawrence Livermore National Laboratory under Contract No. W-7405-ENG-48.

P07.10.009 OXIDE PHASES IN SYSTEMS xR_2O_3-$(1-x)Fe_2O_3$, R=RARE EARTH. S. Popovic, Physics Department, Faculty of Science, POB. 162; and M. Ristic and S. Music, Rudjer Boskovic Institute, POB. 1016; 10001 Zagreb, Croatia

Rare earth ferrites find wide-scope applications in telecommunication and electronic devices, due to their specific physical properties. For that reason a systematic study of the influence of the preparation procedure on the formation of particular oxides and their properties has been undertaken. The main characterization techniques have been XRD, FT-IR, Mössbauer and Raman spectroscopy.

R=Eu,Gd: Samples were prepared by chemical coprecipitation of corresponding hydroxides. For $x \approx 0.4$ and 0.5 the garnet-type ferrite and orthoferrite, respectively, were dominant in samples heated at 900°C, while samples heated up to 600°C were of poor crystallinity. There was no evidence for formation of solid solutions, even at ends of the concentration range. The distribution of observed oxides was determined as a function of x. For samples prepared by ceramic sintering a temperature of 1200°C was necessary for formation of the garnet-type ferrite and orthoferrite at $x = 3/8$ and $x = 0.5$, respectively.

R=Nd: In samples prepared by chemical coprecipitation and heated up to 900°C the highest fraction of orthoferrite was obtained for $x = 0.5$.

R=Sm: Samples were prepared by solid-state reaction. For x=0.5 orthoferrite was detected as one of oxide phases after heating up to 800°C, and as a single phase above 1000°C. For $x = 3/8$ garnet-type ferrite was a single phase in samples heated at 1300°C.

R=Er: Samples were prepared by chemical coprecipitation. For $x = 3/8$ samples heated up to 650°C were amorphous, heated up to 800°C showed the garnet-type ferrite and orthoferrite, while heated up to 1300°C contained the garnet-type ferrite as a single phase.The present study shows strong relationships between the preparation procedure, nature of metal cations and structural and chemical properties of the formed oxides.

P07.10.010 STRUCTURAL STUDY OF BORON CARBIDE MODIFIED BY INDUCTION PLASMA TREATMENT. T. Tanaka, Technical Research Laboratories, Nisshin Flour Milling Co., Ltd., 5-3-1, Tsurugaoka, Oi, Saitama 356-8511, Japan, and X. Fan and T. Ishigaki, National Institute for Research in Inorganic Materials, 1-1, Namiki, Tsukuba, Ibaraki 305-0044, Japan.

Transmission electron microscopic and powder X-ray diffraction studies revealed that the structural modification in boron carbide was induced by an in-flight R.F. induction plasma treatment, which is characterized by its high enthalpy and the presence of chemically active species. Boron carbide (B_xC), which has a rhombohedral cell with space group $R\bar{3}m$, was known one of non-metallic hard materials and expected to the coating material in spray plasma coating process. In this study, B_xC powders were modified by the Ar-H_2, Ar-N_2 and Ar-H_2-NH_3 R.F. induction plasma treatment, and the changes of their stoichiometry and crystal structure were investigated by transmission electron microscopic and powder X-ray diffraction technique. In transmission electron microscopic study, a lot of crystallites with stacking faults were observed in the thinned cross section of Ar-H_2 treated B_xC particles. It was considered that these particles were melted completely during plasma treatment. On the other hand, the formation of boron, which has a doubled a length in

comparison with B_xC unit cell, and remarkable change in profile intensity of B_xC was observed in powder X-ray diffraction study of each plasma-treated powder. The Rietveld analysis revealed that the unit cell volume of each plasma-treated B_xC increased with the increases in the occupancy of 1*b* site (0,0,1/2) of space group $R\bar{3}m$. In addition, the unit cell volumes of Ar-N_2 or Ar-H_2-NH_3 plasma-treated B_xC were slightly bigger than those of Ar-H_2 treated one. It was suggested the oxygen or nitrogen atoms took the place of boron atom at 1*b* site through the plasma treatment, considering the atomic radii of each atom. The change of chemical composition in plasma-treated boron carbide agreed with the above results of Rietveld analysis.

P07.10.011 HIGH TEMPERATURE NEUTRON STRUCTURE ANALYSIS OF 3:2 MULLITE. G.Brunauer, H. Boysen and F. Frey [1], T. Hansen [2], W. Kriven [3], [1] Institut für Kristallographie, LMU, 80333 München, Germany, [2] ILL, 38042 Grenoble, France, [3] Department of Material Science, University of Illinois, Urbana, USA

Hydrothermally grown powder of mullite with stoichiometry Al4.5Si1.5O9.75 was prepared by Kriven et al. [1] using the hotpressing method. By neutron diffraction, the temperature behaviour of the mullite sample was examined up to 1923 K. The measurements have been performed at the neutron diffractometers MAN-I (FRM Garching) and D2B (ILL), and have been evaluated with the Rietveld programs FullProf and RTB. During the first heating cycle an anomaly occured including an irreversible change of the expansion coefficient and a change of the sample colour at about 1400 K. This is correlated with a decrease of the occupation of the so called O(3) oxygen site and an increase of the occupation of the so called O(*) site.

First results of the structure refinement are: The atomic displacement parameters show larger values along z, the direction of the tetrahedral and octahedral chains in the structure of mullite, as compared to the directions of x or y. In addition, discontinuities of the lattice expansion could be observed in the temperature regimes between 800 and 1000 K, and 1700 and 1900 K, which might be of importance for applications of mullite based ceramics.

This work is supplied by funds of the DFG under FR747/15-1.

[1] W. M. Kriven et al., J. Eur. Ceramic Soc. (in press)

P07.10.012 THE REAL STRUCTURE OF γ-ALUMINA. D.O.Klenov, G.N.Kryukova, S.V.Tsybulya, Boreskov Institute of Catalysis, Novosibirsk, pr. Lavrentieva 5, Russia

Using simulation of high resolution electron microscopic images and X-ray powder diffraction patterns the crystal structure of γ-Al_2O_3 prepared by thermal decomposition of boehmite and pseudoboehmite at different temperatures has been refined. It was found that difference between two forms is caused by the peculiarities of vacancy distribution over cation sublattice in the structure: samples of γ-Al_2O_3 synthesized from pseudoboehmite are characterized by statistical distribution of vacancies over cation positions whereas in the samples of boehmite series vacancies are concentrated on the defect planes formed by the shift along (110) and (111) that leads to the appearance of the specific closed pseudohexagonal loops.

The relationship between the atomic arrangement and microstructure of γ-Al_2O_3 has been established. In the samples of pseudoboehmite series the cubic spinel structure preserves in the volume of isolated micrograin of 2-3nm in size from those the big (over 100 nm) polycrystalline aggregates are formed. In the samples of boehmite series the structural coherence is still the same in the volume of every isolated particles being in the form of thin monocrystalline platelet of 100 nm in size, but symmetry lowering of the unit cell to tetragonal one is observed. This tetragonal cell is oriented in a definite way with respect to the plane of defects.

This work was made possible by Grant N97-03-33497 from the RFBR

P07.10.013 THE "IN SITU" INVESTIGATION OF THE NIWO4 SYNTHETHIS BY SR-DIFFRACTION AND XAFS. M.R.Sharafutdinov, B.P.Tolochko, N.Z.Lyakhov [1], S.G.Nikitenko [2], [1] Institute of Solid State Chemistry, Novosibirsk, 630128, Russia, [2] Institute of Catalysis, Novosibirsk, 630090, Russia .

The "in situ" information about NiWO4 solid state synthesis was received by synchrotron radiation time resolved diffraction and XAFS methods. At initial stage of the reaction, NiWO4 was formed with deformed structure, which is different from equilibrium one (lattice parameter is greater, structure is nonstoichiometric). During the reaction the structure of already formed NiWO4 changed. It's possible to suggest, that mechanisms of nucleation of NiWO4 are different for initial and following stages of reaction. At initial stage there are formation of nucleus directly on the NiO and WO3 interfaces, then appears particles, contacting with product and one of the components. Thus, the properties of nucleus is different for different time. The nucleus of different size were formed at different temperatures (310 A at 720 C, 280 A at 680). During the reaction the particles size were growing by exponential low , from 310 A to 530 at 720 C (for ~1600 s) , from 280 A to 400 A at 640 C (for ~5000 s). Integral intensity of the NiWO4 peaks growth described by Avrami-Erofeev model at the initial stage of reaction. After formation of the product layer (alpha > 0.2) kinetics were described by Gistling-Brounstein model. At the temperature about 700 C the constant (k) of reaction was the same for all time of reaction, whereas at 640 one was changed about alpha ~0.5. Considering that at 720 C lattice parameter of WO3 is constant and decrease by 0.1 % at 640 we can suggest that formation of solid solution (NiO)WO3 take a place.

P07.10.014 CRYSTALLOGRAPHIC STUDIES OF NEW PHASES IN THE LA2O3-LI2O-TIO2 SYSTEM. C.A. Kirk, A.R. West, J.M.S. Skakle and S.M. Blake, Department of Chemistry, University of Aberdeen, Meston Walk, Old Aberdeen, AB24 3UE

A study of the compound formation and crystal structure in the system La_2O_3-Li_2O-TiO_2 has shown the existence of five phases, two of which are new. The crystal structure of three of these phases, (B $La_{32}Li_{20}Ti_4O_{66}$, C $La_{14}Li_{20}Ti_3O_{37}$ and D $Li_{0.333}LaTi_{0.667}O_3$) have been studied using a combination of XRD, ND and SAED. Phase B is cubic with a = 12.2163Å and space group Im-3m. Phase C is tetragonal with a = 13.24Å and c = 7.46Å and space group P4/mbm. Phase D is perovskite related and tetragonal with a = 7.87 and c = 7.86 and space group P4/nbm.

P07.10.015 THEORY OF THE CERAMIC FORMATION UNDER THE PRESSURE. A.Yu.Gufan and E.N.Klimova , Applied Mathematical Department, Rostov State University, 5 Zorge st., 344090 Rostov on Don, Russia, and S.O.Kramarov Rostov State Pedagojical University, 33 B.Sadovaya st., 344082 Rostov on Don, Russia.

The process of the ceramic formation under the pressure we have roughly divided on three stages. At the first stage a covities between the grains disappear, defining the compressibility of almost powder specimens. Hardness intergrain contacts restrict the total changing of the volume at the duration of this stage. The second stage is characterized by the grain deformation and

disappearing of interfaces between the grains. The hardness of material becomes almost the hardness of grains. The third stage is characterized by the rising cracks inside of the grain, skeleton suffers distraction and some part of specimen becomes powder as initial one. These stages may be imaged as a mesoscopic first order phase transitions between the phases of materials. The simplest model of this transformations may be characterized by the density of potential energy $w = w/v = (1-c)(k_1 z_1^2)/2 + c(k_2(z_2 - z_0)/2 + w) - pl$ (1) . Where v- samples volume, p-pressure acting on ceramic pill, $l=cz_2 + (1-c)z_1$ – total deformation of the pill, c- is concentration of prepared ceramic, k_1 and k_2 are rigidities of the first and the second stage of ceramic formation which may be defined by dilatometrir measurements, z_1 and z_2 are the corresponding changing of pills height. The theory predicts the critical pressure $p_0 = k_1 k_2 z_0 / (k_2 - k_1)$, defining the interval of the second stage of ceramic formations $p_1<p<p_2$, where $p_{2,1} = p_0[1 +-(1-w_0/w_c)^{1/2}]$ and $w_c = k_1 k_2 z_0^2/2(k_2-k_1)$, p_2 define in the beginning of cracks growing.The relation between the total deformation and the volume sprouting by skeleton of rigid intergrain contacts $[(1-c_1)/v]$ and p_1 is defined by equation: $c_1 = (1-p_1/k_1) / [(p_1/k_2 - p_1/k_1) + z_0]$. The volume of cracked part of ceramic specimen $[(1-c_2)/v]$ is defined by equation $c_2=(1-p_2/k_2) / [(p_2/k_2 - p_2/k_1) + z_0]$. The temperature influence on the ceramic formation in the framework of model (1) will be carefully presented in poster. We are thankful to RFBR for financial support.

P07.10.016 PHASE TRANSITIONS ON THE SCALE OF GRAINS IN THE COURSE OF HARD PILLS MOULDING. V.M.Il'in Rostov Devision Academy of Service, 125 Varfolomeev str. 344018 Rostov ob Don, Russia and A.Yu.Gufan Appl.Math.Department of Rostov State Univ. 5Zorge st., 344090, Rostov on Don, Russia.

Dependence of the powder pills height versus, pressure in a course of solid pills preparation at low temperature displays two jumps corresponding to physical nature of compressibility substitutions. At the beginning, the samples are friable with the vacant holes between the grains. These states rigidity is defined by the holes filling. The second state is characterized by the tightly contacts between the grain surfaces and disappearing of intergrain boundaries. The compressibility in this state is equal to proper compressibility of compounds. Next state, forming under highest pressure is characterized by the creation of new cracks. The pills in this state are crumbly. The successive replacing one state by another may be imaged as a first order phase transition, characterized by the jump of volume at T=0: $v_2 - v_1 = v_2 - v_3 = v_0(1-w_0 w_c^{-1})^{1/2}$. Here $v_i = l_i s$(i=1,2,3), volume at the transition pressure p_1 and p_2; $w_c = k_1 k_2 z_0^2/2(k_2-k_1)$. All other notation are clear from the view of free energies $f = w-TS = w - T[clnc +(1-c)ln(1-c) + ln [(V_{in} - ls)/V_{in}]$. Two first items in rectangular brackets represent configuration entropy (c-the quota of grains with tight integration contacts), third term is the entropy of free volume. The internal energy $w = (1-c)k_1 z_1^2/2 + ck_2(z_2 - z_0)^2/2 + cw_0$, where z_2 is the averaging height of the grains with rigid contacts . The slope of the curve represents dependence of total volume per one grain ($v=sl=s[cz_1 + (1-c)z_2]$) versus pressure permits to define 5 stable phases of pills: 1),5) c=0, powder phases $l=z_1$, $p = k_1 l + T(v_{in} - ls)^{-1}$; 2)4) 0<c<1(intermediate phases), $z_1 = [p-T(v_{in} - ls)^{-1}] / k_1$; $z_2 = z_0+[p-T(v_{in} - ls)^{-1}]/k_2$ $p = p_{1,2}+T(v_{in} - ls)^{-1}(dp/dl = T/(v_{in}^2)$; 3) c=1 (solid phase) , $l =z_2$, $p=k_2(l-z_0) + T(v_{in} - ls)^{-1}$ .The jumps of compressibility,heat capacity and coefficient of thermal expansion satisfy the Erenfest equation. It means that rising the temperature in a course of pills formation makes them more strength even at pressure overcoming the limit p_2, defining the cracks .

P07.10.017 MOLECULAR MODELING OF THE MESOMORPHIC POLYSILOXANES E. Boda, T.V. Timofeeva, N.N.Makarova [1] E.V. Matuhkina [2] [1] Institute of Organoelement Compounds, RAS, 28 Vavilov St.,Moscow, 117813, Russia, [2]Moscow State Pedagogical University, 1 Malaya Pirogovskaya St., Moscow, 119882 Russia

Molecular models of mesomorphic cyclochain organosilicon compounds are presented in our work. These compounds are capable of forming thermotropic mesophases without traditional mesogenic groups [1]. Also, these materials are the only organo silicon compounds which form multilayer LB films [2].To clarify the chain confor mation and mesophase structure the atom-atom potential method [3] was used. The simulations showed that the conformation of the tetrasiloxane cycle depends on t he bulk of the organic substituents. Molecular packing simulations of mesophases of polycyclotetrasiloxane with Me, Et and Pr substituents, based on the X-ray data, reveal structure which resembles columnar liquid crystals.

P07.10.018 MODULATED STRUCTURES IN AN SPATIAL ORDERING OF IMPURITIES WITHIN THE LAYER MESOMORPHIC MEDIUM V. A. Tatarenko and V. Yu. Reshetnyak Dept. of Solid State Theory, Inst. of Metal Physics, 36 Academician Vernadsky Blvd., UA-252680 Kyyiv-142, Ukraine.

Anisotropic phases of the macroscopically homogeneous mesomorphic medium should manifest themselves by specific responses to an external perturbance. Some macroscopical displays are considered in this paper.

The necessary conditions for the origin of a modulated lamellar superstructure in the framework of positional distribution of rigid-sphere-like impurity macroparticles (e.g. macromolecules of very large relative molecular mass or aggregates of small molecules), intruded into a mesomorphic host medium, are analysed within the continuum model of a mesomorphic dispersion-medium phase with nematic-analogous elastic properties, and also by means of both static-fluctulation-wave methods and mean self-consistent-field approximations in statistical-thermodynamic theory of ordering or decomposition reactions for a quasi-lattice-gas model.

Such a partly "ordered" state of an impurity subsystem (e.g. in the early stage of its spinodal decomposition) within a dispersion medium, somewhat similar to the mesomorphic phase called smectic A packing with a spatial periodicity and with a long-range orientational order in mutual arrangement of its elongated ("nonspherical") molecules, is thus typified, with respect to the disordered mutual distribution of impurity macroparticles throughout the nematic host-medium bulk, by a sole breaking of translational symmetry along the direction of the "preferential" orientation of host-medium molecules.

A specific indirect interaction of impurity macroparticies with each other, resulting from interference of static director-field curvatures produced by different impurity macroparticles in a host-medium texture, serves as a co-operative mechanism of structural transformations in a disperse system even for relatively small amounts of impurities (due to the long-range character of this interaction).

Variations in external thermodynamic parameters (temperature etc.) should result in variations of the host-medium-elasticity parameters as well as the Fourier components of the energies of "bending-induced" interactions between impurity macroparticles embedded in the mesomorphic host medium and

thus shift the wave vectors generating the periodic modulations of quasi-stable intermediate superstructures.

These modulated suprastructures within a mesomorphic dispersion medium may be proposed in particular as the objects for further experimental exploration, both in view of the potential for their applications and for their fundamental interest concerning the behviour of dispersed particles in a restricted mesomorphic environment. Gaining information about them is the first necessary step in understanding physical-chemical properties of a mesomorphic disperse system which are associated with its medium-range structure.

The necessary thermodynamic conditions for the appearance of an impurity layer superstructure based on a mesomorphic dispersion medium with smectic-analogous elastic properties are discussed in conclusion allowing for additional long-range indirect, i.e. "strain-induced", interaction between impurity macro-particles as well as the usual direct, for instance Van-der-Waals-type, one. The representative value of energy of the first of these interactions may be considerably changeable with increasing temperature.

P07.10.019 CRYSTALLIZATION AND CRYSTALLOGRAPHY OF SOME LIQUID CRYSTALLINE MATERIALS. Rajnikant and V.K.Gupta, X-ray Laboratory, Post Graduate Department of Physics, University of Jammu, Jammu Tawi - 180 006, India.

An exhaustive literature survey has revealed that very less work has been reported on the single crystalline growth and three-dimensional structural aspects of liquid crystalline materials. Therefore, a variety of liquid crystalline compounds, spread over to three series, were under-taken for the growth of X-ray diffraction quality crystals from slow evaporation technique by using various non-aqueous organic solvent systems. The chance of success for the growth of single crystals, in the present investigation, is not more than 35%. Crystal structures of the materials which could crystallize well have been determined by direct methods. The growth data we have recorded has some interesting features. Growth and the crystallographic data would be presented.

P07.10.020 CRYSTAL STRUCTURE OF LONG CHAIN COMPOUND, 1,10-DECANEDIOL. N.Nakamura and T.Sato, Department of Chemistry, Ritsumeikan University, Kusatsu, Shiga 525-8577, Japan

The crystal structure of 1,10-decanediol was analyzed as one of the model compounds of liquid crystals, because crystal structure of normal long chain compounds is very similar to that of liquid crystals. For example, normal paraffin shows smectic A or smectic C like structure. And some of them exhibit high temperature phase in which molecules rotate around its long axes. A selected crystal of the title compound having approximate dimensions of 0.10 x 0.10 x 0.10 mm was used. The intensity data from a single crystal were collected by RIGAKU AFC5R diffractometer with graphite monochromatized CuKα radiation. The data were collected at a room temperature of 296 ± 1K using θ-2θ scan technique to a maximum 2θ value of 140.0°. The intensities of three representative reflections were measured after every 150 reflections. An empirical adsorption correction based on azimuthal scans of several reflections was applied. The structure was solved by direct methods with SAPI91 and expanded using Fourier with DIRDIF94. The final cycle of full-matrix least-squares refinement was based on observed reflections [I>2.0σ(I)] and 55 variable parameters, $[w(|Fo-Fc|)]^2$ minimized, R=0.040, Rw=0.062. Crystal data obtained are as follows, $C_{10}H_{22}O_2$=174.28, a=21.148(2), b=5.160(2), c=4.9140(4)Å, β=96.69(1)°, $P2_1/a$, Z=2. The structure is very similar to that of homologues with an even number of carbon atoms [1,2].

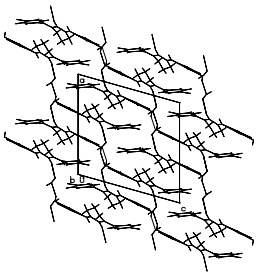
P07.10.021 STRUCTURE OF A LIQUID CRYSTALLINE COMPOUND WITH NLO PROPERTIES. Vedavati G. Puranik, Physical Chemistry Division, National Chemical Laboratory, Pune 411 008, INDIA, Satya V. N. Raju, S. Ponrathnam, Polymer Science and Engineering Division, National Chemical Laboratory, Pune 411 008, INDIA

There has been a lot of interest in designing new organic molecules with NLO properties in view of their numerous applications. It has been found that, if NLO chromophore and nematic, smectic A / C character is incorporated into a molecular structure, a five fold increase in NLO response could be achieved. In this respect π - conjugated systems capped on both ends with electron donor and electron acceptor have been studied. A liquid crystal 2(4 -cyano benzylidine)-6-(4-hydroxy benzylidine) cyclohexanone, nematic in character has been studied by single crystal X-ray diffraction. Compound belongs to monoclinic space group $P2_1/n$ with a=14.545 (3), b=7.796 (2), c=15.324 (2) Å, β=105.69 (2) °, Z=4 and has been refined to R=0.061. The centrosymmetric dimers are formed by hydrogen bonds through keto group and water molecules. Further these hydrogen bonded dimers are



linked via water molecules to form a supramolecular organization. The π - π interaction has been observed between the aromatic benzylidine rings. This donor-acceptor π conjugated aromatic chain greatly stabilizes the NLO property mainly due to the hyper polarizability. When this chromophore is extended at the donor end through a polymethylene spacer and grafted on to an atactic polymeric backbone, NLO effects have been observed after poling.

P07.10.022 PHASE TRANSITIONS AND WATER DYNAMICS IN $[Mn(H_2O)_6](ClO_4)_2$, STUDY BY NEUTRON SCATTERING METHODS. I Natkaniec, Frank Laboratory of Neutron Physics, JINR, 141980 Dubna, Russia, and H. Niewodniczanski Institute of Nuclear Physics, 31-342 Krakow, Poland, E. Mikuli and A. Migdal-Mikuli, Department of Chemical Physics, Jagiellonian University, 30-060 Krakow, Poland.

The hexaaquametal(II) chlorates(VII) form at room temperature body centered orthorhombic-pseudohexagonal structures (***Pmn2***$_1$ - C^7_{2v}) with two metal ions per unit cell [1]. Phase transitions in these compounds have been detected by many methods, however exist considerable disagreement concerning the transition temperatures and even the number of phases, especially with Me=Mn, Fe and Co [2]. Following transition temperatures were detected for $[Mn(H_2O)_6](ClO_4)_2$ by: calorimetry - 323, 247 and 135K, NMR - 160 and 89K, magnetic susceptibility - 120K, IR and RS - 341, 248 and 161K. We have study this compound by neutron powder diffraction (NPD) and inelastic incoherent neutron scattering (IINS) in the temperature range of 290 - 20K. The NDP and IINS spectra were measured simultaneously by time-of-flight method on the NERA spectrometer [3] at the high

flux pulsed reactor IBR-2 at Dubna. At the room temperature water molecules perform fast stochastic reorientations at the rate of THz phonon frequencies. Disorder characteristic for the room temperature can be easily overcooled and frozen. Even relatively slow cooling of ca. 40K/hour from 290 to 100K, freeze an metastable orientational (protonic) glass phase below ca. 160K. Below ca. 90K structural phase transition was observed by the NDP, however the IINS spectra indicate the pure ordered low temperature phase only after annealing the sample a few hours at 100K. At heating structural phase transition take place at ca. 120K, and at ca. 200K water molecules starts fast reorientations in crystalline structure of the room temperature phase.

P08.10.001 $LiMn_2O_4$, $LiMxMn_{2-x}O_4$ CATHODE MATERIALS: SYNTHESIS OF BULK MATERIALS BY SOL-GEL AND FABRICATION OF THIN FILMS BY ELECTRON BEAM, THERMAL EVAPORATIONS AND SPRAY PYROLYSIS. Tran Dai Lam, Department of General and Inorganic Chemistry, Hanoi University of Technology, 1 Dai Co Viet, Hanoi, Vietnam. Ngo Quoc Quyen, Laboratory of Applied Electrochemistry, Institute of Chemistry, National Centre for Natural Sciences and Technology, Nghiado, Caugiay, Hanoi, Vietnam.

The spinel $LiMn_2O_4$ has been studied extensively as a positive material for lithium ion batteries. In the paper, we report sol-gel citrate procedure for synthesising the bulk $LiMn_2O_4$ and $LiM_xMn_{2-x}O_4$ (M= Co,Ni, Cu) (x£ 0,5) , based on polymerisation reaction of citric acid and via carbonyl groups in metal acetates (without Ethylene Glycol, used in Pechini process). TA data (SHIMADZU TA-50) indicates that the violent combustion of organic groups in xerogels seem to set up the spinel formation at much lower firing temperature than that of solid state reaction. The xerogel structure has been explored by IR spectroscopy (IMPACT FTIR-410) and TEM (magnification 100000 times). The excellent phase purity and 3d substution of materials has been verified by X-Ray Diffraction (SIEMENS D-5000). This substution is believed to enhance the structural stability of electrode during insertion/extraction lithium ions, maintaining the cubic symmetry (Fd3m).

Thin film fabrication is a good solution to improve the electrochemical performance of electrode. Therefore, electron beam, thermal evaporations and electric spray pyrolysis are applied for this purpose. In the electron beam evaporation, the starting bulk $LiMn_2O_4$ is used. The substrate is ITO, the oxygen pressure is 5.10-4Torr. Two-source thermal evaporation, each of these sources is used for Mn acetate and Li carbonate (taken in proper mole ratio). Spray pyrolysis from the acetate solution of Mn, Li and doped 3d metals at 300-4000C is also successfully adapted. All thin films obtained by these methods have been compared structurally with the bulk materia by using XRD and SEM and investigated electrochemically by Cyclic voltamettry (CV) and Impedance Spectroscopy (EIS).

P08.10.002 POLYMERS OF SINGLE WALL NANOTUBES: GEOMETRY AND DIFFRACTION PATTERN MODELING. L.A. Chernozatonskii, Institute of Biochemical Physics, 117977 Moscow, RUSSIA, N.R. Serebryanaya, Center of Superhard Materials, 142092 Troitsk, RUSSIA

Modelling of polymerized carbon single-wall nanotubes (SWNT), which are possible to prepare under high pressures and temperatures, are represented.

We have considered the following polymers and restructured figures of (n,0) and (n,n) nanotubes and their X-ray diffraction patterns:

Chain structures of polymerized identical SWNT's with 2+2 and Osawa's rectangle bonds (changing of tube geometry from cycle to oval; X-ray diffraction patterns of a chain polymerized SWNT crystal, and graphite-like needle, transformed from SWNT rope via NT chain polymerization);

SWNT zeolites in which NT polymerization occurs by bonding of 6 sp^3 atomic pairs in each NT unit cell with similar atomic pairs located on 6 neighbouring tubes alike 2+2 cycladditions in rhombic C_{60} polymer layer (geometry optimization, and X-ray diffraction patterns).

This work was supported by Russian Fund for Fundamental Research.

P08.10.003 A NEW FORM OF CRYSTALLINE LAYERERD CARBON: CHARACTERISATION, STABILITY AND ELECTRONIC PROPERTIES. M. Terrones[a,b], J-C. Charlier[c], N. Grobert[a], P. M. Ajayan[d] and H. Terrones[b], [a] School of Chemistry, Physics and Environmental Science, University of Sussex, Brighton, BN1 9 QJ, United Kingdom, [b] Instituto de Física, UNAM, Apartado Postal 20-364, 01000 México, [c] UniversitÈ Catholique de Louvain, Unite PCPM, Place Croix du Sud 1, 1348 Louvain-la-Neuve, Belgium, [d] Department of Materials Science & Engineering, Rensselaer Polytechnic Institute, Troy, NY 12180-3590, U.S.A.

Soon after Carbon nanotubes were identified by Transmission Electron Micorscopy (TEM), their electronic and mechanical properties were thought to be remarkable. In this context, early theoretical calculations predicted that these rolled graphene sheets could behave as metals or semiconductors depending upon diameter and the hexagonal pattern along the direction of the tube axis (helicity). Recent local density of states measurements on different single-walled carbon nanotubes revealed that they can indeed be either metals or semiconductors depending on small variations in the chiral angle or diameter. Furthermore, Young´s moduli studies show that the single and multi-walled carbon nanotubes are much stronger than steel and conventional carbon fibres and are extraordinarily flexible when subjected to large strain.

In this account, We propose novel crystals consisting of layered sp^2-like carbon, containing periodic arrangements of pentagons, heptagons and hexagons. The proposed layered crystals exhibit stable hexagonal, orthorhobic (Fig. 1a) and monoclinic structures. In addition, these sheets are rolled so as to generate carbon nanotubes (Fig. 1b) with intriguing electronic properties. Local density of states (LDOS) calculations of all crystals and tubes revealed an intrinsic metallic behaviour, independent of orientation, tube diameter and chirality. Interestingly, all nanotubes exhibit Van Hove singularities as a signature of 1D systems. Particularly, an unusual high intensity LDOS peak at the Fermi level is noticed for the hexagonal crystal and its respective nanotubes, thus suggesting the possible existence of superconductivity. For all capped nanotubes, localized states appear close to the Fermi energy when approaching the nanotube end, thus implying an enhancement of the field emission current. X-ray and electron diffraction simulations of the proposed nanostructures are also studied, and

possible synthetic routes to this new family of covalently bonded layered materials are discussed.

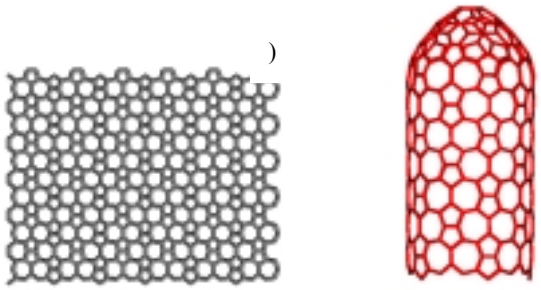

Fig 1. (a) Carbon layer of the orthorhombic crystal consisting of pentagons and heptagons only. It is noteworthy the periodicity of the carbon rings; (b) a nanotube generated by rolling up the carbon layer depicted in a, the cap contains additional pentagons for closure. Tight binding calculations show that both structures are metallic.

P08.10.004 STRUCTURAL STUDIES ON SOME IONIC AND MIXED CONDUCTORS BASED ON Li_4GeO_4. R.P. Gunawardane, M.A.K.L. Dissanayake and H.H. Sumathipala Faculty of Science, University of Peradeniya, Peradeniya, Sri Lanka

Three new types of Li_4GeO_4 based solid solution with γ-LISICON structure have been found. In the Li_4GeO_4- Li_3CrO_4 binary system[1], an extensive range of solid solutions $Li_{3+x}Cr_{1-x}Ge_xO_4$ with γ-LISICON structure has been found with probable solid solution mechanism $Cr^{5+} \rightarrow Li^{+} + Ge^{4+}$. These solid solutions are unusual in that it contains Cr^{5+}. X-ray powder diffraction data for the γ solid solution can be indexed on an orthorhombic unit cell, Pmnb. It is very similar to other γ-phases such as γ -Li_3PO_4 and LISICON. Li^{+}ion conductivity increases with x; at x=0.90,(bulk), $1.4x10^{-5}$ S cm^{-1} at 27^0C rising to 0.044 S cm^{-1} at 300^0C. These ionic conductivities are among the highest found for solid Li^{+}ion conductors in the LISICON/γ family.

In the Li_4GeO_4-Li_2CoGeO_4 system, a new LISICON type γ-solid solution range with formula $Li_{4-2x}Co_xGeO_4$ has been found for $0.15<x<0.8$. Powder X-ray diffraction data for the γ-solid solution can be indexed on an orthorhomsic unit cell, Pmnb, similar to γ-Li_3PO_4 structure. The highest net conductivity, $8.4x10^{-6}$ Scm^{-1}, was observed for x=0.25 at 27^0C, charge/discharge polarization measurements and low frequency a.c. impedance measurements show the occurrence of mixed Li^{+} ion and electronic conductivity in the material.

In the Li_4GeO_4-Li_2SO_4 binary system, a new LISICON type γ solid solution range with formula $Li_{4-2x}Ge_{1-x}S_xO_4$ has been found for $0.08<x<0.42$. The γ-solid solutions are structurally related to orthorhombic γ-Li_3PO_4 and contain interstitial Li^{+}ions.

P08.10.005 DEFECT STRUCTURE AND LATTICE HEAT CAPACITY OF ZIRCONIA. T. Atake and T. Tojo, Materials and Structures Laboratory, Tokyo Institute of Technology, Yokohama, 226-8503 JAPAN, and T. Mori, National Institute for Research in Inorganic Materials, Tsukuba, 305-0044 JAPAN, and H. Yamamura, Faculty of Engineering, Kanagawa University, Yokohama, 221-8686 JAPAN, and O. Yamamoto, Faculty of Engineering, Mie University, Tsu, 514-8507 JAPAN.

The heat capacities of zirconia (ZrO_2) have been measured for the three polymorphs of monoclinic, tetragonal and cubic structures between 13 and 300 K using a high precision adiabatic calorimeter [1,2]. The latter two polymorphs, which are the high temperature forms of zirconia, are stabilized down to room temperature by yttria- or scandia-doping, while pure zirconia undergoes phase transition and the structure is of monoclinic at room temperature. Several samples of various doping at most 11 mol % of yttria or scandia were used for the present study. Highly doped samples are of cubic and lower doped samples are of tetragonal. It has been found that the doped samples have excess heat capacity at low temperatures compared with pure zirconia. The excess heat capacity decreases with increasing doping. However, the detailed mechanism in the stabilized zirconia has not been clarified yet. In the present study, molecular dynamics simulation has been performed and the calculated phonon density of states are successfully compared with the measured heat capacities.

P08.10.006 *IN SITU* XRD STUDIES OF GRAPHITE ELECTRODES IN THE Li-ION BATTERY. Kristina Edström, Inorganic Chemistry, Ångström Laboratory, Uppsala University, Box 538, SE-751 21 Uppsala, Sweden

Diffraction techniques are valuable for studying structural change in battery electrode materials at an atomic level. There are many examples of the use of X-ray diffraction in determining cell parameters, for phase identification and for assessing crystallinity connected to battery research. Several non-standard methods can be exploited, however, to provide a more detailed understanding of atomic-level processes in Li-ion or Li-polymer batteries. This will be illustrated here with examples taken from potential anode materials. A number of features will be addressed: phase analysis; structural changes on lithium insertion; temperature dependence of structural changes; lithium insertion mechanisms; structural kinetics. The *in situ* X-ray diffraction methods demonstrated are all performed in transmission mode using a STOE position-sensitive detector (PSD) powder diffractometer.

The Li-ion battery comprises a transition-metal oxide cathode, an anode material which serves as lithium-ion host, and a mechanical separator soaked in some lithium salt solution as electrolyte. The anode currently used in commercial Li-ion batteries is a carboneous material, typically graphite. In this work, graphite is studied at low voltage against a Li counter-electrode.

Some results will be presented from structural studies which will illustrate the performance of the graphite electrode at both ambient and elevated temperatures and under conditions of pulsed charging/discharging, as occurs in mobile-phone applications.

P08.10.007 STRUCTURE OF CATHODE AND ITS RELATION TO CAPACITY FADE IN LI-SPINEL BATTERY. T. Kamiyama, I. Nakai[a], Y. Terada[a], S. Gotoh, K. Oikawa[b], Y. Shiraishi[a], F. Nishikawa[c] and F. Izumi[d], Institute of Materials Science, University of Tsukuba, Tsukuba, Ibaraki 305-8573, Japan, [a]Department of Applied Chemistry, Science University of Tokyo, Kagurazaka, Tokyo 162-0825, Japan, [b]Advanced Science Research Center, JAERI, Tokai, Ibaraki 319-1195, Japan, [c]Asahi Chemical Industry Co. Ltd., Kawasaki, Kanagawa 210, Japan, [d]National Institute for Research in Inorganic Materials, Tsukuba, Ibaraki 305-0044, Japan.

Although $LiCoO_2$ is widely used for cathodes in commercial Li-ion batteries, a spinel-type oxide, $LiMn_2O_4$, is now intensively studied commercially because it is preferable in terms of the large abundance and safety, i.e., cheap and non toxic. However, inferior charge/discharge properties should be overcome before application.

The relation among crystal structures, microstructures and cycling performance of batteries will be revealed through in situ neutron diffraction. However, in situ neutron diffraction is not easy because a battery cell consists of various components which prevent precise structure determination. Choice and arrangement of those components is important to clarify what occurs in the structure and which is harmful for the cycling performance.

With the Li-spinel cell developed for neutron diffraction experiments, unwanted Bragg reflections were minimized. After 50% charging, the occupancy of a Li site decreases with little change in the rest of the structure. However, after deep charging, phase separation occurred and two phases with different Li content emerged. In the phase of lower Li content, Li ions are most likely to occupy at 16c site in addition to original one. We speculated that the second phase is unstable in the electrolyte. This is consistent with the fact that deep charging degrades the cycling performance.

P08.10.009 FLUORITE RELATED SUPERSTRUCTURE OF A NEW OXYPHOSPHATE OF LEAD AND BISMUTH : $Pb_4Bi_{19}P_4O_{42.5}$. Sophie Giraud[1,2], Jean-Pierre Wignacourt[1], Michel Drache[1], Pierre Conflant[1], Hugo Steinfink[2], [1]Laboratoire de Cristallochimie et Physicochimie du Solide, URA CNRS 452, ENSCL, BP 108, 59652 Villeneuve d'Ascq Cedex, France ; [2]Texas Materials Institute, Department of Chemical Engineering, University of Texas, Austin, Texas 78712, USA.

The structure of a new oxyphosphate with high bismuth content, $Pb_4Bi_{19}P_4O_{42.5}$, can be derived from the cubic δ-Bi_2O_3 [1] structure, which itself is a CaF_2 (fluorite) structure derivative. The initial F centered cubic cell of δ-Bi_2O_3 (a = 5.648 Å) can be transformed to a smaller tetragonal I centered cell, a, b = 3.9 Å and c = 5.5 Å . Weissenberg photographs and the X-ray data collected on a single crystal of $Pb_4Bi_{19}P_4O_{42.5}$ show weak superstructure reflections leading to a pseudo orthorhombic cell with parameters a = 11.885(2) Å, b = 11.540(2) Å, c = 15.636(3) Å and β = 90.23(3)°. The cell is I centered. The oxyphosphate can be described by a 3 x 3 x 3 superstructure derived from the fluorite "small cell". The structure was solved in the monoclinic system, superstructure cell space group I2, using X-ray synchrotron data, λ = 0.1602 Å, which avoids an absorption correction. The structure refinement converged to R<0.05. The atomic positions of the heavy atoms adopt an orthorhombic symmetry, but the oxygen atoms reduce the symmetry to monoclinic. The details of the structure will be presented.

We thank Dr. Richard Harlow for the synchrotron data collection.

P08.10.010 THE CHALLENGE OF X-RAY DIFFRACTION RESIDUAL STRESS MEASUREMENTS ON HELICAL COMPRESSION SPRINGS. C. K. Lowe-Ma, A. R. Drews, and A. R. Krause, Ford Research Laboratories, Ford Motor Company, Dearborn, MI 48121, USA.

Helical compression springs used for suspension in automobiles must meet specific requirements for loading, operating stress range, fatigue life, mass and space constraints, and geometrical tolerance under various temperature and corrosion conditions. Compression springs that are produced by the cold coil method have an advantage in surface quality over those produced by hot coiling that translates to a smaller diameter wire for equivalent operating stresses. However, in the production of cold-coiled springs, several manufacturing steps affect the final fatigue performance of the spring. The variables in these processing steps must be optimized and remain constant to attain the specified fatigue life. The residual stress profile in compression springs is an excellent gauge of the processing parameters and of any changes occurring during production runs. X-ray diffraction can be used to measure the residual stresses, but, in reality, conducting X-ray diffraction-based residual stress measurements on a spring (without destroying the spring!) present a challenge. Fundamental issues and selected results from laboratory and production plant measurements of X-ray diffraction-based residual stress will be presented and discussed in the context of process monitoring.

P09.10.000 THE CALCULATION OF ANHARMONIC MOTION AND DISORDERING OF CATIONS IN THE STRUCTURE OF $K_{1-X}Tl_XTiOPO_4$ CRYSTALS. D.Y.Lee, Department of electrical materials, Korea Electrotechnology Research Institute

Precise X-ray structural analysis of $KTiOPO_4$(KTP) type single crystals often meets the difficulties in analysis of electron density distribution around the positions of one valance cations, which locate in the channels between hard frames of TiO_6 octahedron chains and PO_4 tetrahedron. In these positions significant residual peaks are found on the difference Fourier map of electron density after anisotropic refinement of crystal structure in some crystals of this type. This means that further refinement is necessary for more exact decision of these structures. In this case, in order to solve this problem, two models can be suggested: 1. dynamic model of anharmonic motion of atoms and 2. static model of disordering of atoms in these positions.

In this study, these two models were applied for solving the problems of residual peaks around the positions of (K, Tl) cations on the difference Fourier map of electron density in the structural of $K_{1-x}Tl_xTiOPO_4$ crystals, in which x = 0.18, 0.41 and 1.

Anharmonic refinement of thermal parameters of (K, Tl) atoms were calculated to 6^{th} rank tensor by Gram-Charlier and Edgeworth expansions, using program PROMETHEUS. [1]

Structural analysis of disordering has difficulties, connected to strong correlation between some parameters of atoms in seperated positions, including coordinates, occupancies and thermal parameters. These difficulties were solved by step-by-step scanning method.[2]

P09.10.001 STRUCTURAL CHARACTERISTICS OF FLUX GROWN CRYSTALS OF THE $NdAl_3(BO_3)_4$-$GdAl_3(BO_3)_4$ SYSTEM. G.Bocelli and L.Righi, CSSD-CNR, University of Parma, Parma-43100, Italy, N.I.Leonyuk and E.V.Koporulina, Moscow State University, Moscow-119899, Russia.

The solid solutions based on the system $NdAl_3(BO_3)_4$-$GdAl_3(BO_3)_4$ (NAB-GAB) belong to the famous family of polyfunctional orthoborates with device potential [1]. Of these materials, the non-centrosymmetric Nd_xGd_{1-x} $Al_3(BO_3)_4$ (NGAB) crystals are promising materials for non-linear optics and self-frequency-doubling lasers [2]. Low-temperature forms of the end members of these solid solutions belong to the non-centrosymmetric huntite *R32* space group, but the high forms of NAB and GAB crystals have the centrosymmetric monoclinic space groups *C2/c* and *C2* respectively. The purpose of this work was to find a correlation between the growth conditions, compositions, and structural characteristics of these solid solutions.

The crystals of NAB, GAB and GYAB were grown by both TSSG and spontaneous nucleation using a $K_2Mo_3O_{10}$ based flux. The Nd, Gd and Mo concentrations in the crystals obtained

were measured by microprobe analysis. The neodymium distribution coefficient K is usually close to 1, but it slightly depends on the crystal growth conditions. The structures of NAB, $Nd_{0.17}Gd_{0.83}Al_3(BO_3)_4$ and GAB crystals obtained under different growth conditions were refined. As a result, a correlation between the crystal structure, growth conditions and compositions of the grown crystals will be discussed.

P09.10.002 CRYSTALLISATION AND STRUCTURAL CHARACTERISATION OF La,Nd BOROSILICATES. E.P.Shvanskii, N.I.Leonyuk, E.L.Belokoneva, Department of Crystallography, Moscow State University, Moscow 119899, Russia, and G. Bocelli, L. Righi, Centro di Studio per la Strutturistica Diffrattometrica CNR, Viale delle Scienze, Parma 43100, Italy

The $LaBSiO_5$ crystals with the stillwellite type structure belong to the new ferroelectric family, and at the same time, they possess non-linear optical (NLO) and piezoelectric properties [1]. Neodymium doped stillwellite crystals can be considered as a new laser materials.

Crystals of stillwellite-like La and La,Nd borosilicate were obtained from high temperature solutions. Also, new La borosilicate, $La_3BSi_2O_{10}$ was obtained by this method. The choice of fluxes was based on the potassium trimolybdate with an excess of lithium and potassium fluoride. The composition of grown crystals was studied by electron microprobe analysis, and powder diffraction patterns were determined for all the crystals. Results of detailed structural study will be presented for all the crystals.

Some aspects of the synthesis of new La and La,Nd borosilicates with controlled and desirable composition, structure and properties will be discussed.

P09.10.003 $(Y,Gd)Al_3(BO_3)_4$ AND $(Y,Nd)Al_3(BO_3)_4$ SOLID SOLUTIONS WITH DEVICE POTENTIAL: CRYSTAL GROWTH, COMPOSITION AND STRUCTURE E.V.Koporulina and N.I.Leonyuk, Geological Faculty, Moscow State University, Moscow 119899, Russia, and A.V.Mokhov, Institute of Ore Deposits Geology, Petrography, Mineralogy and Geochemistry RAS, Staromonetny 35, Moscow 109017, Russia.

Non-centrosymmetric solid solutions based on the $(Nd_xY_{1-x})Al_3(BO_3)_4$ (NYAB) system are excellent materials for self-frequency-doubling lasers, and $(Gd_xY_{1-x})Al_3(BO_3)_4$ (GYAB) crystals have considerable potential for the application of high frequency acoustic wave devices in the 8-9 GHz range [1]. However, there are problems to obtain these solid solutions with desirable structure and homogeneity because the YAB belongs to the R32 sp. gr., but each of other end members exists, at least, in two polymorphic modifications: R32 and C2/c sp. gr. (NAB), R32 and C2 sp. gr. (GAB). In this work, the structures, composition and homogeneity of these solid solutions have been studied depending on the growth conditions.

The crystals of NYAB (x=0.05, 0.1, 0.6, 0.75) and GYAB (x=0.1, 0.2, 0.3, 0.4, 0.6, 0.65, 0.7 and 0.75) were grown by both spontaneous nucleation and TSSG from a $K_2Mo_3O_{10}$-containing fluxed melts in the temperature ranges 1060-990°C and 1050-1010°C respectively. The structures of the NYAB (x=0.75) and GYAB (x= 0.65, 0.7 and 0.75) crystals have been studied.

The temperatures and concentration ranges of phase transitions are determined using X-ray technique, EMPA, optical and electron microscopies.

P09.10.004 NEUTRON AND X-RAY DIFFRACTION STUDY OF YTTRIUM-ALUMINIUM BORATE. E. Sváb, Gy. Mészáros, E. Beregi, Research Institute for Solid State Physics and Optics, H-1525 Budapest, POB 49 and M. Tóth, Hungarian Academy of Sciences Laboratory for Geochemical Research, H-1112 Budapest, Budaőrsi str. 45, Hungary

Yttrium-aluminium borate – $YAl_3(BO_3)_4$ (YAB) single crystals have excellent non-linear optical properties, and the doped YAB crystals are important for building microchip lasers. Pure and doped (Cr, Ga) YAB single crystals were grown by top-seeded high temperature solution (flux) method. The single crystals were powdered into fine grains to obtain good powder spectrum suitable for Rietveld refinement. The measurements were performed using the PSD neutron diffractometer (λ=1.0577 Å) at the 10 MW Budapest research reactor and a Philips X-ray diffractometer with monochromatic $CuK_{\alpha 1}$ (1.5406 Å) radiation. The starting parameters for data treatment were taken from [1]. The space group is hexagonal R32 (No.155) with trigonal symmetry. The results for pure YAB are summarised in Table 1. Refined crystallographic parameters will be presented for doped YAB crystals as well.

Table 1. Crystallographic data for $YAl_3(BO_3)_4$.

P09.10.005 LINEAR AND NONLINEAR OPTICAL PROPERTIES OFBiB_3O_6 (BIBO) H. Hellwig, J. Liebertz, L. Bohatý, University of Cologne, Institute of Crystallography, Zülpicher Str. 49 b, D-50674 Köln, Germany

Finding new materials for nonlinear optics is still a current topic because of the increasing variety of applications. Borates are a large reservoir of non-centrosymmetric crystals with the nonlinear optically efficient $[BO_3]$ group.We determined the linear and nonlinear optical properties of the monoclinic bismuth borate BiB_3O_6, abbreviated as BIBO [1]. BIBO crystallizes monoclinic in the polar space group C2. Its structure consists of distorted $[BO_3]$ triangles and $[BO_4]$ tetrahedra in ratio 2:1 which form sheets, linked by six-coordinated bismuth cations [2]. The lone pair of the bismuth atom seems to play an important role for the stability of the crystal structure and its properties. Single crystals were first grown by Liebertz. Becker improved the growth method and grows large single crystals of optical quality with dimensions of several centimeters [3].The linear optical properties allow a wide range of phase matching processes. Due to the symmetry (one 2-fold axis only), there are 8 independent nonlinear optical coefficients d^{SHG}_{ijk} which describe second harmonic generation. We used the *Maker* fringe technique and special software for data evaluation to determine all of the 8 coefficients and their relative signs. With these data we are able to calculate most of the

nonlinear optical processes in a quantitative manner.We will present the results of this measurements and will demonstrate solutions for problems arising, if *Maker* fringe curves are to be analyzed. With our methods we are able to recalculate the measured curves with hardly any systematic discrepancy considering of multiple reflections and *Fabry-Perot* interferences [4].

P09.10.006 CRYSTAL GROWTH AND SPECTROSCOPIC PROPERTIES OF RE : BiB_3O_6 (RE = Pr, Gd, Eu, Er). *P. Becker and **C. Wickleder, University of Cologne, *Institute of Crystallography, Zülpicher Str. 49 b, 50674 Köln, Germany; **Institute of Inorganic Chemistry, Greinstr. 6, 50939 Köln, Germany.

During the last 15 years, compounds of the borate group turned out to be interesting materials for nonlinear optical applications. They are superior in UV-applications to other commonly used NLO materials like KH_2PO_4 or $LiNbO_3$ because of their high UV-transmittance combined with a high damage threshold. Bismuth triborate, BiB_3O_6, is a new, very promising material for nonlinear optics with a d_{eff}^{SHG} which is higher than that for most other materials being in use for applications, like $KTiOPO_4$, β-BaB_2O_4 or LiB_3O_5 [1]. It crystallizes in the monoclinic, polar space group C2; the structure consists of borate layers built by [BO_4] tetrahedra and [BO_3] triangles in a ratio of 1:2, alternating with layers of 6-fold coordinated Bi atoms [2].

Crystals of BiB_3O_6 were doped with the rare earth elements Pr, Gd, Eu and Er in order to combine its high frequency conversion capability with the host for potentially luminescent ions in one crystal. Large single crystals of doped BiB_3O_6 were grown from highly viscous melts with concentrations of 0.5 mole% RE_2O_3 (RE = Pr, Gd, Eu, Er), respectively. Crystals of good quality with sizes up to 12 x 12 x 18 mm^3 were obtained by using the top seeding technique and with growth parameters similar to those used for undoped BiB_3O_6 [3].

To characterise the crystal field levels of the rare earth ions in the host lattice, we present absorption spectra in the wavelength range from 200 nm to 2000 nm, measured with an absorption spectrometer (Varian, Cary 5E). For the knowledge of the phonon energies, IR- and Raman spectra were recorded (Bruker, IFS 66V/S and FRA 106/S).

P09.10.007 STRUCTURE AND PROPERTIES OF THE CRYSTALS IN THE $RbTiOPO_4$-$CsTiPO_5$ SYSTEM. Liu Wen, V.I.Voronkova, and V.K.Yanovskii, Department of Physics, Moscow State University, Moscow 119899, Russia, and N.I.Sorokina, I.A.Verin and V.I.Simonov, Institute of Crystallography RAS, Moscow 117333, Russia.

Potassium titanyl phosphate $KTiOPO_4$ and other crystals of this family are of great interest as nonlinear optical materials, ferroelectrics and superionic conductors. The present paper deals with the precise X-ray analysis and some physical properties of the mixed composition crystals in the system $RbTiOPO_4$ (RTP)-$CsTiPO_5$ (CTP) with the main attention paid to solid solutions on the base of RTP.

The investigations of the RTP-CTP system in the subsolidus region shows that it is pseudobinary one with the limited solid solutions $Rb_{1-x}Cs_xTiOPO_4$ of the KTP-type structure and $Cs_{1-x}Rb_xTiPO_5$ of pyrochlore-type. The width of the former solution area is $0<x<0.2$ at 700°C and diminishes as the temperature increases. At higher temperatures and higher Cs concentrations the pyrochlore-type structure is more stabile. The unit cell parameters of RTP:Cs and CTP:Rb solutions obey well the Vegard law.

Single crystals of $Rb_{1-x}Cs_xTiOPO_4$ with x=0.00, x=0.05 and x=0.11 were grown with the use of flux method from melts of Rb_2O-Cs_2O-TiO_2-P_2O_5 system and their atomic structures were refined by means of precise X-ray analysis. The partial substitution of Rb by Cs leads to the increase of the unit cell parameters *a* and *b* and to more loose crystal structure with incomplete occupation of Ti, P and O positions. Cs atoms show tendency to occupy mainly one of two possible positions having more large coordination with oxygen. The distortion of TiO_6 octahedra, responsible partially for the appearance of spontaneous polarization at the ferroelectric transition, decreases with this substitution.

Temperature dependencies of the dielectric permeability ε_{33} and electrical conductivity σ_{33} of the $RbTiOPO_4$ and $Rb_{0.95}Cs_{0.05}TiOPO_4$ single crystals are studied. A small substitution of Rb by Cs results in the lowering of ferroelectric transition point by 20°C and to increasing of ionic conductivity by about one order of magnitude.

P09.10.008 THE CRYSTAL STRUCTURES OF TWO EXTENDED π-BRIDGED OPTICALLY NONLINEAR CHROMOPHORES. G.J. Gainsford and A.D. Woolhouse, Industrial Research Limited, Gracefield Road, Lower Hutt, New Zealand and R.A. Myers and T.H. Barnes, Department of Physics, University of Auckland, Private Bag 92019, Auckland, New Zealand.

As part of our research effort to make usable $\chi^{(2)}$ polymers from tetherable equivalents of a number of accessible high β chromophores, we were able to produce crystals of representatives of two extended π-bridge systems: 6-[4-N,N-Bis(2-hydroxyethyl)amino]phenylene-4-(dicyano)methylidene-2-methyl-4*H*-pyran (I) and 5-{3-[4-N,N-Bis(2-hydroxyethyl)amino]-phenylene-5,5-dimethyl-2-cyclohexen-1-ylidene}-1,3-dimethyl-1,3-dihydro-2-thioxo-1*H*,5*H*-pyrimidine-4,6-dione (II). Both are characterized by the presence of *hetero*aromatisable acceptors that should, in principle proffer energetic compensation for the loss of aromatic stabilization in the donor moiety.

(I) Crystallizes in P-1, *a*=7.3398(3), *b*=10.4970(5) ,*c*= 7.3398(3) Å, α 79.705(2), β 80.925(2), γ 81.989(2) deg, V 941.06(7) Å^3, Z=2. It contains discrete molecules of $C_{21}H_{21}N_3O_3$ hydrogen bonded via the hydroxyl hydrogen atoms to adjacent oxygen and cyano-nitrogen atoms (s).

(II) $C_{28}H_{32}N_3O_4S$ crystallizes in P 2_1/c, *a*=19.0643(12), *b*=9.2783(6), *c*= 16.9017(11) Å, β=90.462(1)°, with an ethanol molecule of crystallization (Z=4, V=2980.6(3) Å^3). The two molecules form an hydrogen-bonded infinite two-dimensional network.

Bond length alternation values (*bla*) [A] and the results of other measurements will be presented.

P09.10.009 $LiNBO_3$ REVISITED. B. Etschmann, N. Ishizawa, Y. Matsushima & K. Suda-Saito, Materials and Structures Laboratory, Tokyo Institute of Technology, 4256 Nagatsuta, Midori-ku, Yokohama 226, Japan

$LiNbO_3$ is a ferroelectric material which has been studied extensively due to its wide range of applicability in linear and non-linear optical and acoustic devices. Optimal use of lithium niobate in such devices depends on the Li:Nb ratio, as this critically affects many physical properties of the sample. This has resulted in numerous types of investigations, including single-crystal diffraction experiments, to determine the Li:Nb ratio. However, previous single crystal studies suffered severely from extinction [e.g. 1-2], and corrections for extinction and anharmonic thermal vibrations may affect the calculation of the Li:Nb ratio [3].

Extinction effects may be reduced by using a smaller crystal, thus diffraction data was collected on an eight micron lithium niobate crystal at BL14A, Photon Factory, in Tsukuba, Japan. Preliminary refinements indicate that the extinction is virtually negligible (y_{min} = 0.97), with an R-factor around 1%. The atoms vibrate anisotropically, however, no pronounced anharmonicity has been detected. Electron density maps have similar features to maps published previously, such as an accumulation of electrons around Li, but the features are much less pronounced.

P09.10.010 NEUTRON DIFFRACTION STUDIES ON MIXED CRYSTALS OF $RbTiOAsO_4$ AND $CsTiOAsO_4$. Jörgen Albertsson, Jenni Almgren and Göran Svensson, Department of Inorganic Chemistry, Chalmers University of Technology, SE - 412 96 Göteborg, Sweden (jean@inoc.chalmers.se).

The $KTiOPO_4$ isomorhpic family consists of $MTiOXO_4$ compounds where M, among others is K, Rb, or Cs and X is P or As. These materials are known for their non-linear optical properties. In IR generating laser experiments the arsenates are needed as these have higher transmission than phosphate analogues. It is very difficult to get large CTA crystals of optical quality and we are therefore growing mixed crystals of RTA and CTA. Spontaneously grown crystals measure up to $3 \times 3 \times 3$ mm and even larger pieces of optical quality can be cut from top seeded grown crystals.

RTA and CTA have network structures of AsO_4 tetrahedra and TiO_6 octahedra with chains of - AsO_4 - TiO_6 - AsO_4 - TiO_6 - along the *a*, *b* and *ac* directions. The Ti atoms in the octahedra are displaced, giving long and short Ti - O bonds that are partially responsible for the optical non-linearity. The network has open channels along the *c* axis with two different sites for the cation. Powder data has been collected for three different mixtures of RTA and CTA together with the pure compounds. This is done to study the coordination sites and to determine the Rb/Cs occupancies in different mixtures.

Single crystal X-ray diffraction studies show odd displacement parameters, which are probably due to the high absorption of the heavy atoms causing problems with the absorption correction. An improved structure model is needed for precision electron density studies [1], and for this purpose 1466 reflections has been collected at 295 K using neutron single crystal diffraction. The RTA sample used in this experiment was cut to the size $5 \times 3 \times 2$ mm^3 in *a*, *b* and *c* directions.

P09.10.011 CRYSTAL STRUCTURE AND PIEZO-ELECTRIC PROPERTIES OF La-, Pr- AND Nd-LANGASITE. [1]H. Ohsato, [2]H. Morikoshi, [1]D. Sakakibara, [1]K. Suito, [2]J. Sato, [2]K. Kawasaki and [1]K. Tanaka, [1]Nagoya Institute of Technology, Gokiso-cho, Showa-ku, Nagoya 466-8555, Japan, [2]Materials Research Center, TDK Co., Matugashita 570-4, Minamihatori, Narita 286-0805, Japan.

Recently, one of promising piezoelectric materials for high-bit rates digital communication is $R_3GaGa_3(Ga,Si)O_{14}$ (*R*= rare earth) designated as langasite, which has larger electromechanical coupling factor than quartz and also has nearly the same temperature stability as quartz. The piezoelectric constant increases with the ionic radius of *R* [1]. In this study, the mechanism of the piezoelectricity was clarified based on the crystal structure.

The intensity data of langasite crystals grown by the Czochralski method were measured by the four circle X-ray diffractometer with rotating anode.

Crystal data of typical La-langasite are as follows; Sphere r=0.11mm, Trigonal, $P321$ (No.150), a=8.1539(3), c=5.0904(4) Å, Z=1, D_x=5.766Mgm^{-3}, λ=0.71073 Å, μ=228.44, 2θ<95°, final R=3.26%, wR=3.63%.

The atomic coordination of La- and Pr-langasite as follows:

Atoms:site	*x*: L/PGS	*y*: L/PGS	*z*: L/PGS
A:La/Pr:3e	.41872/.41793(4)	0	0
B:Ga,:1a	0	0	0
C:Ga2:3f	.76527/.76469(8)	0	1/2
D:Ga, Si:2d	1/3	2/3	.46780/.4654(3)
O:2d	1/3	2/3	.805/.802(2)
O:6g	.4649/.4693(6)	.3105/.3173(6)	.6833/.6885(9)
O:6g	.2229/.2250(7)	.0815/.0787(7)	.2356/.2381(9)

The initial atomic parmeters were quated from Mill *et al*.[2]. Those of Nd-langasite will also presented at the conference.

The piezoelectric constant of La-langasite was improved by the magunitude of the polarity of *R* ions in the *A*-site of $A_3BC_3D_2O_{14}$ general formula, which was produced by the size difference of the polyhedra of *R* ion.

P09.10.012 ELECTRON DENSITY IN $Rb(Cs)TiOAsO_4$ FROM SYNCHROTRON RADIATION DATA. J. Almgren[a], V.A. Streltsov[b] and J. Albertsson[a], [a]Department of Inorganic Chemistry, Chalmers University of Technology, Sweden, [b]Crystallography Centre, University of Western Australia, Australia (jean@inoc.chalmers.se).

High-flux synchrotron X-radiation has been used to study the electron density distribution in $MTiOAsO_4$ (M = Rb (RTA), Cs (CTA)) at room temperature and 100 K, respectively. The electron density maps for RTA resemble those obtained at 9.6 K [1]. However, the electron density near the Rb atoms is significantly diffuse and there are indications of splitting of the Rb positions at room temperature.

RTA and CTA belong to the $KTiOPO_4$ isomorphic family of compounds with strong non-linear optical properties. X-ray diffraction data at 9.6 K has shown significant shifts of the alkali atoms from their room temperature positions and dipole-like deformations of the electron density near the Ti atoms along the polar *c* axis. This indicates that these atoms contribute to the spontaneous polarization of the studied compounds. The electron density accumulates near the exceptionally short Ti - O bonds, which can be partly responsible for the non-linear optical properties.

The data were collected at BL14A, KEK Photon Factory, Tskuba, Japan. The RTA data set was measured at 295 K with λ = 0.75 Å. The total number of reflections were 47232 (44053 > $2\sigma(I)$), for a full sphere of data up to 2θ = 120°. A second data set

of half a sphere up to 2θ = 110° was collected at 100 K for a mixed RTA – CTA crystal, grown from a self-flux containing 60 % Rb and 40 % Cs. The structural results are similar to those reported in [2].

P09.10.013 $Na_4Co_3H_2(PO_4)_4{\cdot}8H_2O$ WITH A NEW STRUCTURE TYPE*. S.Y.Mao, Y.X.Huang, Z.B.Wei, J.X.Mi, Z.L.Huang and J.T.Zhao, College of Chemistry and Chemical Engineering, Xiamen University, Xiamen 361005, P.R. China

The recent work of Stucky et al.[1] concerning three-dimensional microporous alkali metal cobalt phosphates prompts us to report our new results. The title compound was synthesized by mild hydrothermal method in glass tubes under autogenous pressure and the crystal structure characterized by single crystal X-ray method. The structure was solved and refined using the SDP program package [2]. It possess a new type: monoclinic, mP106, $P2_1/c$, a = 7.3547(9)Å, b = 9.222(1)Å, c = 15.186(2)Å, β = 95.18(1), V = 1025.9(3)Å^3, Z = 2. It is characterized by stacked layers of corner sharing CoO_6 octahedra and CoO_5 trigonal bipyramids with PO_4 tetrahedra sandwiched by sodium cations and water molecules through hydrogen bonds. The tetrahedron around one of the P atoms is rather regular with average P-O distance of 1.539Å and angle of 109.5 but the other has some deformation caused by the OH group. Two Co atoms have different oxygen coordination : a regular octahedron (average distance of 2.094Å) and a deformed trigonal-bipyramid (to one of the epical O : 2.397Å; and to other O : range from 1.994 to 2.026Å) with the Co shifted out off the basil plane. Two Na atoms are octahedrally coordinated by oxygen atoms. The temperature dependence of the magnetic susceptibility follows the Curie-Weiss law and the effective magnetic moment per Co calculated is 4.69μ_B falling in the range of the expected values of 4.30 to 5.20 for the octahedrally coordinated high spin Co^{2+} ion [3].

This study was supported by the NNSF of China.

P09.10.014 STRUCTURE AND DEFECT STRUCTURE OF TEMPLATED SUBSTITUTED ALPO-5 R.B. Neder and K. Hradil, Institut f. Mineralogie, Am Hubland, 97074 Würzburg, Germany and A.N. Christensen, Department of Inorganic Chemistry, Aarhus University, 8000-Aarhus C, Denmark

We observed diffuse scattering by templated Mn substituded aluminum phosphate #5 micro-crystals. The sample displays diffuse streaks parallel to [001]* through Bragg reflections. Several broad bands of diffuse scattering are observed that are normal to [001]*. Near the hk0 plane broad bands roughly parallel to [001]* are observed. A unique feature, not known from any other sample, is two thin layers of diffuse intensity approximately normal to [001]*. The shape of these layers is roughly sinusoidal and the two layers intersect. The diffuse scattering is interpreted in terms of disorder of the templating molecule, triethylamine, which can assume different positions within the 1-D channels of the host structure.

Different space groups are reported for templated and calcined ALPO-5. We collected data for as grown Mn, Co and Zn substituted ALPO-5 micro-crystals (~ 110 x 20 x 20 μm) templated by triethylamine. The diffraction pattern of the Zn compound revealed split Bragg reflections, indicating orthorhombic symmetry. The Co and Mn compounds showed no indication of lower symmetry. Details of the structure refinement in space groups P6cc and Ccc2 will be reported. The refinements indicate hexagonal symmetry and an ordered Al and P distribution. Refined bond lengths and bond angles agree well with theoretical calculations.

P09.10.015 EXTENDED FRAMEWORKS STRUCTURES ENCAPSULATING FACIAL {MoO_3} CORE. Sue-Lein Wang, Kuei-Fang Hsu, Department of Chemistry, National Tsing Hua University, Hsinchu, Taiwan 300 ROC

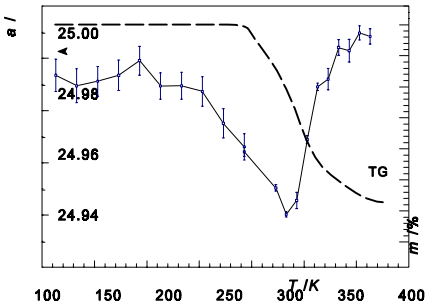
Three new alkaline-earth metal molybdenum(VI) arsenates, $Ba_3(MoO_3)_3(H_2O)(AsO_4)_2$ (1), $SrMoO_3HAsO_4.H_2O$ (2) and $Sr(MoO_2AsO_4)_2$ (3), have been prepared and structurally characterized by single-crystal X-ray diffraction and thermogravimetric analysis. Crystal data: 1, monoclinic, $P2_1/c$, a = 10.1814(2) Å, b = 17.5553(1) Å, c = 17.0799(1) Å, β = 90.349(1)°, V = 3052.75(7) Å^3, and Z = 8; 2, monoclinic, C2/c, a = 15.1927(11) Å, b = 10.2590(8) Å, c = 9.6550(7) Å, β = 121.877(1)°, V = 1277.9(3) Å^3, and Z = 8; 3, monoclinic, $P2_1/c$, a = 6.5904(3) Å, b = 6.8592(3) Å, c = 10.4472(5) Å, β = 92.106(2)°, V = 471.94(6) Å^3, and Z = 2. Crystal 1 adopts a novel open-framework structure which is composed of isolated MoO_6 and $Mo(H_2O)O_5$ octahedra linked by AsO_4 tetrahedra, resulting in intersecting tunnels where Ba^{2+} cations reside. Crystal 2 has a layer structure in which MoO_6 octahedra are corner-shared with $HAsO_4$ tetrahedra forming infinite sheets parallel to the (100) planes. The Sr^{2+} cations and water molecules are between the layers. Crystal 3 adopts a tunnel structure which is isotypic with the phosphates $A(MoO_2PO_4)_2$ (A = Ba, Pb). As a common feature, all of the MoO_6 octahedra possess three terminal O^{2-} ions in 1 and 2. They are the first extended structures encapsulating fac {MoO_3} units. Thermal analysis and powder X-ray diffraction studies revealed these units in 2 will progressively dissociate into cis {MoO_2} groups under heating, resulting in the structural transformation into 3. In this paper, the syntheses, crystal structures, thermogravimetric studies, and structural relationship are presented.

P09.10.016 SYNTHESIS AND CHARACTERIZATION OF NOVEL GALLIUM PHOSPHATES: $[Ga_4(C_{10}H_9N_2)_2(PO_4)(H_{0.5}PO_4)_2(HPO_4)_2(H_2PO_4)_2(H_2O)_2]$ AND $[Ga_5(OH)_2(C_{10}H_9N_2)(C_2O_4)(PO_4)_4]$. Kwang-Hwa Lii, Ching-Yeh Chen, Department of Chemistry, National Central University, Chungli, Taiwan ROC

The hydrothermal reactions of $Ga(NO_3)$, $4H_2O$, 4,4'-bypiridine, H_3PO_4, H_2O and butanol, and Ga_2O_3, 2-methylpiperazine, 4,4'-bipiridine, oxalic acid, H_3PO_4 and H_2O yield light brown crystals of $[Ga_4(C_{10}H_9N_2)_2(PO_4)(H_{0.5}PO_4)_2(HPO_4)_2(H_2PO_4)_2(H_2O)_2].?H_2O$ (1) and pale yellow crystals of $[Ga_5(OH)_2(C_{10}H_9N_2)(C_2O_4)(PO_4)_4].?2H2O$ (2), respectively, which have been characterized by single-crystal X-ray diffraction and solid state NMR spectroscopy. 1 crystallizes in the monoclinic space group C2/c with a = 26.4161(6), b = 8.0416(1), c = 20.3515(4) Å, b = 111.194(1)°, V = 4030.8(1) Å^3 and Z = 8. The compound has a 2-D layered structure in which the coordination environments around gallium are tetrahedral and octahedral; 4,4'-bipyridine is directly connected to the 6-coordinated Ga. This compound is unique in such a way that it is the first example in which four different types of phosphates, PO_4, $H_{0.5}PO_4$, HPO_4, and H_2PO_4 are present. 2 crystallizes in the monoclinic space group C2/c with a = 18.3430(2), b = 15.9372(4), c = 9.1019(2) Å, b = 90.867(1)°, V = 2660.5(1) Å^3 and Z = 4. The structure consists of GaO_4 tetrahedra and GaO_6 octahedra linked by phosphate and oxalate groups to form two dimensional sheets between which are the GaO_4N square pyramids, generating

tunnels in which the monoprotonated 4,4'-bipyridinium cations reside. 71Ga NMR shows a good correspondence between the fitted NMR parameters and the crystallographic data.

P09.10.017 THE ANTAGONISTIC THERMAL EXPANSION EFFECT IN ZEOLITES: A SINGLE CRYSTAL STUDY ON THE GUEST/HOST INTERACTIONS OF ZEOLITE NaX. J. Felsche and S. Riemann, Dept. Chemistry, University of Konstanz, Postfach M729, D-78457 Konstanz



The single crystal diffraction study and supplementary IR- and MAS-NMR spectroscopy at temperatures of 110-800 K confirm the antagonistic effect of thermal expansion in alumosilicate zeolites which have the sodalite cage in the 4,2-network structures in common [1]. The closing and subsequent opening feature around the inversion temperature of 340 K in zeolite NaX occurs during the continuous thermally induced desorption of H_2O molecules.The positions of the sodium atoms - detected by the diffraction methods - correspond to the minishing H_2O molecules in the super cage by moving into the center position of the sixfold rings at a critical H_2O-concentration. The positions of most of the guest atoms were not detectable by diffraction methods because of the dynamics in the nature of the hydrogen and the oxygen atoms, which show hoping frequences of 10^5 - 10^{15} cps at the interface to the tetrahedral host structure. The special key/lock mechanism between the sodium ions and the oxygen atoms of the 4,2-network shows an antagonistic character which is not well understood by the models sofar given for the thermal expansion in tetrahedral 3D-network structures. The big challenge to modern crystallography will be the deeper understanding of atoms in the 3D-space to time structure, which can only be ensured by using manifold analytical methods beyond diffraction.

P11.10.001 EFFECT OF Al DOPING ON STRUCTURAL CHARACTERISTICS AND SUPER-CONDUCTIVITY OF RE-123-TYPE SINGLE CRYSTALS. A.Zhilyaeva, L.Leonyuk, N.I.Leonyuk, Moscow State University, 119899 Moscow, Russia Bocelli Gabriele, Righi Lara Centro di Studio per la Strutturistica Diffrattometrica CNR, I-43100 Parma, Italy G.-J.Babonas, A.Reza Semiconductor Physics Institute, 2600 Vilnius, Lithuania R.Szymczak, H.Szymczak, M.Baran Institute of Physics, 02-668 Warsaw, Poland B.Sherriff University of Manitoba, Winnipeg, Canada

The series of RE-123-type (RE are rare earth elements) single crystals with the various Al-content has been grown by a self-flux method. The structural features were investigated directly by the XRD and NMR methods as well as by the analysis of Raman and optical spectra. The superconducting (SC) properties estimated by the measurements of magnetic susceptibility were correlated to the particular structure of the single crystals under consideration. The structural data for all compounds were analyzed in the space group *P4/mmm*.

	Composition	*a* (Å)	*c* (Å)	T_c (K)
1	$Sm(Ba_{1.8}Sm_{0.2})Cu_{2.63}Al_{0.37}O_{6.94}$	3.897(1)	11.580(2)	Nsc
2	$GdBa_2Cu_{2.70}Al_{0.30}O_{6.88}$	3.894(1)	11.702(3)	25
3	$Dy(Ba_{1.92}Dy_{0.08})Cu_{2.80}Al_{0.20}O_{6.49}$	3.877(1)	11.754(2)	50
4	$Gd(Ba_{1.98}Na_{0.02})Cu_{2.68}Al_{0.17}Na_{0.15}O_{6.55}$	3.887(1)	11.660(3)	35
5	$Sm(Ba_{1.86}Sm_{0.14})Cu_{2.64}Al_{0.36}O_{7.1}$	3.900(1)	11.638(3)	40

Taking into account the data obtained from NMR, Raman and optical spectroscopy, the structural model was proposed for the sample 1 which represents the tetragonal supercell with the Al and oxygen amount corresponding to these determined by XRD. According to the NMR data, Al is in a four-fold coordination in sample 1. The sample 5 contains the same Al-amount but in octahedral coordination and a slightly higher oxygen concentration. The sample 3 was assumed to possess the structure ortho-II. The occurrence of tweed structure is highly probable in the sample 2. The formation of a superstructure along the *c*-axis due to the ordered distribution of Al and Na cations in the alternating layers can be proposed for the sample 4.

The present studies have shown that the physical properties of the RE-123-type crystals are strongly dependent on the concentration and distribution of the Al-atoms.

P11.10.002 STRUCTURAL FEATURES OF SUPERCONDUCTING AND NON-SUPERCONDUCTING $[M_2Cu_2O_3]_5[CuO_2]_7$-TYPE (M=Sr, Ca, Bi) PHASES. L.Shvanskaya[1], L.Leonyuk[1], G.-J.Babonas[2], V.Maltsev[1], A.Reza[2] [1]Moscow State University, 119899 Moscow, Russia [2]Semiconductor Physics Institute, 2600 Vilnius, Lithuania

Superconducting (SC) and non-superconducting (NSC) single crystals of the $[M_2Cu_2O_3]_5[CuO_2]_7$-type (M=Sr, Ca, Bi) phases were grown from the solution in the melt Bi_2O_3-CuO [1].

	Composition	*a* (Å)	*b* (Å)	*c* (Å)
	$(Sr_{4.02}Ca_{5.84}Bi_{0.14})Cu_{15.84}O_{29.00}$	11.351(2)	12.809(3)	19.52(1)
I	$(Sr_{3.1}Ca_{5.9}Pb_{03}Bi_{0.4}Y_{0.3})Cu_{16.7}O_{29..0}$	11.316(2)	12.763(3)	19.49(1)
II	$(Sr_{4.42}Ca_{4.86}Bi_{0.05})Cu_{17.00}O_{29.00}$	11.349(7)	12.896(5)	19.49(3)
V	$(Sr_{6.07}Ca_{3.38}Pb_{0.07}Bi_{0.08}Y_{0.39})Cu_{16.73}O_{28.39}$	11.346(3)	12.996(3)	19.586(9)

The structural refinement was performed in the space group *F222* for SC phases I-III [1,2] and NSC phase IV. The most significant structural difference between SC and NSC phases was indicated in the local environment of Cu-atoms in the ladder-plane $M_2Cu_2O_3$. In the ladder plane the Cu-O squares were more distorted and the Cu-O distances were larger in the NSC crystals than in SC phases. However, the Cu-O distance for "apical" oxygen in NSC phase (2.57-2.79 Å) was significantly shorter than in SC phase (2.85-3.14 Å). Therefore the Cu in the ladder plane of NSC phase can be assumed to be in the pyramidal environment.

The present studies have shown the correlation between the structural and superconducting properties for the $[M_2Cu_2O_3]_5[CuO_2]_7$-type crystals similar to that [3] noted for Y-123-type compounds: an approach of apical oxygen to Cu atom in the ladder-type $M_2Cu_2O_3$ or ordinary CuO_2 plane leads to a suppression of superconductivity.

The difference between the optical spectra of SC and NSC $[M_2Cu_2O_3]_5[CuO_2]_7$-type compounds was also indicated and interpreted by the corresponding changes in the structure of two sublattices.

P11.10.003 ISOMORPHISM AND SUPERCONDUCTIVITY IN COMPLEX CUPRATES. L.Leonyuk[1], G.-J.Babonas[2], R.Szymczak[3], V.Maltsev[1] [1]Moscow State University, 119899 Moscow, Russia [2]Semiconductor Physics Institute, 2600 Vilnius, Lithuania [3]Institute of Physics, 02-668 Warsaw, Poland

A knowledge of stability region for solid solutions plays a dominant role in a search of new superconductors. In the present work recent data of isomorphic substitutions in complex cuprates are summarized and analyzed in order to estimate the possibility of the manifestation of superconductivity. At the substitution of basic elements in cuprates three main cases were considered

1. Complete isomorphism. A typical example is the substitution of Y by rare earth elements (RE) from the Y-group in the structural type Y-123 at which the superconductivity is maintained. As the superconductivity is related to the metastability of the structure [1], this case occurs quite rarely.

2. Absence of isomorphism: the substitution of basic elements leads to the formation of a new structural type. For example, the substitution of Y^{3+}+Ba^{2+} and Bi^{3+}+$(Ca,Sr)^{2+}$ for La^{3+}+Sr^{2+} in $(La,Sr)_2CuO_4$ resulted in the formation of Y-123 and Bi-2212-type compounds, respectively.

3. Limited isomorphism: *the structure as well as the superconducting properties *change at a substitution of basic elements.

3.1. The structural distortions occur at the substitutions as, e.g., in Y-123-type compounds doped by RE of the Ce-group and Al, Ca, Sr.

3.2. Formation of intergrowths due to narrow temperature-concentration crystallization regions of metastable superconducting phases (Bi-2212 at the substitution of Pb and RE for Bi and Ca, respectively [2].

3.3. Formation of inclusions of secondary phases due to the local ordering of cations (indication of T_c=110 K in the infinite-layer structure [3] and T_c=82 K in $(Sr,Ca)CuO_2$ [4]).

The formation of intergrowths and inclusions correlates with an increase of the T_c-values in superconducting compounds and occurrence of superconductivity in non-superconducting phases. It is reasonable to assume that the intergrowths and inclusions *illustrate* the metastability of the main phase**.

P11.10.004 STUDIES OF MOLYBDENUM DOPED POTASSIUM AND CESIUM HEXAGONAL TUNGSTEN BRONZE. A. Hussain , A. U. Monir, A. N. M. M. Rahman, Department of Chemistry, University of Dhaka, Dhaka - 1000, Bangladesh

Although it is more than a century since tungsten bronze, M_xWO_3, was first reported and even today these compounds have attracted much attention because of their interesting physical and chemical properties (1) .Recently, the effect of substitution of W atoms by other pentavalent or hexavalent transition metal atoms (2,3) and synthesis of mixed metal tungsten bronzes (4) have created interest among scientists.

Molybdenum doped potassium and cesium hexagonal tungsten bronzes, $M_{0.30}Mo_y W_{(1-y)} O_3$, where M = K and Cs and y = 0.05 -0.25 were prepared from homogeneous mixture of oxides in vacuum at 800°C . The products were then characterized by x-ray powder diffraction method. X-ray powder patterns of the samples were indexed as pure hexagonal tungsten bronze, HTB, type phase. The cell parameters of these Mo doped HTB were refined.

The cell parameters a and c in $K_{0.30}Mo_yW_{(1-y)}O_3$ decrease with increasing molybdenum content whereas the cell parameter a decreases while c increases with increasing molybdenum content in $Cs_{0.30}$ Mo_y $W_{(1-y)}$ O_3.

P11.10.005 CRYSTAL STRUCTURE AND LATTICE DYNAMICS OF RARE-EARTH HEXABORIDES. D. Yu. Chernyshov and V.A. Trounov, Condensed Matter Department of Petersburg Nuclear Physics Institute, Gatchina, 188360, RUSSIA, and M.B. Smirnov, Institute for Silicate Chemistry, St.-Petersburg, 199034, RUSSIA.

The structure properties of the series or rare-earth hexaborides (ReB_6, Re=La,Ce,Pr,Nd,Sm,Eu,Yb) have been studied by means of high-resolution neutron powder and single crystal x-ray diffraction methods. The established dependencies of structural parameters as well as the changes in the electronic structure and lattice dynamics of these compounds are discussed. The different dynamical properties (phonon frequencies, elastic constants and Debay-Waller factors) have been jointly treated in the lattice dynamics modeling. The important role of internal tension in dynamics of hexaborides has been proclaimed. This valence force field concept enables to explain the difference in dynamical properties of hexaborides with different rare-earth ion valences.

P11.10.007 ANOMALOUS COMPOSITION AND TEMPERATURE DEPENDENCE OF THE STRUCTURAL PARAMETERS FOR THE $NdBa_{2-x}Nd_xCu_3O_{7-\delta}$ SOLID SOLUTIONS. V.S. Mel'nikov, Institute of Geochemistry and Mineralogy, National Academy of Sciences of Ukraine, Kiev, Ukraine, Nedilko S.A. and Drozd V.A., Kiev Taras Shevchenko University, Ukraine.

$NdBa_2Cu_3O_7$ (Nd123) is a rare-earth analogue of high-T_c superconductor $YBa_2Cu_3O_7$ (Y123) but it has higher critical temperature of 93-97K. A difference between ionic radii of Ba^{2+} and Nd^{3+} is about 10% that leads to the $NdBa_{2-x}Nd_xCu_3O_{7\pm\delta}$ solid solutions formation at high temperature and to the phase separation at low temperature.

The samples $NdBa_{2-x}Nd_xCu_3O_{7-\delta}$ with x = 0-0.9 (x incrementation 0.05) have been synthesized by the citrate precursor method. To achieve the maximum oxygen saturation the samples on the final stage of the synthesis have been slowly cooling in the O_2-flow from 950 to 400°C. Single phase region in the $NdBa_{2-x}Nd_xCu_3O_{7-\delta}$ solid solutions was found to be x=0-0.9.

Temperature and composition dependencies of the structural parameters on the Nd/Ba ratio show some features which are not common for the Y123 phase. Tetragonal phase is formed at the 600-650°C for the stoichiometric samples (x = 0), but it is stable at room temperature if $x \geq 0.1$. In the temperature range of 400-1050°C there is a monotonous increase of c parameter with temperature ($dc/dT \approx 1.05 \cdot 10^{-4}$ Å/°C) for the

stoichiometric composition ($x = 0$), but if $x > 0.1$ the slope of $c(x)$ curve tends zero ($dc/dT \rightarrow 0$). For the compositions with $x > 0.15$ the parameter c does not depend on T.

Composition (x) dependence of the crystal lattice parameters show anomaly caused by the heterogenization of the solid solutions. Linear decrease a and c parameters with x growth is changed by "plateau" region ($da,c/dT \approx 0$) at $0.3 \leq x \leq 0.5$. Results of XRD study is in a good agreement with thin lamella, coherent conjugate structure formation during solid solutions decomposition.

Superexcess oxygen content in the $NdBa_{2-x}Nd_xCu_3O_{7+\delta}$, type of it distribution through the crystal structure and the features of heterogeneous structure have strong affect on the critical parameters (T_c, J_c) of the superconducting materials on the bases of Y123.

P11.10.008 NEW GADOLINIUM POLYSULFIDE CELL: 12-FOLD PbFCl-TYPE SUPERSTRUCTURE. I.A. Matveenko and G.M. Kuz'micheva, Department of Solid State Physics and Chemistry, Lomonosov State Academy of Fine Chemical Technology, Vernadsky pr. 86, Moscow 117571, Russia, and V.B. Rybakov, M. V. Lomonosov State University, Vorobyevy gory, Moscow 119899, Russia and I.G. Vasil'eva, RAS Insitute of Inorganic Chemistry, Acad. Lavrent'ev prosp. 3, Novosibirsk 90, Russia.

PbFCl structure type is basal for all the rare-earth (RE) polychalcogenides with general composition $[Ln^{3+}X^{2-}](X^{2-}_2)_{(x-0.5v)}(X)_{0.5-x}[\ ]_v\in_y$ ($0<x\leq0.5$, $y=0.5-x$) ([ ]-vacancy, $\in$ - missing position compared with PbFCl structure). Depending on Ln sort and deficiency rate anion vacancies can order in different directions (<100><110><210>, etc.) to form PbFCl (a_0, c_0) superstructures. Structural investigation of $GdS_{1.85}$ single crystal synthesised by solution-in-melt technique has been carried out. The crystal had a plate-like form and dark-red colour. Cell parameters found are unusually long for an inorganic substance: a = 46.651 (13), b = 46.651 (13), c = 15.825 (5)Å. It led us to suggest 12-fold a and b lattice parameters (m=n=12) and 2-fold c parameter (p=2) enlargement compare with PbFCl unit cell. This kind of subcells stacking should result in body-centred I-cell. Considering systematic extinction among reflections obtained and as a result of structural modelling we suggested I 4/mmm or I $\bar{4}$m2 space group with 96 Gd and 672 S atoms in unit cell. The structural features of this phase are under further investigation and discussion.

P11.10.009 LATTICE DISTORTION IN HIGH-T_c SUPECONDUCTOR $La_{2-x}Sr_xCuO_4$, H. Yamada, Y. Soejima, A. Okazaki, Department of Physics, Kyushu University, Fukuoka 812-8581, Japan, I Tanaka and H. Kojima, Institute of Inorganic Synthesis, Yamanashi University, Kofu 400-0021, Japan

High-resolution X-ray diffraction measurements of the lattice constants of $La_{2-x}Sr_xCuO_4$ (x=0.143) have been made at temperatures down to 17 K. Below the structural phase transition at 185 K, the lattice distortion of the orthorhombic cell indicates the condensation of not only the buckling mode but also the scissors mode of phonons. At temperatures below the superconducting transition at 35 K, it is found that the lattice distortion is frozen so that the thermal expansion coefficients of the lattice constants a and b are almost temperature independent. On the other hand, the sign of the thermal expansion coefficient of c changes, on cooling, from positive to negative at the transition. In the recent neutron diffraction experiments made by the present authors, the intensity, though extremely weak, has been observed at the X point in Brillouin zone in both the normal and superconducting phases. The intensity is about one tenth of that at the M point corresponding to the condensation of the buckling. The results suggest that a reinvestigation of the lattice distortion in both the low-temperature orthorhombic phase and the superconducting phase is necessary.

P11.10.010 SECONDARY CHEMICAL BONDS AS CONDUCTION PATH OF PHOTO-SEMICONDUCTING ELECTRONS: A CASE STUDY. F. Liebau, Institut für Geowissenschaften der Universität Kiel, D-24098 Kiel, Deutschland

To derive an insight into the conduction mechanism of a semiconductor, it is common practice to calculate its electronic band structure. Here it is shown that, under favourable conditions, the conduction paths of electrons can be deduced from the crystal structure with the help of careful bond-valence calculations. – At present eight cetineite-type phases of composition

$\mathbf{A}_6[Sb(2,3)_{12}O_{18}][Sb(1)\mathbf{X}_3]_2[\mathbf{D}_x(H_2O, OH, O)_{6-y}]$ with **A** = Na, K, Rb, Sr, Ba; **X** = S^{2-}, Se^{2-}; **D** = Na, Sb^{3+}, C are known [1] and their crystal structures have been refined. Four of these phases were found to be photo-semiconducting. Their optical band gaps were measured and their band structures were calculated [2]. Strong covalent bonds between trivalent Sb(2, 3) and oxygen atoms produce electroneutral $[Sb_{12}O_{18}]$ tubes which are held together by strong ionic bonds between the **A** cations within the tubes and the $\mathbf{X}^{2-}$ ions of the $[Sb(1)\mathbf{X}_3]$ groups. Results of bond-valence calculations indicate that:

bond-valence sums, ^{eff}V, of Sb(1) vary strongly (3.27-3.99 v.u.) and are considerably larger than the formal valence of antimony,+3;

the ^{eff}V-values of Sb(2) and Sb(3) vary only between 3.00 and 3.31 v.u.;

in addition to the strong primary bonds Sb(1)–**X**, Sb(2)–O, **A**–O, and **A**–**X**, each Sb(3) atom has two weak secondary bonds Sb(3)–**X** of up to 0.23 v.u., which form chains spiraling along [001]. Calculated band gaps are correlated with the sums of the valences of these secondary bonds.

Conclusions: 1) The strongly stereoactive Sb(1) atoms provide the electrons which then use the weak secondary Sb(3)—**X** bonds as conduction paths.

With necessary carefulness, conclusions about conduction mechanisms of semicoductors can be drawn from crystal structure with the aid of bond-valence calculations.

[1] W. Wang & F. Liebau (1998). Eur. J. Solid State Inorg. Chem. **35**, 27.

P11.10.011 NEUTRON POWDER DIFFRACTION STUDY OF $Tb_{2-x}Ba_{2+x}Ti_2Cu_{2+y}O_{11}$. J.-E. Jørgensen, Department of Chemistry, University of Århus, DK-8000 Århus C, Denmark.

The $Ln_2Ba_2Cu_2Ti_2O_{11}$ compounds are structurally related to many of the high temperature superconducting cuprates but they have no yet been made superconducting. Structurally they are quadrupled perovskite containing a CuO_2-Ln-CuO_2 sandwich similar to what is found in many high T_c compounds. The $Ln_2Ba_2Cu_2Ti_2O_{11}$ compounds have been prepared for Ln= Nd, Sm, Eu and Tb. We have prepared samples of composition : $Tb_{1.8}Ba_{2.2}Ti_2Cu_2O_{11}$, $Tb_{1.8}Ba_{2.2}Ti_2Cu_{2.1}O_{11}$ and $Tb_{1.8}Ba_{2.2}Ti_2Cu_{2.1}O_{11}$ and neutron powder diffraction data were collected at room temperature and Rietveld refinements were performed with the GSAS program package. The $Tb_2Ba_2Ti_2Cu_2O_{11}$ compounds are tetragonal with space group P4/mmm (a ≈ 3.89 and c ≈ 15.70 Å) and the atomic positions in the fully ordered structure are:

Tb(1) 1c (1/2 1/2 0), Tb(2) 1d (1/2 1/2 1/2), Ba 2h (1/2 1/2 z_{Ba}), Cu 2g (0 0 z_{Cu}), Ti 2g (0 0 z_{Ti}), O(1) 1b (0 0 1/2), O(2) 4i (0 1/2 z_2), O(3) 2g (0 0 z_2), O(4) 4i (0 1/2 z_4)

In addition to the positional parameters site occupation factors for the cations were refined and it was found that cation disorder is present in all three samples. Cu and Ti were found to be distributed over the 2g sites while Tb and Ba are distributed over the 1d and 2h sites. The 1c site, which is located between the CuO_2 layers, was found to contain Tb only. Our study also shows that the excess Cu in $Tb_{1.8}Ba_{2.2}Ti_2Cu_{2.1}O_{11}$ ensures that the Cu site in the CuO_2 layers are 100% occupied by Cu. Excess copper is therefore presumably a necessity for making these compounds superconducting although the studied samples were non-superconducting. The results for the $Tb_{2-x}Ba_{2+x}Ti_2Cu_{2+y}O_{11}$ compounds will be compared with our earlier study of the the $Nd_{2-x}Ba_{2+x}Ti_2Cu_{2+y}O_{11}$ compounds. [1]

P11.10.012 STRUCTURAL CHANGE IN $YBa_2Cu_3O_x$ CRYSTALS BY H_2O ABSORPTION. S. Edo, Department of Mechanical System Technology, Hokkaido Polytechnic College, Zenibako 3-190, Otaru 047-02, Japan and T. Takama, Department of Applied Physics, Faculty of Engineering, Hokkaido University, Kita-ku, Sapporo 060, Japan.

Structural change induced by absorption of H_2O molecules of the high-T_c superconductor $YBa_2Cu_3O_x$ has been investigated by X-ray diffraction measurement. The single crystals were prepared by the self-flux method using a mixture of $BaCO_3$ and CuO powders as a flux. They showed a shape of rectangular prism. They were annealed at 725 °C in air and subsequently quenched into liquid nitrogen to obtain oxygen content x of ~6.4. The diffraction profiles were measured along given directions in the reciprocal space at room temperature using a full-circle goniometer and Cu Kα radiatoin. The profile measured along c* indicated that the lattice parameter c increased to 13.61 Å. This means that the crystal is elongated by ~16% along the c-axis owing to H2O absorption. Superlattice reflections were clearly observed at the positions of (l+l/2)c*. In contrast to the c-axis, changes in a and b were relatively small (a=3.87 Å and b=3.88 Å). Setting angles of the goniometer suggested that a, b, and c are perpendicular to each other. From the experimental facts, it is revealed that the compound transformed to tetragonal-like structure with a superlattice along the c-axis by the absorption. The profile along c* showed broad peaks, while the profiles along a* and b* showed relatively sharp peaks. It is thought that inhomogeneous strain was introduced into the sample by the large elongation along the c-axis and broadened the profiles along c*. The structural change will be discussed in comparison with that observed in the polycrystals.

P11.10.013 STRUCTURAL INVESTIGATION OF SnO_2 DOPED WITH ANTIMONY. E. Tkalcec and C. Goebbert, Institut für Neue Materialien, 66123 Saarbrücken, Germany and B. Grzeta, Rudjer Boskovic Institute, POB 1016, 10001 Zagreb, Croatia.

Tin oxide, SnO_2, has been widely used as a conductor in electronic devices. Dopands, such as antimony, incorporated into SnO_2 thin films cause the change in resistivity of such films. The resistivity decreases for lightly-doped SnO_2, and increases for heavily-doped SnO_2 [1]. The mechanism of this phenomenon is not well understood yet. The aim of the present work is to examine the influence of Sb dopand on the structure of SnO_2. A series of Sb-doped SnO_2 samples, with doping level of 0, 2.9, 5.9 and 12.3 at% Sb, was hydrothermally prepared and characterized by X-ray powder diffraction. The samples were tetragonal, space group $P4_2/mnm$ and isostructural with TiO_2(rutile). Both *a* and *c* unit-cell parameters increased as the Sb doping content increased, but the ratio *c*/*a* remained constant at the value characteristic for SnO_2. Diffraction lines were broadened, indicating nanosized crystallites in the samples. The lines of pure SnO_2 showed the greatest broadening. As the amount of dopand increased the broadening decreased. Also, the lines *hk*0 were systematically broader than the lines *hk*1, *hk*2 and *hk*3 for all samples as a consequence of elongation of the crystallites along the *c*-axis. The structure of samples containing 5.9 and 12.3 at% Sb was refined by the Rietveld method [2]. Crystal structure results indicated that both Sn^{3+} and Sb^{5+} were substituted for Sn^{4+} in the non-stoichiometric rutile-type phase with oxygen deficiency.

P11.10.014 MAGNETIC ORDER AND STRUCTURE INVESTIGATIONS OF RB2C2 RARE EARTH BOROCARBIDES. J. van Duijn, J.P. Attfield [1], K. Suzuki [2], [1] Dept. of Chemistry, University of Cambridge, Lensfield Road, Cambridge CB2 1EW, England, [2] Graduate school of Enginering, Yokohama National University, 79-5 Tokiwadai, Hodogaya-ku, Yokohama 240-8501, Japan

The rare earth diborodicarbides (RB_2C_2) have been known for some years, but until now their low temperature properties have not been explored. They have a simple tetragonal structure consisting of extended planar boron-carbon sheets of linked four- and eight-membered rings with the R atoms between the eight membered rings of successive layers. Previous room temperature X-ray studies indicate that the eight-membered rings consist of alternating B_2 and C_2 pairs [1,2], although band structure calculations indicate that the alternation of individual B and C atoms is more stable [3]. Magnetisation measurements show that the RB_2C_2 compounds order antiferromagnetically, perhaps helimagnetically in some cases, with ordering temperatures ranging from 6.5 K for CeB_2C_2 to 23.5 K for TbB_2C_2. Neutron powder diffraction data have been collected from several ofthese compounds using diffractometer D2B at ILL, Grenoble. The samples were enriched with boron-11 to reduce absorption, enabling crystal and magnetic structures to be determined.

P11.10.015 CRYSTAL STRUCTURE SOLUTION OF COMPOUND SEMICONDUCTOR $Cu_3In_7Se_{12}$ FROM COMBINED CONVERGENT BEAM ELECTRON DIFFRACTION, X-RAY POWDER DIFFRACTION, AND X-RAY ABSORPTION FINE STRUCTURE DATA. C.-H. Chang and T.J. Anderson, Department of Chemical Engineering, University of Florida, Gainesville, FL 32611, E. Fodran, Department of Materials Science and Engineering, University of Florida, Gainesville, FL 32611, E.A. Payzant, High Temperature Materials Laboratory, Oak Ridge National Laboratory, Oak Ridge, TN 37831-6064, R. DURAN, Department of Chemistry, University of Florida, Gainesville, FL 32611

Great efforts are being devoted to the development of polycrystalline thin film solar cells based on chalcopyrite $CuInSe_2$ and related compounds. The observed junction between $CuInSe_2$ and the In-rich compounds (*e.g.* $Cu_2In_4Se_7$, $Cu_3In_7Se_{12}$, and $CuIn_3Se_5$) appears to play an important role in the photovoltaic process. In general the structure of these compounds belong to

defect tetrahedral structures. They can be described as normal tetrahedral structures with a certain fixed number of unoccupied structure sites. In spite of many efforts have been devoted to investigate the structure for these compounds. There remain many inconsistencies in the reported structure solutions. The reasons for these inconsistencies are associated with the difficulty in assigning the space group based on X-ray diffraction data, and disordering in the cation sublattice.

Convergent Beam Electron Diffraction was carried out to obtain the symmetry information for compound semiconductor $Cu_3In_7Se_{12}$. The resulted space group and unit cell parameters were used in the analysis of X-ray diffraction powder data. The local structure data, which were derived from X-ray Absorption Fine Structure measurements on Cu_K and Se_K edge, were used as building blocks for assigning atomic positions. Rietveld refinement was performed to obtain the final structure solution.

P11.10.016 VARIATION OF Cu IN Bi-BASED HIGH-T_C SUPERCONDUCTORS. Muhammad Anis-Ur-Rehman Thermal Physics Laboratory, Department Of Physics, Quaid-I-Azam University, Islamabad, Pakistan.

Samples with nominal composition $Bi_{1.6}Pb_{0.4}Sr_2Ca_2Cu_{2+X}O_Y$ and $Bi_{1.6}Pb_{0.2+X}Sr_2Ca_2Cu_4O_Y$ were prepared by the solid state reaction method. Resistivity, ac magnetic susceptibility and X-ray diffraction studies were done. Sample with X=2.0 in the first composition showed T_c at 127 but the recipe was often not reproducible. Increase in Cu ratio (i.e. x=2.5) did not show any dramatically high Tc. So the role of Pb was studied. Increase in Pb ratio showed the adverse effects. Decreasing Pb improved the results. Samples with nominal composition $Bi_{1.6}Pb_{0.4}Sr_2Ca_2Cu_{2+X}O_Y$ (x=2.5) and $Bi_{1.6}Pb_{0.2+X}Sr_2Ca_2Cu_4O_Y$ (x=0.0) showed somewhat similar behaviour. It means that the compositions are not only sensitive to ratio of Cu but also to that of Pb.

Properties of the samples also depend on the thermal process. Step sintering was found to be more favourable towards magnetic properties of the samples. Prolonged sintering makes the systems more metallic like and smooth variation in resistivity with temperature, is observed. After final sintering XRD patterns were obtained. The superconducting phase identified by XRD analysis is the high-Tc phase in all the four samples, similar results of resistivity and susceptibility measurements were observed.

P11.10.017 STRUCTURAL RELATIONSHIPS PRESENT IN THE $CuFeX_2$ (X=S, Se, and Te) FAMILY OF SEMICONDUCTORS. J.M. Delgado, R.A. Guevara, E. Roque-Infante, Laboratorio Nacional de Difracción de Rayos-X, Facultad de Ciencias, Universidad de Los Andes, Mérida 5101, Venezuela.

It would be expected that the three ABX_2 copper iron chalcogenides would exhibit the chalcopyrite type of structure that is typical of the I III VI_2 semiconducting compounds. But, it is surprising that only one of them, $CuFeS_2$, displays such a structure which, coincidentally, was named after the mineral with this particular chemical composition.

In this contribution, a comparison of the characteristic features of the structure of $CuFeS_2$ and $CuFeSe_2$ as well as the structural aspects of the disordered structure recently reported for $CuFeTe_2$ will be examined [space group *P4/nmm* with *a*=3.989(1) and *c*=6.094(3)Å]. It must be mentioned that no report of its eventual ordered structure has been found in the literature. Several attempts to prepare X-ray quality single crystals of this material have failed to produce the expected results so far. However, good single crystals of Cu_3FeTe_3, a previously unknown material have been obtained in the batchs intended to produce $CuFeTe_2$. During this investigation it has been determined that Cu_3FeTe_3 crystallizes in space group *Cmma* with *a*=5.656(1), *b*=17.478(4), and *c*=6.073(2)Å and represents an ordered superstructure derived from the disordered structure reported for $CuFeTe_2$. The relation between the orthorhombic unit cell obtained for Cu_3FeTe_3 and the tetragonal unit cell reported for $CuFeTe_2$ is given by $[\mathbf{a},\mathbf{b},\mathbf{c}]_O = [1,-1,0/3,3,0/0,0,1][\mathbf{a}_1,\mathbf{a}_2,\mathbf{c}]_T$.

This work was supported by CONICIT, grant LAB-97000821 which established the Laboratorio Nacional de Difracción de Rayos-X and by CDCHT-ULA, grant C-727-95-08-A in Venezuela. Part of this work made use of the MRL-UCSB Central Facilities, supported by the National Science Foundation under Award No. DMR96-32716 in the USA.

P11.10.018 ROLLING AND RECRYSTALLIZATION TEXTURES IN PURE SILVER SHEET. J. Palacios-Gómez, H. Mendoza-León and J. G. Cabañas-Moreno, H. A. Calderón, Instituto Politécnico Nacional, Apdo. Postal 75-373, 07300 México, D.F., México, and A. de Ita, Universidad Autónoma Metropolitana, México D.F., and C. Falcony-Guajardo, CINVESTAV-IPN, México, D.F.

One of the forms in which high temperature superconductors are intended to be of practical use is as films on strongly textured metal substrates [1]. Silver represents one of a handful of metals possessing attractive features as a metal substrate for this purpose [1]. In particular, there exists a very good match between the (100) atomic arrangements in silver and the corresponding arrangements on the basal plane of some ceramic superconductors, like the ytrium-base and thallium-base ceramic oxides [1].

A preferred orientation of (100) planes parallel to the rolling plane in some fcc metals is found in the so-called cubic recrystallization texture, namely, the (100)<001>texture. This texture is usually developed by the recrystallization of material originally having a strong copper-type rolling texture, which in turn makes necessary the application of large rolling reductions. Pure silver requires rolling at temperatures higher than 150-200°C to develop the copper-type texture; this, however, also promotes dynamic and/or static recrystallization of silver, which prevents the generation of a strong rolling texture.

Experimente to determine the effects of temperature of deformation, as well as time and temperature of annealing on the resulting textures of nominally 99.9 and 99.99% silver sheet have been performed. X-ray diffraction studies were used to characterize the textures produced by the different rolling-annealing treatments.

As expected, heavy rolling of silver at room temperature produced the brass-type rolling texture, namely, (110)<1-12>. The changes resulting from annealing the cold-rolled material at temperatures between 400 and 900°C were quite complex; in general terms, a significant cube component appeared at the lower annealing temperatures - coexisting with a brass-type component, but the former was found to diminish in intensity as the annealing temperature was increased. Basically, random crystallite orientations were obtained with annealing temperatures of 800°C (and higher). Additional results concerning texture formation will also be presented.

P11.10.019 HRTEM ANALYSIS OF NEW OXYCARBONATE SUPERCONDUCTORS DOPED WITH NITROGEN. Y. Matsui[1], Y. Ishida[1,2], Y. Anan[1,2], J. Hatano[2], N. D.Zhigadlo[1], A. T.Matveev[1], E. Takayama-Muromachi[1], [1] National Institute for Research in Inorganic Materials, 1-1 Namiki, Tsukuba, Ibaraki 305-0044, Japan, [2] Faculty of Industrial Science and Technology, Science University of Tokyo, 2641 Yamazaki, Noda, Chiba 278-8510, Japan

Plenty of new oxide superconductors have successfully been prepared by high-pressure synthesis technique, and their crystal

structures have been analyzed by high-resolution transmission electron microscopy (HRTEM). Especially, some of new oxycarbonate superconductors, containing CO_3 groups, are revealed to have unique superstructures due to ordered arrangements of CO_3 groups in the charge-reservoir blocks[1]. In the present study, we performed HRTEM investigation on the structural features of a new series of nitrogen-doped oxycarbonate superconductors, prepared in a Sr-Ca-Cu-N-C-O system under high-pressure.

Series of homologous compounds with nominal compositions of $(Cu,N,C)Sr_2Ca_{n-1}Cu_nO_y$ were synthesized by solid state reactions of CuO (99.9%), $Sr(NO_3)_2$ (99.9%), $SrCuO_2$, SrO_2, Ca_2CuO_3, $SrCuO_3$ (99.9%) and $CaCuO_3$ (99.9%), under high-pressure of 5-6GPa at 1200-1375 C, for 1-6 hours. TEM specimens were prepared by the crushing method and then examined by Hitachi H-1500 type HRTEM which is developed at NIRIM[2]. In this study, all of the HRTEM observations were made by 800kV acceleration voltage.

Four compounds, with n-values from 3 to 6, were obtained as stable phases in the present system. All the four phases showed superconductivity, with the highest T_c=113K for $(Cu,N,C)Sr_2Ca_3Cu_4O_y$ (n=4). Possibilities of superstructures due to ordered arrangements of Cu and (CO_3 + NO_3) are examined by electron diffraction and HRTEM method. Ordered arrangements of Cu and (CO_3 + NO_3) are observed in both n=3 and n=4 phases. Superstructure with 4-times periodicity a_S=4a, due to -Cu-X-X-X-Cu-X-X-X-Cu- (X=CO_3 or NO_3) in the charge-reservoir blocks, are observed only in both n=3 phase. While the superstructure with twice periodicity a_S=2a due to -Cu-X-Cu-X-Cu- (X=CO_3 or NO_3) sequence was observed in both n=3 and n=4 phases. On the other hand, no evidence of superstructures have been detected in both n=5 and n=6 phases, and it is considered that Cu and CO_3 (or NO_3) are almost randomly distributed in the charge-reservoir blocks.

1) Y.Matsui: J.Electron Microsc. 46(2) (1997) 135-150.

P11.10.020 STRUCTURE INVESTIGATIONS OF DOPED Hg-CONTAINING SUPERCONDUCTING OXIDES. I. Bryntse and M. Valldor, Dept. of Inorganic Chemistry, Arrhenius Laboratory, Stockholm University, S-10691 Stockholm, Sweden.

The structures of the superconducting cuprates $HgBa_2CaCu_2O_{6+\delta}$ "1212" and $(Hg,Tl)_2Ba_2Ca_1Cu_2O_{8+\delta}$ "2212" possess a larger Ba-site where Ba^{2+} is co-ordinating approximately 9 oxygen atoms and a smaller Ca^{2+}-site surrounded by 8 nearest oxygens. We have investigated how the unit cell, structure details and superconducting properties are affected by dopants or replacements at these positions in particular.

At first, the Ba-site was attempted to be completely replaced by the smaller isovalent Sr^{2+} in the 2212 type phase. It was found by single crystal analysis that Sr and Ca were mixed at both the sites described above, with an excess of Sr at the larger site. Structural data of the phases with starting compositions $(Hg,Tl)_2Sr_2CaCu_2O_{8+\delta}$ and $(Hg,Tl)_2(BaSr)_2(CaSr)Cu_2O_{8+\delta}$, will be presented and compared to the structure of $(Hg,Tl)_2Ba_2Ca_1Cu_2O_{8+\delta}$. Superconducting transitions were determined by magnetic susceptibility to 45-100 K, depending upon the degree of Sr substitution.

Then, Ba was replaced by the trivalent cation La^{3+} in the 1212 type phase. 20% of lanthanum at the Ba-site was found to almost completely destroy the superconductivity. The unit cell parameters were refined to *a*=3.899(2) Å and *c*=12.423(9) Å, indicating that the metal-oxygen distances in the *ab*-plane increase slightly and the apical distances shrink significantly compared to undoped Hg-1212, which usually has the cellparameters *a*≈3.864 Å and *c*≈12.71 Å. Structural data obtained from a Rietveld refinement will be presented as well as an electron microscopy study.

At last, the synthesis problems and hopefully results of substituting a mono-valent cation for Ba will be discussed.

P11.10.021 STUDY OF ATOMIC DISTRIBUTION FUNCTIONS IN PEROVSKITE CRYSTALS. D.A. Kovtun, A.P. Kovtun and M.F. Kupriyanov, Department of Physics, Rostov State University, 5 Zorge Str., 344090 Rostov-on-Don, Russia.

In the work we investigated the atomic distribution functions with the X-ray structure amplitudes from single-crystal of $SrTiO_3$ at various temperatures. We considered two atomic distributions: conventional Gauss distribution and S-distribution that implies the uniform disorder of the atom over a sphere. The structure was refined by least-squares refinement procedure using derived analytical expression of the scattering form-factors.

We obtained that the atomic distribution function of titanium atom was principally of S-type. The radius of the sphere was observed to be practically independent of the temperature.

The work presents the theory that explains the atomic distributions observed in perovskite crystals. Moreover, we show the explanations of the results published earlier in a great deal of papers, according to which the heavy atoms have the larger temperature parameters than those of the light atoms in the structure.

P11.10.022 EFFECTS OF SHORT - ORDERING IN PMN CRYSTALS. Alla R. Lebedinskaya, Faculty of Physics and Chemistry, Azov - BlackSea State Agro Engeniheering Academy, Zernograd, Rostov Region, 347720, Russia, Mikhail F. Kupriyanov, Faculty of Physics, Rostov State University, Rostov on Don, 344090, Russia

The crystal of complex compound $PbMg_{1/3}Nb_{2/3}O_3$ at room temperature has a cubic perovskite structure with the lattice constant a=4.034 Å. and exhibits the properties of ferroelectric - relaxors in a broad interval of temperatures.The microscopic mechanism of the structural transformations in relaxor ferroelectrics is not clear yet. Earlier is established, that for low temperatures and for applying the electric constant field the PMN has a rhombohedral phase. It was found that the lead ions are shifted from the special position (0,0,0) at the temperatures low then average Curie temperature 230 K.

At the same time, on data of the electrongraphic analysis the effect of ordering of atoms of a different grade in the same sublattice of a type 1:1 is established, that will be poorly agreed with chemical PMN structure : Mg/Nb = 1:2.

With the purpose of clearing up of a real of these effects by us are analysed the results of a X-ray diffraction of monocrystal $PbMg_{1/3}Nb_{2/3}O_3$ for temperatures 103K, 183K and 293 K and proposed the model of PMN behaviour at two low temperatures.

From the analysis of reflections is obvious, that the reflexes with nonzero significance L (type 00L) hardly are overestimated on a comparison with reflexes for zero significance L. It was determined the factors of Debay - Waller of atoms for temperatures of 103, 183 and 293 K. It was determined, that for these temperatures B (Pb) > B (O) > B (Mg/Nb). In our opinion, the biggest Debay - Waller factor for atom of lead is explained by not only the thermal displacements from an ideal item of this atoms in PMN crystals.

The obtained maps of distribution of electronic densities allow to assume the disordered character of displacements from an ideal item of atoms of lead mainly in a plane {ZX} and the ordering of Mg/Nb ions in that plane . The order of a Pb displacement does not exceed 0.28 Å. In the present work we determined also the shifts of O^{2-} ions at this temperatures . We supposed that this shifts depend from the behaviour of the lead ions and from effect of Mg/Nb ordering.

P11.10.023 INFLUENCE OF COMPOSITION RELATION MG:NB IN PMN ON ITS PROPERTIES. Alla R. Lebedinskaya, Faculty of Physics and Chemistry, Azov - BlackSea State Agro Engenireering Academy, Zernograd, Rostov Region, 347720, Russia, Mikhail F. Kupriyanov, Faculty of Physics, Rostov State University, Rostov on Don, 344090, Russia, Richard Skulskiy, Silesian University, Katowice, Poland

The purpose of this work is the clearing of a reality of ordering effects in a pseudo-binary system of solid solutions (1-x)$PbMg_{1/3}Nb_{2/3}O_3$ -(x)$PbMg_{1/2}Nb_{1/2}O_{2.75}$.

The compositions with x = 0; 0.1; 0.2;..1.0 were prepared on usual technology of the solid - phase reactions.

The Debey- Waller factors of atoms are determined with the using of integrated intensities of diffractional reflections from these system on diffractometer CAD-4 (MoK_α - the radiation, $Sin\theta/\lambda < 1.01$ Å^{-1}).

First, the crystal of complex compound $PbMg_{1/3}Nb_{2/3}O_3$ at room temperature has a cubic disodered perovskite structure with the lattice constant a=4.034 Å. Then, for the system of (1-x) *$PbMg_{1/3}Nb_{2/3}O_3$-(x) *$PbMg_{1/2}Nb_{1/2}O_{2.75}$ lattice constants, dielectric constants, spontaneous polarization and thermal expansion were measured as a function of temperature for varying x.

It is established, that in the given system the continuous solid solutions will be depended on a character of modifications of parameters of a lattice. Dielectric measurements of ceramic have shown , that relaxor properties are definited a diffusion of ferroelectric phase transition, depending from the structure of a solid solution, i.e. parameter x.

The correlations beween structure evolution and dielectric properties in lead magnoniobate are discussed.

P11.10.024 NEW PHASES IN La-Cu-O AND (La,Ba)-Cu-O SYSTEMS: SYNTHESIS, COMPOSITION, STRUCTURES, PECULIARITIES. V.V. Luparev and G.M. Kuz'micheva, Department of Solid State Physics and Chemistry, Lomonosov State Academy of Fine Chemical Technology, Vernadsky pr. 86, Moscow 117571, Russia, and E.P. Khlybov, L.F. Vereschagin Institute for High Pressure RAS, Troitsk, Russia, and A.V. Mitin, P.L. Kapitsa Institute for Physical Problems RAS, Kosygina ul. 2, Moscow 117973, Russia.

We applied high pressure-high temperature technique to synthesise cubic perovskite and prepared phases with rhombohedral lattice, which represent a small distortion of the perovskite cubic cell: a_R≈3.8612Å, α_R≈90.69° (I, Sp.gr. R $\bar{3}$m, p=3.5 GPa, t=1000°C, τ=10 min) and a_R≈3.8597Å, α_R≈90.63°(II, p=4 GPa, t=1250°C, τ=10 min), moreover we revealed such type of distortion for the first time. We carried out the Rietveld refinement of crystal structures by DBWS-9411 program with x-ray powder diffraction data. It was found that the most probable compositions are $La_{0.99(1)}CuO_{3.00(3)}$ (I, Formal valence FV Cu~3.00) and $La_{0.98(1)}CuO_{2.94(6)}$ (II, FV Cu~2.94). Phase with tetragonal perovskite-like structure $La_{0.99(1)}CuO_{2.90(2)}$ (a=3.8183(1), c=3.9782(1)Å) was formed from rhombohedral one (I) under annealing in Ar atmosphere (t=280°C, τ=40 min). From initial composition $(La_{1-x}Ba_x)CuO_{3-\delta}$ we prepared samples, which distinguish in contents of cubic and superstructure ($a \approx a_0$, $c \approx 3a_0$) phases depending on conditions of synthesis (p=5-7 GPa, t=800-1100°C or without high-pressure under t=920-1000°C) and x values (x=0.25-0.67). The more temperature or pressure, the more content of cubic phase. Optimum initial composition for cubic phase synthesis was found to be x=0.3. From analysis of dependencies (between cubic subcell parameter of $(La_{0.5}Ba_{0.5})CuO_{3-\delta}$ phases and δ value; T_c and FV Cu), which were built on literature and own experimental data we state that for the first time superconducting cubic phase $(La_{0.5}Ba_{0.5})CuO_{2.45(5)}$ (T_c=21K, FV Cu=2.40, Sp.gr. Pm $\bar{3}$m, a=3.9064(8)Å) was synthesised.

P11.10.025 STRUCTURE DETERMINATION OF LEAD INDONIOBATE AND LEAD FERRONIOBATE CRYSTALS. O.Lavrova, R.Kolesova, M.Kupriyanov, Department of Physics and V.Kolesov, Department of Mechanics and Mathematics, Rostov State University, 5 Zorge str., 344090, Rostov-on-Don, Russia.

An x-ray diffraction study of $PbIn_{0.5}Nb_{0.5}O_3$ (PIN) and $PbFe_{0.5}Nb_{0.5}O_3$ (PFN) single crystals was made with MoK_α radiation at room temperature for PIN and at 160°C for PFN. Under an assumption the ideal perovskite structure (the space group O^1_h) are unusually large values of Debye-Waller factors (DWFs) of Pb atoms: B(Pb)=4.80 Å², B(In/Nb)=0.91 Å², B(O)=4.62 Å² and R=0.0923 for PIN; B(Pb)=4.40 Å² , B(Fe/Nb)=0.80 Å², B(O)=1.40 Å² and R=0.0600 for PFN.

An assumption that atoms dynamically or statistically occupy a position 48: (n) of the group O^1_h permits to lower R-factors to 0.0383 for PIN, to 0.0181 for PFN and DWFs: B(Pb)=1.30 Å², B(O)=2.27 Å² for PIN; B(Pb)=1.36 Å², B(O)=0.82 Å² for PFN. A difference synthesis of electron density calculated for the model of ideal perovskite structure shows there are 2 sets of positional parameters with probabilities P_i and (1 - P_i) for PFN.

Disordered displacements of Pb atoms from the 1: (a) position of the group O^1_h in PIN and PFN can be considered as an indication of the formation of metastable polarization regions which are typical for the ferroelectric-relaxors.

P11.10.026 COMPUTATIONAL SIMULATIONS OF NOVEL A-SITE SUBSTITUTED PEROVSKITES. V. Jennings, P.A. Thomas, Department of Physics, University of Warwick, Coventry, CV4 7AL, UK.

The Perovskites (generic formula ABO_3) show many useful properties, such as ferroelectricity, piezoelectricity and high dielectric constant. They are important not only for these properties, but also because their relatively simple basic structure facilitates the study and understanding of the relationship between these properties and the structure.

The structure, minimal energy configurations and possible phases of novel A-site substituted perovskite compounds (as opposed to solid solutions) based on $Na_{(0.5)}Bi_{(0.5)}TiO_{(3)}$ have been investigated for varying dopants on the A-site using computational methods. The methods used were density functinoal theory (FLAPW method implemented using the WIEN97 [1] code) and the Mott-Littleton method (GULP [2] code). Preliminary results of modelling studies on this class of compounds will be presented.

P11.10.027 INVESTIGATION OF THE STRUCTURE AND PHASE TRANSITIONS IN THE FERROELECTRIC CRYSTAL $Na_{0.5}Bi_{0.5}TiO_3$. G.O. Jones, P.A. Thomas, Department of Physics, University of Warwick, Coventry, CV4 7AL, UK.

Sodium-Bismuth Titanate, Na0.5Bi0.5TiO3 (NBT), has the perovskite structure, with general formula ABO3. This is one of a handful of perovskites compounds with substitution at the A-cation site, whereas the majority of the perovoskite compounds substitute on the B-site. NBT was first described by Smolensky and co-workers [1], and to date many of its characteristics have

been investigated[2-4]. However, there is considerable controversy within the published literature about the ferroic nature of the different phases and the temperature range over which they exist.

The results of neutron powder profile refinement at room temperature has revealed a rhombohedral phase (space group R3c), exhibiting an antiphase oxygen octahedra tilt system, giving rise to a doubled unit cell. Cation displacements and octahedral distortions for this temperature are reported. On thermal-cycling an observed pattern change consistent with the loss of the room temperature rhombohedral distortion giving a high temperature cubic phase is seen.

Single-crystal data has been collected using a Bruker SMART system at room temperature and 120K. The results hence far support the neutron diffraction data but suggest either twinning or disorder in the single crystal. The results of refinement of twinning/disordered models are presented and discussed.

P11.10.029 INTERATOMIC BOND STRAINS EFFECT ON FERROELECTRIC PROPERTIES OF $NaNbO_3$-BASED SOLID SOLUTIONS. G.A.Geguzina, N.V. Nastas'ina and L.A.Reznitchenko. Institute of Physics at Rostov State University, 194 Stachki Ave., Rostov-on-Don, 344090. Russia.

Two groups of both synthesised first [1] and famous binary systems of solid solutions (SS) on the basis of perovskite $NaNbO_3$ (NN) with the second components (SC): ANb_2O_6 (1) and $ATiO_3$ (2) (where A=Ni, Cu, Co, Mg, Zn, Mn, Cd, Ca, Sr, Pb, Ba, $(NaBi)_{0.5}$, $(AgBi)_{0.5}$ and $(KBi)_{0.5}$) are considered. Most of these SC are nonisostructured to NN. They have various structure types: columbite, ilmenite, KW-bronze or pyrochlore. Only the Cd,Ca,Sr,Pb,Ba, $(NaBi)_{0.5}$, $(KBi)_{0.5}$ titanates are isostructured to NN. Nevertheless they all form restricted at least SS series on the NN basis. The partial Na atoms substitution with A atom occurs in all of systems, but also Nb atoms are substituted by Ti atoms in (2) systems.

Several regularities of electrophysical properties variation depending on substituting atoms characteristics and interatomic A-O bond strains have been found. The last ones are determined as $\delta_{AO} = (L_{AO}-L^o_{AO})/ L^o_{AO}$ where L_{AO} is strained (real) interatomic A-O bond length in the complex compound or SS and L^o_{AO} is the unstrained (free) one. As the calculations have shown, the high tensile relative strain of Na-O bond and significant compressive relative strain of Nb-O bond are observed in SS. The sharp decrease of A-O bond tension and the sharp increase of Nb-O and Ti-O bonds compression are observed in SS when varying A atoms. The graphic and analytic (by the use of statistical analysis) correlations between Curie temperature, dielectric permittivity, piezoelectric constants, electromechanical coupling factor at one hand and interatomic bond strains, $\delta_{AO,}$ at other hand have been constructed. Given analytic correlations between SS properties and the interatomic bond A-O strains allow to predict SS ferroelectric properties when the computed a'priori interatomic bond strains change in NN-based SS systems.

P11.10.031 STRUCTURAL RELATIONSHIPS OF TRIIODOMETALLATES OF GERMANIUM (II), TIN (II) AND LEAD (II) WITH METHYLAMMONIUM IONS. G. Wittenburg, B. Serr, G. Heckert, H. W. Rotter, G. Thiele*, Institut für Anorganische und Analytische Chemie der Albert-Ludwigs-Universität, Albertstraße 21, 79104 Freiburg i. Br., Germany

Structural investigations show that most of the trihalogenometallates of germanium(II), tin(II) and lead(II) crystallize in distorted structures of the cubic perovskite or in the NH_4CdCl_3-type and undergo temperature and pressure induced phase transitions[1]. In this context the influence of the non-bonding electron pair („lone pair") has been a topic of intensive and actual research.

The triiodometallates AMX_3 with methyl ammonium ions $A=[(CH_3)_{4-x}NH_x]^+$ though form structures related to the hexagonal perovskite (aristotype: $CsNiCl_3$, space group: $P6_3/mmc$). These structures are characterized by linear chains of face-sharing $[MI_{6/2}]$-octahedra. Structural distortions of the simple and highly symmetrical topology of the $CsNiCl_3$-type are induced by the orientation of the counterions and the formation of hydrogen bonds.

Good examples are the compounds $(CH_3)_2NH_2MI_3$, with M=Ge(II), Sn(II), Pb(II), which crystallize orthorhombic (space group: P n a 2_1, Ge: a = 8.911 Å, b = 14.268 Å, c = 7.973 Å; Sn: a = 8.789 Å, b = 14.659 Å, c = 8.294 Å; Pb: a = 8.750 Å, b = 15.155 Å, c = 8.179 Å) and show a characteristic deformation of the I_{12}-anticuboctahedra surrounding the dimethyl ammonium ions and differences in the coordination of the metal cations. The germanium ions are shifted to one of the triangular faces and adopt approximately a [3 + 3]-distorted octahedral coordination. The tin and lead ions show a [2 + 2 + 2]-distorted coordination, where the common octahedral faces are tilted against each other. The different kind of distortion found, may be caused by a stronger lone pair character of the non-bonding electron pair in the germanium compound. This effect is markedly smaller in the tin and lead compounds. In this cases the distortion must be ascribed to the dominance of the spacefilling properties of the dimethyl ammonium counterion and the formation of hydrogen bonds. Close structural relationships between the described dimethyl ammonium compounds and the other triiodometallates with tri- or tetramethyl ammonium ions[2] will be discussed.

Additional information about the dynamical behavior and the deviations from the regular octahedra geometry have been received by vibrational spectroscopy. The results of FTIR- and Raman spectroscopy are in good agreement with the results of single crystal x-ray investigations.

P11.10.032 STRUCTURAL AND DYNAMICAL STUDIES OF THE ORTHORHOMBIC $NaZnF_3$ PEROVSKITE AT LOW TEMPERATURES. A. Ratuszna and J. Rybczynski, Institute of Physics, University of Silesia, Katowice (Poland) Ph. Daniel and J.Y. Gesland Faculté des Sciences, Lab. PEC – UPRES A CNRS n°6087, Université du Maine, Le Mans (France).

$NaZnF_3$, similar to another perovskite as $NaMgF_3$ [1], $NaMnF_3$ [2] possesses an orthorhombic symmetry at and below room temperature. This symmetry is a result of the fluorine octahedra rotation associated to the $a^-b^+a^-$ tilt system [3], as well as the shifting of the Na cations and distortion of these octahedra. Such mechanism leads to stabilise the crystal symmetry without any additional phase change down to the lowest temperatures [4]. Type and value of the tilting angles has been estimated from the splitting of the main diffracted lines on the x-ray powder diffraction pattern. The observed superstructure lines allows to confirm the origin of the tilts around the pseudo-cubic axes. From Rietveld profile refinement the proposed model has been confirmed and additionally from the coordinates of atoms the distortion of ZnF_6 octahedra and displacement of Na cations have been fully determined.

The discussion relative to this distorted perovskite, the bond distances between cations, cation-fluorine, and possible shifting of Na^+ has been enlarged with a Raman study, which has been performed from room temperature down to 40K. In spite of the polydomain character of these samples, Raman spectra of $NaZnF_3$ could be assigned in the orthorhombic Pnma space group thanks to previous group theory analysis and with comparison to the single crystal $NaMnF_3$ [5]. In this framework, 15 Raman lines were then indexed compared to the 24 modes predicted. This work constitutes the first step of a more extensive study devoted to the non well-known antiferrodistortive high temperature phase transition ($T_c \approx 680°C$) occurring in this compound [6].

P11.10.034 CRYSTALLOGRAPHIC STUDY OF THE HIGH- AND LOW-TEMPERATURE FORMS OF $Bi_2(Sr,Ca)_4O_x$. W. Wong-Ng, Q. Huang, R.S. Roth, Materials Science and Engineering Laboratory, NIST, Gaithersburg, MD 20899, USA; J. Kaduk, BP Amoco PLC Research Center, Naperville, IL 60566, USA; and T. Siegrist, Inorganic Chemistry, Lund University, Sweden.

$Bi_2(Sr,Ca)_4O_x$ is an important phase because it is in equilibrium with all three superconductors found in the Bi-Pb-Sr-Ca-Cu-O (BSCCO) system. During processing, $Bi_2(Sr,Ca)_4O_x$ frequently appears as an impurity, therefore crystal chemistry and structural characterization of this phase is deemed important for the study of the BSCCO high-temperature superconductors.

$Bi_2(Sr,Ca)_4O_x$ exists in both high- and low-temperature oxidized forms. The high-temperature form of the composition $Bi_{34.0}Sr_{49.5}Ca_{16.5}O_x$ (prepared at 860°C, yellow) shows a complicated x-ray diffraction pattern as compared to that of the the low-temperature one, which was obtained by annealing the high-temperature sample in oxygen at 620°C (black).

Combined Rietveld refinements of the low-temperature oxidized form $Bi_{34.0}Sr_{49.5}Ca_{16.5}O_x$ using both neutron and x-ray diffraction showed it to be indexable on a distorted ABO_3 perovskite lattice. The structure was found to have a monoclinic space group $P2_1/n$, with lattice parameters a= 8.38917(7)Å, b=5.99436(5) Å, c=5.89592(5) Å and β=89.965(3)°. There are two independent B sites , one of which is mostly populated by Bi^{5+}, and the other about equally by Bi^{5+} and Ca^{2+}. The A site appears to be populated solely by Sr^{2+}. All bismuth atoms adopt distorted octahedral environment. The high-temperature reduced form was found to be also monoclinc with a space group Pc, and a=11.0896 (15) Å, b=5.9734(5) Å, c=19.8216(26) Å, and β=101.504(11)°. Single crystal x-ray study showed the structure consist of two types of Bi atoms. The first type has distorted octahedral coordination while the other one only coordinate to three oxygens. The latter Bi atoms are located around broad channels with lone-pair electrons concentrated in these channels.

P11.10.035 NEUTRON DIFFRACTION STUDIES OF OXYGEN-DEFICIENCY IN HEXAGONAL BARIUM TITANATE. J. M. S. Skakle and D. C. Sinclair, Department of Chemistry, University of Aberdeen, Meston Walk, Aberdeen AB24 3UE, UK, and T. P. Beales, Centre for Superconducting and Electronic Materials, University of Wollongong, NSW 2522, Australia.

Rietveld refinement using neutron diffraction data has been used to determine the crystal structure and oxygen content of a series of reduced, oxygen-deficient barium titanate powders. These were found to crystallise in a 6H-hexagonal perovskite structure, with (O1) oxygen vacancies in the h-BaO_3 layers which separate pairs of face-sharing Ti-O octahedra. No evidence was found for formation of vacancies in the (O2) sites, associated with corner-sharing octahedra. The oxygen deficiency is accompanied by a partial reduction of Ti^{IV} to Ti^{III}, to give general formula $BaTi^{+IV}_{1-x}Ti^{III}_xO_{3-x/2}$; for x=0.3, the material is a band-gap semiconductor at 300K. As the temperature decreases, the material undergoes a change in the conduction mechanism over the range 240-160K, below which the resistivity increases by several orders of magnitude. Low temperature neutron diffraction data showed no evidence for a structural phase transistion: the change in conduction is attributed to variable range hopping of electrons.

P11.10.036 X-RAY DIFFUSE SCATTERING STUDY ON ATOMIC-DISORDERING EFFECTS IN RELAXOR LEAD SCANDIUM NIOBATE. N. Takesue and Y. Fujii, Neutron Scattering Lab., ISSP, U. of Tokyo, Tokai, Naka, Ibaraki 319-1106, Japan, M. Ichihara, Materials Design and Characterization Lab., ISSP, U. of Tokyo, 7-22-1 Roppongi, Minato-ku, Tokyo 106-8666, Japan, H. Chen, Dept. of Materials Science and Engineering, Univ. of Illinois, 1304 W. Green St., Urbana, IL 61801, USA.

Effects of atomic disordering in $Pb(Sc_{1/2}Nb_{1/2})O_3$ (PSN), a type of simple-perovskite relaxor ferroelectrics, were investigated using an x-ray diffuse scattering technique [1,2]. The measurements were performed on two kinds of the single crystals; one has a high degree of ordering of Sc^{3+} and Nb^{5+}, located in the oxigen octahedrons, and the other has the disordered arrangements. Since disordering of the two ions generates size-effect lattice distortions, an unusual behavior of the transition is expected to appear. Results of the ordered crystal indicate lattice instabilities at the Γ and M points in one temperature region, and the freezing behaviors are of a type of normal soft-phonon modes. On the other hand, results of the disordered crystal reveal the diffuse transition behaviors at the two points. An origin of the diffuse feature is suggested to be the lattice relaxation through two-mode partitioning of thermal energy. The distortions are self-accomodated in atomic displacement patterns at the Γ and M points, and are ordered as forms of ferroelectric and antiferroelectric regions. Their frustration may give a sort of dipole-glass states, and is thought to be a cause of dielectric behaviors of PSN.

P11.10.037 REAL STRUCTURE OF FERRO-ELECTRIC LEAD PEROVSKITES. G. Baldinozzi, J.M. Kiat and G. Calvarin, SPMS, CNRS-Ecole Centrale Paris, Grande Voie des Vignes, F-92295 Châtenay-Malabry Cedex, FRANCE

Translational periodicity results in a considerable reduction of the amount of information necessary to model the structure of solids. Any deviation from this ideal description appears as large thermal displacement parameters when this is handled within the Debye-Waller approximation. The two basical hypothesis of this approximation (periodicity and harmonic lattice vibrations) are not well satisfied for ferroelectric compounds [1,2]. In particular, the atoms in ferroelectric solids present random local off-site displacements (multi-well potentials ...) and are generally modeled with very large Debye-Waller factors.

The object of this work is to go beyond the *average* structure approximation usually obtained in conventional Rietveld refinements and to compare different approaches to better model these local structural displacements (real space approach, anharmonic treatments ...).

In order to clarify the structural features of various perovskite compounds ($PbMg_{1/3}Nb_{2/3}O_3$, Pb_2MgWO_6, Pb_2YbNbO_6, ...) presenting compositional and displacive disorder, we have spanned a very large portion of the Ewald sphere up to a **Q** momentum transfer of about 15 $Å^{-1}$ using synchrotron radiation at ESRF. Diffraction patterns at different temperatures (90-900 K) are investigated to study the thermal evolution of disorder in the cubic and low temperature phases.

The knowledge of these deviations from the ideal structure at different temperatures are the necessary basis for the understanding of the relationships between structural modifications and physical properties.

P11.10.038 X-RAY AND MAGNETIZATION STUDY OF Sn DOPED $LaMnO_y$ PEROVSKITE. L. Morales, D. Vega, A. Serquis, G. Alejandro, R. Sánchez, and A. Caneiro, Centro Atómico Bariloche – Instituto Balseiro, Av. E. Bustillo, km 9.500 (8400), Rio Negro, Argentina.

The discovery of "colossal magnetoresistance" (CMR) near the Curie temperature in perovskite-based $La_{1-x}A_xMnO_3$ (A = Ca, Sr, Ba) has generated renewed interest in their magnetic, structural, and electronic properties.

Most of the studied systems correspond to the substitution of La^{3+} by divalent atoms. The effect of substitution of divalent, trivalent and tetravalent cations in the Mn site on the magnetic and transport properties has also been reported in many papers. However, controversial results have been reported on the Sn occupancy site and its effect on the magnetic properties of the LaMnOy perovskite.

In order to investigate the influence of the Sn doping on the physical properties of $LaMnO_3$ manganites, we prepared, characterised and measured the magnetic response of two families of samples with nominal compositions $(La_{1-x}Sn_x)MnO_y$ and $LaSn_xMn_{1-x}O_y$ (x = 0.00, 0.02, 0.05, 0.10, and 0.15). The powder X-ray diffraction data of samples prepared by chemical methods were refined by the Rietveld method and their magnetic susceptibility measured with a SQUID magnetometer. Electron Paramagnetic Resonance (EPR) results are also discussed.

The Mn-O-Mn angle and the Mn-O average distance obtained by Rietveld refinement strongly suggest that Sn replace Mn in the perovskite structure. The defect structure for both families of samples is analysed and its effect on the magnetic response is discussed.

P11.10.039 THE CRYSTAL STRUCTURE OF THE COMPOUND $CS_3MG_2Cl_7$. H.Homeida [1], A.A.Al-Aql, Z.H.Dughaish, A.Al-Jufali, K.M. Al-Sheibani, A. Flimban [2], [1] The Academy of Medical Sciences & Technology, Khartoum, Sudan, [2] King Saud University, Riyadh, Saudi Arabia

The crystal structure of the compound $Cs_3Mg_2Cl_7$ is studied and found to consist of layers of distinct double pervoskite type formed parallel to the plane (001) and the following layers are displaced by $a/\sqrt{2}$ in the direction [110].

The compound is tetragonal of the space group 14/mmm and the lattice parameters are: a =0.505(1)nm, c =2.630(5)nm
The experimental density, D_m = 3.40 g cm^{-3} and the theoretical density D_x=3.45 g cm-3. The number of molecules per unit cell Z=2 and the reliability factor R_w=5.8%.

The Mg^{++},Cs^+(1) and Cs^+ (2),Z=0.1899 (6) for Cs^+ (1) and Z=0.4021 (8) for Mg^{++}. The Mg^{++} is surrounded approximately octahedrally by six chlorine ions, while Cs^+(1) by nine chloride ions, and Cs^+(2) by twelve chlorine ions.

P11.10.040 CONFIGURATION OF A1 AND A2 SITES ON THE MICROWAVE DIELECTRIC $Ba_{6-3x}Sm_{8+2x}Ti_{18}O_{54}$ SOLID SOLUTIONS. H. Sakashita, H. Ohsato, A. Komura and T. Okuda, Nagoya Institute of Technology, Gokiso-cho, Showa-ku, Nagoya 466-8555, Japan

Recently, $Ba_{6-3x}Sm_{8+2x}Ti_{18}O_{54}$ solid solutions have been used for ceramic resonator in microwave telecommunication. The dielectric ceramics have high quality dielectric properties, that is high dielectric constant (ε>80), high quality factor (Q>10000) and low temperature coefficient. The solid solutions have the tungsten bronze type structure with perovskite blocks (A1-site), pentagonal columns (A2-site) and trigonal columns (C-site). In this work, we describe the polyhedral coordination numbers based on the configuration of rhombic A1-sites and pentagonal A2-sites of the solid solutions with x=0.5 as representative composition. The crystal data of $Ba_{4.5}Sm_9Ti_{18}O_{54}$ (x=0.5) with super structure have been obtained by X–ray crystal structural analysis. The crystal data are; Orthorhombic system; Pbnm (No.62); a=12.16(4), b=22.363(8), c=7.662(2) Å, V=2083.7 $Å^3$, Z=2; D_x=5.897g/cm^3; R=4.49%, wR=4.99%. Although the coordination number of the A1-sites of perovskite is usually twelve, in this solid solutions, the sites are distorted to rhombic. We decided that A1-sites became 8 coordination number due to the bond-length and configuration of rhombic sites. Coordination numbers of the A2-sites have been also derived from the bond length and the configuration of pentagonal sites to be 10.

P11.10.041 PHASE TRANSITIONS IN SODIUM NIOBATE. C.N.W. Darlington [1], K.S.Knight [2], [1] School of Physics, University of Birmingham, Birmingham, B15 2TT, [2] ISIS Facility, CLRC Rutherford Appleton Laboratory, Chilton, Didcot, Oxon OX11 OQX

The phases exhibited by Sodium Niobate at room temperature and above have been re-examined using the high-resolution diffractometer, HRPD, at the neutron spallation source, Rutherford Appleton Laboratory. We have found that the symmetry of the phase stable at room temperature, phase P, is monoclinic rather than orthorhombic, and that the multiplicities of the next two phases, R and S, are 2 x 4 x 6, and not 2 x 2 x 6 and 2 x 2 x 2 as reported in the literature. We confirm that the structures of the phases stable above 793K are as reported in the literature, and present details of the evolution of their stuctures with change in temperature. The octahedra at high temperature are tilted and deformed, with the deformation proportional to the square of the tilt angle.

P11.10.042 STRUCTURE CHANGE AND PHASE TRANSITION OF PEROVSKITE-TYPE ABO_3 DUE TO THE IONIC SUBSTITUTION. H.Horiuchi, Department of Natural Science, Faculty of Education, Hirosaki University, Hirosaki 036-8560, Japan, T.Shishido and A.Yoshikawa, Institute for Materials Research, Tohoku University, Sendai 980-8577, Japan, A.Saitow and M.Tanaka, Photon Factory, Tsukuba 305-0810, Japan, and S.Hosoya, Engineering Department, Yamanashi University, Kofu 400-8511, Japan.

Structural change and phase transition of perovskite-type ABO_3 were investigated based upon X-ray powder diffraction data

measured mainly by a laboratory shield tube X-ray source (40kV, 30mA, CuKα) by pyrolitic graphite monochromator and partially by SR for the samples synthesized by a systematic combination of A and/or B with appropriate size of ions[1]. Phases studied in this investigation are RAlO$_3$, RGaO$_3$, BaRO$_3$ etc., where, R is one of a series of rare earth ions of La^{3+}~Lu^{3+} for aluminates and garates, and is Ce^{4+}, Pr^{4+} or Tb^{4+} for BaRO$_3$, in addition, the structures of solid solutions of $(Nd_x,Sm_{1-x})AlO_3$ and $Ba(Pr_{1-x},Tb_x)O_3$ were also investigated in detail on the relationship among their average ionic radius of R, the deformation from ideal cubic lattice and phase transition temperature T_c. Lattice parameters were precisely determined using about 50 reflections which were carefully analyzed by a profile decomposition program[2] for the most of samples. The change from orthorhombic to rhombohedral structure is observed in the phase of $(Nd_x,Sm_{1-x})AlO_3$. The phase transition at room temperature (T_c=22ºC) occurs in the phase with x = 0.73, and the T_c decreases about 35ºC by 1% increase of the amount of substitution of Nd for Sm. All structures of $BaCeO_3$, $BaPrO_3$ and $BaTbO_3$ were confirmed to be orthorhombic with space group of *Pbnm* or *Pbn2$_1$* in this study, although it is reported for $BaTbO_3$ to be rhombohedral in some literature [3]. As a result, no structural changes like (Nd,Sm)AlO$_3$ were observed in the solid solution of Ba(Pr,Tb)O$_3$ at room temperature. Lattice deformation from the ideal cubic is not linearly correlated with the amount of substitution of Pr for Tb in Ba(Pr,Tb)O$_3$. The structures closer to pure compositions with no substitution show a smaller deformation than those with a larger amount of substitution of one ion for another. The structures of $SrCeO_3$ and $BaCeO_3$ were also studied and reconfirmed to be orthorhombic with *Pbnm* or *Pbn2$_1$*. The lattice deformation of $SrCeO_3$ from ideal cubic is much large as compares with that of $BaCeO_3$ which is relatively close to ideal cubic lattice.

P11.10.043 THERMOELECTRIC CLATHRATES. B.C. Chakoumakos, B.C. Sales, D.G. Mandrus [1], J.W. Sharp, G.S. Nolas [2], [1] Solid State Division, Oak Ridge National Laboratory, Oak Ridge, TN 37831 USA, [2] Research and Development Division, Marlow Industries, Dallas, TX 75238 USA

New directions in the research of thermoelectric materials are focusing on clathrate compounds, which exploits the "phonon glass - electron crystal" concept. Atomic displacement parameters (ADP) and thermal conductivity measured as a function of temperature for several promising thermoelectric compounds show that in each case one of the atoms is weakly bound and "rattles" within its atomic cage, resulting in low lattice thermal conductivity. Low lattice thermal conductivity is essential for the design of thermoelectric materials with improved efficiencies. For many clathrate-like compounds, ADP values can be used to estimate the Debye temperature, velocity of sound, heat capacity, mean free path of phonons, lattice thermal conductivity, and Einstein frequency of the "rattler."

Using neutron powder diffraction, the ADP values have been measured for a variety of clathrate and clathrate-like compounds: filled skutterudite-type antimonides ($R_xCo_yFe_ySb_{12}$, where R = La, Ce or Tl), Tl_2SnTe_5, Tl_2GeTe_5, and X_8E_{46}-type germanides ($X_8Ga_{16}Ge_{30}$, X = Sr, Ba). The neutron diffraction data were collected at the High Flux Isotope Reactor at Oak Ridge.

Oak Ridge National Laboratory is supported by the Division of Materials Sciences, U.S. D.O.E. (contract DE-AC05-96OR22464 with Lockheed Martin Energy Research Corporation).

P12.10.001 STUDY OF CRYSTALLOGRAPHIC STRUCTURE OF THE COLOSSAL MAGNETO-RESISTANCE COMPOUND $La_{0.75}Ca_{0.25}MnO_3$. G.Iannone[(1)], C. Meneghini[(2)], S-W. Cheong[(3)], D.D. Sarma[(4)] and P.G. Radaelli[(5)], (1) ILL, avenue des Martyrs BP 156 38042 Grenoble Cedex France, (2) ESRF, avenue des Martyrs BP 220 38043 Grenoble Cedex France, AT&T Bell Lab, (3)Murray Hill, New Jersey 07974, (4) SSCU IISc Bangalore 560 012 India, (5) ISIS Facility Rutherford App. Lab., Chilton, Didcot, Oxon. OX11 OQX United Kingdom.

Manganese oxides with perovskite structure and formula unit $A_{1-x}A'_xMnO_3$ (x<0.30, A= La, Pr,..., A'=Ca, Sr,...) undergo a transition from an insulating to a metallic state near the ferromagnetic order temperature of Mn spins (Tc). A weak magnetic field inhibits this phenomenon so these systems show colossal magnetoresistance (CMR) at Tc. Several experimental works have been performed in order to investigate the crystallographic structure against the atomic species on A/A' site (1) and several theories have pointed out the role of the structural changes that take place at Tc(2). We investigated the crystallographic structure of the compound $La_{0.75}Ca_{0.25}MnO_3$ against temperature (20-800K), applied pressure (0-5Kbar) and magnetic field (0-3Tesla) by means of neutron powder diffraction. All measurements were performed at the Institut Laue Langevin on high-resolution diffractometer D2B.

We observed that the structure is very sensitive to the external condition: in particular a structural phase transition from an orthorhombic Pnma to a trigonal R3c phase takes place in the compound at T = 650K (without magnetic field and at ambient pressure). We observed also that the coupled magnetic and metal insulator transition is induced at constant temperature by the applied pressure or by the applied magnetic field.

P12.10.002 STRUCTURAL STUDY OF EXCIMER LASER TREATED Ag/Co MULTILAYERS EXHIBITING GMR EFFECT. M. Jergel, A. Anopcenko, E. Majková, M. Spasova, and Š. Luby, Institute of Physics of the Slovak Academy of Sciences, Dúbravská cesta 9, 842 28 Bratislava, Slovakia, V. Holý, Laboratory of Thin Films and Nanostructures, Masaryk University, Kotlárská 2, 611 37 Brno, Czech Republic, M. Brunel, Laboratoire de Cristallographie du CNRS, B.P.166, 38042 Grenoble Cedex 09, France, and A.Luches and M.Martino, I.N.F.M. and University of Lecce, Department of Physics, 73100 Lecce, Italy

The work is devoted to a study of interplay between the structure and giant magnetoresistance (GMR) evolution in Ag/Co multilayers exposed to excimer XeCl laser pulses with the fluences of (0.1-0.25) Jcm^{-2} for (1-200) times. Three as-deposited samples, labeled according to layer thickness ratio as Ag_2Co_1, Ag_4Co_1, and Ag_6Co_1, exhibit polycrystalline fcc structure of Ag layers, as revealed by XRD measured both in grazing incidence and Bragg-Brentano modes. The satellites around Ag 111 reflection in the latter mode hint at a superlattice-like character of Ag_4Co_1 multilayer while in other two, the layers are not structurally coherent. Consequently, the grain boundary diffusion of Ag into Co layers occurs due to laser treatment in Ag_6Co_1 leading to the formation of a discontinuous multilayer which enhances the GMR ratio more than twice. In Ag_2Co_1, the temperature window for diffusion is too narrow to improve systematically the GMR ratio as rather thin Ag layers start melting at low fluences. A strong texture in Ag_4Co_1 stabilizes the multilayer structure in the irradiation regime without melting and

the GMR varies non-systematically in a rather narrow interval around the original value. When the Ag melting threshold is reached, rapid solidification produces a granular-like monolayer structure irrespective of the structural character of the original multilayer and the GMR value changes unpredictably in a broad interval. These conclusions are supported by the hard X-ray reflectivity and diffuse scattering measurements at grazing incidence evaluated by the Fresnel algorithm and within the distorted-wave Born approximation, respectively. Transmission electron microscopy and magnetization measurements up to 4.2 K complete the investigation.

P12.10.003 MODELS OF THE CRYSTAL STRUCTURES OF PHASES IN DOPED LANTHANUM MANGANITES. T.V.Novoselova and V.E.Naish, Institute for Metal Physics, Ural Division of Russian Academy of Science, Ekaterinburg, GSP-170, Russia

The crystal structures of all phases typical of phase diagrams for $La_{1x}A_xMnO_3$ manganites have been found by a systematic exhaustion of all possible tilting and Yahn-Tellers modes combinations. The symmetric analysis of any such a combination allows the models of all crystal structures for these manganites to be obtained unambiguously. The particular qualitative differences between two orthorhombic phases so called O' and O" observed by experiment have been brought to light. Their quantitative description has been done and the nature of the distortion modes that form the phase structures has been finally established.

In spite of the fact that a lot of works [1-3] discussed the fascinating structural properties of manganese perovskites does exist yet, we pretend to clarify and systematise the set of phases on the phase diagram in lanthanum manganites.

By an identification of several X-ray diffraction patterns obtained anew the satisfaction agreement of proposed models and experimental data has been achieved. Our conclusions are strongly supported by wellknown results from [1] also.

P12.10.004 X-RAY STUDY ON DIFFUSE SCATTERING IN $(Nd_{0.125}Sm_{0.875})_{0.52}Sr_{0.48}MnO_3$. S. Shimomura, K. Tajima and N. Wakabayashi, Dept. of Phys., Faculty of Sci. and Tech., Keio Univ., 3-14-1 Hiyoshi, Kohoku-ku, Yokohama 223-8522, Japan, H. Kuwahara, Dept. of Phys., Sophia Univ., Tokyo 102-8554, Japan, and Y. Tokura, JRCAT, Tsukuba 305-0046, and Dept. of Applied Phys., Univ. of Tokyo, Tokyo 113-0033, Japan.

A group of compounds, hole-doped manganese oxides with a distorted perovskite structure, $A_{1-x}B_xMnO_3$, has been subjects of great interest because of their colossal magnetoresistance. The compounds with finely controlled ionic radii of the *A* sites, $(Nd_{1-y}Sm_y)_{0.5}Sr_{0.5}MnO_3$ (y=0.875), show a drop in resistivity of more than three orders of magnitude at theferromagnetic transition temperature (T_C), accompanied by discontinuous changes in the lattice parameters. The large resistivity above T_C has been attributed to the presence of polarons.

X-ray scattering study of $(Nd_{0.125}Sm_{0.875})_{0.52}Sr_{0.48}MnO_3$ has revealed that the existence of the diffuse scattering around Bragg peaks in the paramagnetic and insulating phase. The diffuse scattering shows characteristic distribution of its intensity depending on coordinates of reciprocal lattice points. With decreasing temperature from 300K, the intensity of the diffuse scattering increases but seems to vanish abruptly at T_C = 133K. This diffuse scattering can be interpreted as due to a result of the local lattice distortion produced by the localized carriers on the Mn sites (polaron). The number of the polarons presumably increases with decreasing temperature, and below T_C the delocalization of the carriers results in relaxing the local lattice distortion. We have calculated the intensity distributions on the basis of randomly distributed Jahn-Teller polarons. The results of the calculation qualitatively agree with the observations.

P12.10.005 ORDERING PHENOMENA AND ELECTRONIC PROPERTIES OF $Ln_{1-x}Ca_xMnO_3$ PEROVSKITES (Ln =Pr, Sm, Y). Z. Jirak and J. Hejtmanek, Institute of Physics, Prague, Czech Republic, and C. Martin, M. Hervieu, A. Maignan, F. Damay and B. Raveau, Laboratoire CRISMAT, Caen, France.

Behavior of e_g electrons in mixed-valent manganites has been investigated in numerous systems of parent Pnma symmetry with medium and low Mn^{3+} content. With the help of the high-resolution neutron diffraction data, electron microscopy, electrical transport data and magnetic measurements, several low-temperature phases were distinguished and their structure refined. As to the occurrence of charge and/or orbital ordering, magnetic and transport properties, the phase diagram shows three distinct compositional regions. The first region, $0.3<x\leq 0.75$, is characterized by an additional pseudotetragonal compression of the perovskite lattice, which occurs below a critical temperature T_{CO} due to concomitant Mn^{3+}/Mn^{4+} charge and orbital order. This is accompanied with a sudden electronic localization. The magnetic groundstate is of the CE type and, in dependence of the size of interpolated cation, the antiferromagnetic transition takes place at temperatures well below T_{CO}. The samples in the second region, $0.75<x<0.85$, show no charge order. Instead, they undergo a structural transition due to orbital ordering (polarization) of e_g orbitals, which is most readily manifested by a tetragonal elongation of MnO_6 octahedra along the [101] direction with respect to the Pnma lattice. The structure thus acquires a characteristic monoclinic distortion. This transition is followed with a carrier localization, the electrical resistivity is, however, several orders of magnitude lower compared to the charge ordered samples. The antiferromagnetic ordering is of the C type. Finally, the samples with $x\geq 0.85$ preserve pseudocubic metrics down to lowest temperatures. They exhibit the G type antiferromagnetism below T_N~115 K. In addition, ferromagnetic clusters are always present in this regime and are responsible for giant magnetoresistance in x~0.85 samples. The ferromagnetic component achieves maximum for x~0.9 and the compounds (metallic in paramagnetic state) preserve then their high electrical conductivity even below T_N.

P12.10.006 THE $La_{1-X}Sr_XMnO_{3-\delta}$ SYSTEM: A NEUTRON POWDER DIFFRACTION AND INELASTIC LIGHT SCATTERING STUDY. S.- G. Eriksson[1], S. Ivanov[2], J. Eriksen[3], R. McGreevy[3], H. Rundlöf[4], P. Berastegui[5], P. Björnsson[6], M. Rubhausen[6], J. Bäckström[6], M. Käll[6] and L. Börjesson[6], [1]Dept. of Inorganic Chemistry, GU, SE-412 96 Göteborg & NFL, Studsvik, SE-611 82 Nyköping, Sweden, [2]Karpov Institute of Physical Chemistry, RU-103064 K-64 Moscow, Russia, [3]NFL, Studsvik, SE-611 82 Nyköping, Sweden, [4]Inorganic Chemistry, Ångström Laboratory, SE- 751 21 Uppsala, Sweden, [5]Dept. of Inorganic Chemistry, SU, SE-10691 Stockholm, Sweden, [6]Condensed Matter Physics, CTH, SE-412 96, Sweden

The atomic and magnetic structure of $La_{1-X}Sr_XMnO_{3-\delta}$ ($0< x< 0.2$) is controlled by cation composition as well as by oxygen

content. The atomic order and thus the lattice symmetry, is also affected by the temperature.

The samples were prepared from the constituent oxides or carbonates. The total sintering time were more than 2 weeks at temperatures from 1223 K to 1623 K. Neutron powder diffraction data were collected at the R2 reactor, Studsvik, Sweden, and data analysed with the Rietveld program FULLPROF. The light scattering measurements have been performed in backscattering geometry on a Dilor XY800 micro-Raman, and a SPEX Triplemate macro-Raman setup.

We have investigated a series of powdered materials at temperatures between 10 K and 300 K. Most samples, as prepared in air, were single phase, either showing rhombohedral or orthorhombic lattice symmetry. They crystallise in space group R-3c (a= 5.52 Å and c= 13.34 Å: hexagonal setting) and Pnma (a= 5.50 Å, b= 7.78 Å, and c= 5.53 Å), respectively. The change of magnetic structure with temperature and doping was also investigated. The inelastic light scattering data do confirm the change in lattice symmetry, and do also indicate the importance of a coupling of lattice and electronic degrees of freedom for the magnetic phase transition.

In order to obtain a more detailed understanding for the La-Sr-Mn-O system we intend to perform complementary studies on samples prepared under controlled oxygen partial pressure, i.e. on samples with different oxygen content, and also investigate samples under an external magnetic field.

P12.10.007 PHASE SEPARATION AND SPIN/ CHARGE ORDERING IN $La_{1-x}Ca_xMnO_3$ (x=047, 0.5, and 0.53). Q. Huang, J. W. Lynn, R. W. Erwin, D. C. Dender, A. Santoro, NIST Center for Neutron Research, NIST, Gaithersburg, MD 20899, USA; V. N. Smolyaninova, K. Ghosh, and R. L. Greene, University of Maryland, College Park, MD 20742, USA.

$La_{1-X}Ca_XMnO_3$, with x near 0.5 has been the subject of renewed interest due to the competition between ferromagnetic double exchange coupling and charge/orbital ordering. Neutron powder diffraction has been used to study the crystal structure, bonding, magnetic ordering, and the phase relationships and the properties of the system near the metal-insulator transition at x=0.5, as a function of temperature and magnetic field. The high temperature phase (HTP) has the P*nma* symmetry and is ordered ferromagnetically below ~270 K. The low temperature phase (LTP) develops at ~230 K and is ordered antiferromagnetically below 160 K. As the temperature decreases from 230 K to 100 K, the fraction of the LTP increases to 42, 78, and 90% for x=0.47, 0.50, and 0.53, respectively, and remains almost constant on further cooling. The temperature depen-dence of the broadening of the $(031)_{LTP}$ reflection peak indicates that the LTP phase develops in three steps: phase formation with very small crystallite size (from 230 to 200 K); increase of crystallite size (from 200 to 160 K); and increase of the relative proportion in the sample (from 160 to 100 K).

The development of the LTP is inhibited when a magnetic field is applied. For example, for x=0.5, the amount of the LTP is 68% when the sample is cooled in zero field and a magnetic field of 8.5 T is applied at 5 K. On the other hand, only 24% and 58% of this phase is formed when the sample is cooled in magnetic fields of 8.5 and 5 T, respectively. The curves of the magnetic moment, LTP phase fraction, lattice parameters, and Mn-O distances, as a function of temperature, show a change of slope between 230 and 160 K only on cooling, while smooth curves are observed on warming.

P12.10.008 TUNING OF Tc BY CO-DOPING IN LANTHANUM MANGANITE SINGLE CRYSTALS. Suja Elizabeth, Amlan Biswas, S. Brahadeeswaran and H.L. Bhat [1], A.K. Raychaudhuri [2], [1] Department of Physics, Indian Institute of Science, Bangalore-560012, India, [2] National Physical Laboratory, New Delhi-110012, India

Many rare-earth manganites exhibit colossal magnetoresistance in which the magnetoresistance peaks in the vicinity of magnetic and metal-insulator transition. It is relevant to tune the transition temperature (Tc) of these materials closer to room temperature for practical applications. In these perovskites, Tc is known to vary with the average radius <rA> of A-site cation: hence smaller ionic radius, along with divalent lead, in trivalent lanthanum site. Single crystals of co-doped $[La_{(1-y)}Nd_y]_{(1-x)}Pb_xMnO_3$ have been grown by flux technique. Growth temperature and cooling program are optimized and crystals of typical dimensions 3.5x3x2 mm^3 are obtained. Temperature variation of resistivity and susceptibility measurements conducted on these crystals confirm that ferromagnetic transition occurs in the close vicinity of insulator-metal transition. In particular, $La_{0.36}Nd_{0.37}Pb_{0.27}MnO_3$ crystals exhibit transitions at 275K. In addition, a peak magnetoresistance of 65% is realized in these crystals near this temperature at a relatively low magnetic field of 3 Tesla. Tuning of Tc without compromising important properties like MR is a significant achievement of this study.

P06.11.001 STRUCTURE OF SINGLE CRYSTALS Fe-Ni ALLOYS AFTER NITRIDING. V.E. Danil'chenko, Institute for Metal Physics, Academy of Sciences of Ukraine, 36 Vernadsky Blvd., 252680 Kiev, Ukraine

X-ray method of single crystals are used to investigate structure state of Fe-Ni alloys after nitriding. The nitriding was performed in the mixture of ammonia and 10-25 % hydrogen at 400-850 °C of $0.5 \cdot 10^{-4}$ min. The sample, quenched in cold water immediately after nitriding, were austenitic at room temperature.

It is found first stages of forming nitrous austenite. Parameter of nitrous austenite lattice deduced during nitriding to five minute and remained practically unchanged later on. The γ′-nitride Fe_4N with fcc lattice is formed in diffusion layer of alloy with 30 wt. %N. He appear after achievement limit equilibrium concentration of nitrogen in γ-solid solution. Diffusive strips, uniting the reflection of γ′-nitride and nitrous austenite with initial austenite, explained by coherence of lattice of these phases.

During nitriding by electric heating are formed fcc γ-nitride and hcp ε-nitride. The γ′- and ε-nitrides are formed as polycrystalline component in the initial single crystalline matrix. In alloy with 30 wt. %N and 5 wt. %Ti γ′-nitride is of single crystalline nature.

The solubility limit of nitrogen is increasing in alloy, contenting 5 wt. %Ti. The γ′-nitride in diffusional layer of alloy with 30 wt. %Ni had ordered structure and correspond composition Fe_3NiN, in alloy with 30 wt. %Ni and 5 wt. %Ti - $Fe_3(Ni, Ti)N$.

P06.11.002 EFFECT OF THE LASER TREATMENT ON RECRYSTALIZATION OF SINGLE CRYSTAL α-IRON. V. I. Bondar, V.E. Danil'chenko, B. Polchuk, Institute for Metal Physics, Academy of Sciences of Ukraine, 36 Vernadsky Blvd., 252680 Kiev, Ukraine.

Laser pulse heating of α-iron single crystals with a beam energy density from 5 to 20 J/mm^2 visually did not change the above-mentioned parameter. A further increase in the energy of the laser beam led to no changes in the diffraction pattern. However, heating in the regime of visually observed surface melting resulted in significant changes in the diffraction pattern and, consequently, in the structural state of the initial a-iron single crystal. The rapid cooling of the liquid surface layer led to the formation of polycrystalline α-iron with the bcc lattice whose parameter coincided with the lattice parameter of the initial specimen. This is evidenced by the formation of continuous Debye reflections of α-iron passing through all the reflections of an initial single crystal.

When the energy density reached 22 J/mm^2 qualitative changes in diffraction patterns were observed. In this case, in addition to the α-phase, the γ-phase was identified as isolated reflections from single-crystal grains. No polycrystalline component of the γ-phase was observed. In different experiments, the number of orientations of the γ-phase lattice with respect to the initial single-crystal a-phase varied from two to four.

When the energy densities were high (higher than 26 J/mm^2). laser remelting did not lead to γ-phase formation. Consequently, γ-phase formation upon laser treatment was observed only in a specific range of energy densities (18-22 J/mm^2).

P06.11.003 THREE-WAVE GRAZING INCIDENT X-RAY DIFFRACTION: DIRECT PHASE DETERMINATION OF SURFACE REFLECTION. Y.S. Huang, S.L. Chang, and C.H. Chao, Department of Physics, National Tsing Hua University, Hsinchu, Taiwan, R.O.C. M.T. Tang, Synchrotron Radiation Research Center, Hsinchu, Taiwan, R.O.C., and Y.u.P. Stetsko, Department of Physics, National Tsing Hua University, Hsinchu, Taiwan, R.O.C. and Chernovtsy State University, Chernovtsy, Ukraine.

Three-wave grazing incidence x-ray diffraction is realized by tuning the x-ray photon energy to match the incident wavevector with the coplanar momentum transfers of crystal surface in-plane reflections. Near the resonance energy, the observed specularly diffracted intensities decreasing at lower energies and increasing at higher energies or vice versa reveal the effects of reflection phases due to the coherent interaction of x-ray surface waves. This experiment thus provides a new way of direct phase determination for surface in-plane reflections. This phasing technique has been applied to overlayered systems and the corresponding interface structures will be reported and discussed.

P06.11.004 A RECIPROCAL LATTICE SIMULATION TO EPITAXIAL THIN FILMS IN THE FOUR-CIRCLE DIFFRACTOMETER GEOMETRY. Ryouichi Yokoyama and Jimpei Harada, X-Ray Research Laboratory, Rigaku, Tokyo, Japan

A new method has been developed which simulates reciprocal lattices in thin crystalline films. In characterizing of epitaxial thin films on some substrate crystal, it is essential to know the crystallographic relationships between those thin crystals. Since such an X-ray measurement is usually based on the four-circle diffractometer geometry, a technique to determine the crystal orientation matrix which has been utilized in the single crystal structure analysis was applied to the thin film study. The complicated mutual relationships between several thin films and a substrate crystal were found to be determined within the accuracy of less than 0.01 degrees in omega angle by the crystal orientation matrix determined. The present simulation is also designed so as to visualize the mutually related reciprocal lattices of thin crystals, the limiting sphere and the Ewald sphere with an intuitive way. Thus it is very easy to find out scattering condition of any symmetrical and asymmetrical settings, with grazing incidence. Furthermore, as the movement of the reciprocal lattices in CRT was connected with the motor drivers for four circle goniometer, any measurements of X-ray scattering from thin films were fully automated by this guide.

P06.11.005 GROWTH OF GE AND PB ON GE(113) SURFACES STUDIED BY X-RAY DIFFRACTION AND LEED. M. Albrecht, A. Hirnet, A. Iglesias, M. Gierer, W. Moritz D. Wolf and H. Schulz, Institute of Crystallography and Applied Mineralogy, University of Munich, 80333 Munich, Fed. Rep. of Germany

The (113) surfaces of Ge and Si are very stable and exhibit a surface energy nearly as low as that found for the (100) surfaces [1] but do not exhibit two rotational domains. The (113) surfaces are therefore possible candidates for growth of Si-Ge multilayers. The clean surfaces are stabilised by subsurface interstitial atoms which form a (3x1) superstructure at room temperature [2,3]. At low temperatures the interstitial sites order and a (3x2) structure is formed. We have studied the homoepitaxy of Ge on Ge(113) and the influence of Pb on the growth process. The measurements have been performed using synchrotron radiation at HASYLAB with a new UHV x-ray diffractometer which allows to study the

growth process in situ. The results show that at a temperature of 450 K and at submololayer coverages Ge on Ge(113) forms islands. The surface becomes rough with increasing coverage. At 800 K the surface remains well ordered and Ge grows in a step flow modus. The roughness and the island size as a function of substrate temperature has been investigated with SPA-LEED measurements.

Pb grows on Ge(113) in the Stranski-Krastanov mode. Two ordered phases exist with one and two Pb atoms per (1x1) unit cell. At submonolayer coverages Pb removes the (3x1) reconstruction and terminates the Ge(113) surface by substitutional sites. At a coverage above 1 monolayer Pb forms islands. Pb does not intermix with Ge and is a possible surfactant for the growth of Ge on Ge or Si. Our results show little influence on the homoepitaxy of Ge on Ge(113) probably because the low desorption temperature of about 600 K.

P06.11.006 HIGH RESOLUTION X-RAY MULTI-BEAM DIFFRACTION STUDIES OF THIN FILM AND INTERFACES. M.V.Kovalchuk, L.Samoilova, A.Kreines, I.Orlov Institute of Crystallography RAS, Leninsky pr. 59, 117333 Moscow, Russia

X-ray multiple diffraction (XMD) is known as an effective tool to solve the phase problem in X-ray crystallography. If one of diffracted beam is weak (i.e. on the "tail" of rocking curve) it can be considered by analogy to optical holography as a reference one and its intensity is determined by phase ratio between amplitudes of incident beam and other (strong) diffracted one. Similar effects in Renninger scheme can be used to study thin surface layer structure of nearly perfect crystals, heterostructures [1] and interface characterization of thin films [2] and buried ?-layers. In this work we have studied theoretically and experimentally the three-beam diffraction from InGaP(0.8mkm)/GaAs(111), InGaP(0.5mkm)/GaAs(111) and Ga As(5.5nm)/GaInAs(2nm)/ GaAs(111) heterostructures. The modulation of the intensity of the secondary, weak reflection in the vicinity of the Bragg condition of the primary, strong reflection allows to determine the film thickness, lattice mismatch, tetragonal distortions and, for thin film, the bond length at the interface.

P06.11.007 THE FORMATION OF MARTENSITE AND ITS ORIENTATIONS IN SURFACE LAYER OF LASER IRRADIATED Fe-Al-C ALLOYS SAMPLES. E.N.Dzevin, V.A.Andryushchenko. G.V.Kurdyumov Institute for Metal Physics NAS Ukraine, 252142 Kiev-142, Vernadsky blvd. 36, Ukraine.

The structure of martensite which forms in nearsurface layer of pulse laser irradiated quenched Fe-Al-C alloys samples have been investigated by X-ray technique. After cooling down of the austenite Fe-4%Al-2%C single crystals to the liquid nitrogen temperature, undergone to multiple pulse laser irradiation along the [001] axis of the f.c.c. austenite crystalline lattice with surface melting off, the martensit transformation occurs. The martensite which was formed has a various tetragonality degree and various orientation concerning to austenite on different depth from melted surface. On the stereografic projections the martensite poles (001) and (10.0) asymmetrically situated around austenite (100) and (110) poles, as against this fixes after usually quenching (Greninger-Trojano oriental rates, 48 variants). The quantity of the martensite poles decreases on some depths and the halfwidth of martensite $(002)_\alpha$ difraction spots less nearly two times than another one of high degree tetragonality martensite. This fact has been explained by disturbance of coherency between phase components in these layers.

In single crystals of Fe-8%Al-2,5%C alloy laser irradiated along $[111]_\gamma$ direction, the picture after cooling down to the liquid nitrogen was complicated by presence an α-martensite which was oriented concerning to austenite by Nishijama oriental rates in initial (after quenching) state. The analysis of α-martensite elementary crystal lattice sell changes and its variants of orientations let us to do an assumption that surface layer consist of some streaks. The structure of these streaks have been defined.

P06.11.008 RECONSTRUCTION OF TRANSITION METAL OXIDE SURFACES, T. Gloege, H. Zajonz, F. Wendler, H.L. Meyerheim, W. Moritz and H. Schulz, Institut of Crystallography and Applied Mineralogy, University of Munich, Fed. Rep. of Germany

The structure of oxide surfaces has been far less frequently studied than metal and semiconductor surfaces in spite of their technical importance in various fields such as heterogeneous catalysis and thin film technology. The reconstruction of these surfaces and the role of defects in their chemical and physical properties are not well understood. This is due to the complexity of the first principles structure calculation of these structures and because of sparse experimental data. In many cases the transition metals occur in different oxidation states so that the surface composition cannot be predicted by the simple requirement of an electrostatically neutral surface. We have studied the reconstruction of the clean surfaces $TiO_2(100)$, $Fe_3O_4(100)$ and $Cr_2O_3(0001)$ and one adsorbate structure of K on TiO2(100) by surface x-ray diffraction. The preparation of the clean single crystal surfaces in UHV followed standard methods. In all three clean surfaces we found that defects play an important role. The (100) surface of rutile, TiO2, exhibits a (1x3) reconstruction which can be described by microfacetting due to the formation of (110) planes and a partially populated interstitial site. The surface is terminated by a Ti^{3+}[2]. The Fe_3O_4 surface exhibits a c(2x2) reconstruction which is characterised by a half occupied Fe layer and additional occupation of interstitial sites in subsurface layers. The $Cr_2O_3(0001)$ exhibits no ordered superstructure at room temperature. The surface is terminated by a disordered Cr^{3+}-layer in which 2/3 of the sites are occupied and 1/3 of interstital sites below the top oxygen layer is occupied by Cr leaving an electrostatically neutral termination. The only adsorption system studied so far is K on $TiO_2(100)$ which forms a c(2x2) structure. This surface is characterised by a half occupied Ti-layer oxygen defects and strong relaxation over several subsurface layers.

P06.11.009 NEUTRON STANDING WAVES UNDER THE TWO BEAM DYNAMICAL DIFFRACTION. V. Nosik, M. Kovalchuk, S. Zheludeva; A.V. Shubnikov, Institute of Crystallography, Russian Academy of Sciences

The well known X-ray Standing Wave (XSW) method is based on the registration of angular variation of the yield of secondary process excited by dynamical X-ray wave field, (see e.g. [1]). The first experimental evidences of variation of secondary process (gamma quanta emitted due to neutron capture) under the neutron dynamical diffraction were obtained during the search of neutron's Borrmann effect [2] and as far as we know for more then 30 years these effects were out of the scope. It is

surprising but neutron standing waves were discovered in 1956, i.e. BEFORE the X-ray ones.

The principle of this experiment is well known. Coherent superposition of diffracted and transmitted waves inside the crystal forms the neutron standing wave with antinodes changing its position relatively the atoms in diffracting plane with the variation of the incident angle of primary radiation. The period of NSW (as well as XSW) is equal to interplanar distance for given reflection (1-10Å) and can be varied by choosing the proper reflex. In neutron diffraction experiment the modulation of absorption due to NSW is revealed through the "lack" of intensity from the side of low angles of rocking curve, in secondary process yield the formation of NSW can be seen through the variation of angular dependence [2] .

The developed theory explains the angular modulation of secondary process yield (products of nuclear reaction: gamma quanta emitted due to the neutron capture, alpha-, beta- particles and conversion electrons) due to the formation of neutron standing waves (NSW) under the condition of Bragg and Laue diffraction of thermal neutrons in crystal. Due to the small absorption the neutron diffraction provides us with a perfect nuclear yardstick with the period about 1-10Å and the tick distance about nuclear size (10^{-15} m). The variety of the secondary process and magnetic scattering of neutrons opens new possibility for structure characterization. This theory was successfully applied for the explanation of the data obtained in [2].

P06.11.010 DYNAMIC THEORY OF X-RAY DIFFUSE SCATTERING IN MULTILAYERS WITH VERY ROUGH INTERFACES. A.V.Andreev, I.R.Prudnikov, Physics Department, Moscow State University, Moscow 119899, Russia

Grazing incidence X-ray diffuse scattering is now widely used for investigations of interface roughness in multilayered structures and obtaining information on roughness parameters. Up to now, the theoretical approach based on Distorted Wave Born Approximation have been commonly used for the theoretical description of diffuse scattering. It is well known that the area of this method application is restricted to the roughness of the small root-mean square (rms) height [1]. In our paper we have used the dynamic scattering theory which is valid in the case of arbitrary rms height of roughness [2]. The roughness profiles at different interfaces were modeled by harmonic functions, i.e., sine or cosine, with different amplitudes and phases. This model enables us to simulate the different correlation properties of the interface roughness. The variation of the sine amplitudes with the depth makes it possible to study the influence of the of the vertical correlation onto the angular spectra of scattering. The variation in the phases of the successive layers enables to model the different degree of roughness replication from substrate to upper layer. The variation in the lateral correlation length can be modeled by beating of amplitude of the two sine functions with the close but different periods. In the case of the harmonic relief of interfaces the Bragg sheet is really a sequence of the maxima. The variation in the correlation properties of interfaces results in the variation of the Bragg sheet envelope as well as in the position and angular width of the successive maxima. The results of the computer simulations show that the relation between the intensities of the adjacent peaks depends significantly on the vertical correlation length. The equidistant phase shift for the successive layers results in the tilt of the Bragg sheets.

P06.11.011 RAPID ANALYSIS OF THE SURFACE ROUGHNESS OF GLASS SUBSTRATES. I.Pape, B.K.Tanner, Department of Physics, University of Durham, South Road, Durham, DH1 3LE, UK. M. Wormington, Bede Scientific Inc., 14 Inverness Drive East, Suite - G104, Englewood, Colorado 80112, USA.

The control of surface roughness is extremely important in the production of float glass, as high roughness values increase the amount of diffusely scattered light. Grazing incidence x-ray scattering is an extremely sensitive technique for the study of surface roughness. Through simulations of the diffusely scattered x-rays, roughness values in the range 1 - 30Å can easily be obtained. An unfortunate drawback of this method is the time taken in producing accurate simulations limits the throughput of samples which can be achieved in a quality control environment.

Savage *et al*. [1] proposed a method for deducing the surface roughness, σ, from the diffuse scatter without the need for simulations. This method works well, but underestimates the true roughness values as some of the diffuse scatter is cut-off by the shadow of the specimen edges. We have extended this technique by correcting the roughness values using a look-up table based on the Distorted Wave Born Approximation. To test this approach, grazing incidence x-ray scattering measurements were performed on a series of glass specimens produced by Corning Glass. Simulations of the specular and diffuse scatter were performed for several x-ray optical conditions, leading to a high degree of confidence in the surface roughness values obtained. For all samples, agreement within experimental error was found between the roughness obtained from full DWBA simulations and that deduced from the above method. We suggest that this method is advantageous in a production line environment, where large numbers of similar samples are encountered.

P06.11.012 CHARACTERIZATION BY X-RAY DIFFRACTION OF YBACUO THIN FILMS ON Si SUBSTRATE WITH BUFFER LAYER. S D. Boschetto [1], F. Schimdt [2], [1] Institute of Optic and Quantum Electronics, F. Schiller University of Jena, Jena, Germany, [2] Institute of Solid State Physics, F. Schiller University of Jena, Jena, Germany.

It is already known that the YBaCuO thin film deposited on SiTiO3 as substrate gives really good superconduction properties. The combination of high temperature YBaCuO superconductor and semiconductor technology makes interesting the use of silicon as a substrate because it is economical and it is between the most useful element to made the electronic circuits. The incorporation of buffer thin films is essential for the refinement of YBaCuO thin films deposited on such a substrate. One possibility is to use CeO_2 and $Y:ZrO_2$ as a buffer. The YBaCuO thin films as well as the buffer interfaces are made by laser ablation and sputter deposition at different substrate temperatures. X-ray diffraction methods permit to point out the crystalline perfection of the grown YBaCuO thin films concerning the crystallite orientation, crystallite size and inherent lattice tension and makes possible the correlation to the superconductor properties. So it is possible to compare the results of the well-known YBaCuO thin films on $SiTiO_3$ as substrate with YBaCuO thin films on silicon as substrate.

P06.11.013 THE STRUCTURE OF Cu-V MULTILAYER FILMS. V.P.Ampilogov, V.M.Ievlev, E.K.Belonogov, Department of Physics, Voronezh State Technical University, Moskovskii Prospekt 14, 394026 Voronezh, Russia.

The multilayer Cu-V films were received by electron-beam evaporation. The structure and orientation of Cu and V

layers were investigation by the methods of X-ray diffraction and transmission electron microscopy in depending on the number of bilayers. There was a good agreement between the experimental and calculated X-ray spectra in the absence of transition regions between the metal layers. The multipositional epitaxial nucleation of V on Cu takes place with the orientational relationships allowed by (011)[21$\bar{1}$] V ‖ (100)[011] Cu (*), which leads to the formation of oriented polycrystal structures of high dispersity. The effect of bilayers is in the increase of metal film dispersity, the increase in deviation from the exact azimuthal orientations (*), and, in the long run, in the formation of axial texture.

P06.11.014 X-RAY DIFFRACTION ANALYSIS OF THIN ALUMINA FILMS. O.A. Yakovleva, Mathematics Department, Petrozavodsk State University, Petrozavodsk 185640, Russia, A.N. Yakovlev, Physics Department, Petrozavodsk State University, Petrozavodsk 185640, Russia and N.M. Yakovleva, Physics and Mathematics Department, Karelian State Pedagogical University, Petrozavodsk 185680, Russia.

Widespread use of thin oxide films of aluminium makes it necessary to investigate their electrical and structural behaviour. Many workers have carried out intensive studies of the electrical properties of alumina as dielectric. However, in the case of amorphous oxides only little attention has been paid to the problem of short-range order (SRO) as well as if and how exposure to temperatures close to the transition into crystalline state can alter SRO and hence can lead to the changes of electrical properties of oxides. The information on previous investigations concerning the SRO of amorphous oxides is limited. But only the application of pair functions method (PFM) made possible the construction of distribution of electron density of amorphous materials resulted from the experimental x-ray scattering intensities to obtain the complete structural data i.e. the radii of the co-ordination spheres and their blurring, the co-ordination numbers.

In the present work x-ray diffraction analysis and direct observations by scanning electron microscopy of amorphous oxide films of aluminium have been made. Aluminas were prepared by the method of anodisation of aluminium foil in different electrolytes. The SRO-parameters for four co-ordination spheres have been calculated by the PFM, and SRO identification has been made. Special attention is given to explanation of the possible mechanism of SRO formation under such conditions. Series of experiments (also including high temperature x-ray diffraction) have been initiated to study the effect of the thermal treatment on amorphous oxides in pre-crystallisation temperature region. The SRO structural changes are first analysed. Crystalline phase growth dynamics due to thermal treatment will be also discussed beginning with the budding of crystalline phase and ending with complete crystallisation.

P06.11.015 SURFACE ROUGHNESS IN LANGMUIR-BLODGETT MULTILAYER FILMS STUDIED BY AFM AND X-RAY DIFFRACTION. T. Pusztai [1], N. Rozlosnik, G. Antal [2], [1] Research Institute for Solid State Physics and Optics, H-1525 Budapest, P O Box 49, Hungary, [2] Eötvös University, Department of Atomic Physics, H-1518 Budapest, P O Box 32, Hungary.

Langmuir-Blodgett multilayer films consisting of up to 100 layers of cadmium substituted arachidic acid on silicon wafer have been studied. The samples were deposited from water subphase containing Cd2+ ions using an alternate layer LB trough under computer control. Long range orientational order was observed by AFM on the surface of films with a small number of layers. The X-ray reflectivity curves shows regularly spaced Bragg peaks arising from multilayer structure. The periodicity of the LB film is in agreement with twice the estimated molecular length, which confirms that the multilayer structure has a bilayer (Y) configuration. We demonstrate that the growth process of the LB films must have been stochastic. Our results are in good agreement with the Eden model of growing.

P06.11.016 INFLUENCES OF DOPED-MATERIALS ON THE CREATION OF CLUSTERS IN THE SN(Y)OX-THIN FILMS. Vo Vong [1], Nguyen Thi Huong [2], [1] Laboratory of Electron Microscopy , National Centre for Natural Science and Technology , Nghiado Caugiay - Hanoi, Vietnam, [2] Department of Physics , National University of Hanoi, Nguyen Trai str. Dong Da District - Hanoi, Vietnam.

In the paper we report the new results, which we received recently by study the Sn(Y)Ox - thin films. Y in the formular is a doped material. The films made by evaporating method. Tin (Sn) and antimony (Sb) or noble metals such as silver (Ag), platinum (Pt), which are doped material, were evaporated from a molybdenum boat in high vacuum of 2.10^{-6}Torr.

Tin and the doped material - one of the Sb , Ag or Pt - which have mass - rate from of 6 : 1 to 10 : 1 pure 99,999%, were put on two differential boats. And then both boats were simultaneously heated to evaporate materials on it.

The films of two mixed metals (Sn and Sb , Ag or Pt) were deposited on substract (110)-NaCl monocrystal. In following, the films were annealed in atmosphere, which is rich oxygen at the temperatures: 300, 400 and 500 ^{o}C in 120 minutes.

The creation of clusters in each temperatural step was studied by X-ray diffraction (D-5000) and transmission electron microscope EM-125K. Through the electron microscopy imagers and X-ray diffraction patterns, the influences of doped materials on the creation of clusters were discussed.

The optical and electrical properties of the Sn(Y)Ox thin films were investigated in the work too.

Vo Vong , Nguyen An , Nguyen Thi Huong , Proceedings of the 2nd International Workshop on Materials Science (IWOM'95). Part 1 p. 232 – 235.

P06.11.017 SOFT X-RAY MAGNETIC DICHROISM IN $R_{1-x}M_x$ AMORPHOUS FILMS (R= RARE-EARTH, M= Co, Fe). O. Zaharko, H. Grimmer, PSI, Villigen, Switzerland, H.-Ch. Mertins, F. Schäfers, BESSY, Berlin, Germany.

Rare-earth (R)/transition metal (M) amorphous films are widely used as high-density recording media [1] due to a number of useful properties concerning magnetization, Curie temperature, compensation temperature, uniaxial anisotropy, coercivity and Kerr rotation.

R/M amorphous films show considerable X-ray magnetic circular (MCD) and linear (MLD) dichroism [2] at the $M_{4,5}$-edges of R- and the $L_{2,3}$-edges of M-elements. These effects are governed by the interplay of various effects: exchange and spin-orbit coupling, presence of a crystal field.

We propose to make use of these properties and to employ R/M amorphous films in a new tunable polarimeter for the characterization of a synchrotron beam's polarization state in the 700 - 1400 eV range.

Characterization of the sputtered R/M films and the first results on the MCD effects in Ho/M films measured by the transmission method at beamline PM4 at BESSY using the soft X-ray polarimeter [3] are presented.

P06.11.018 NEW TYPE OF INTERFERENCE FRINGES IN BRAGG-CASE SECTION TOPOGRAPHY OF IMPLANTATED $A^{III}B^{V}$ CRYSTALS. K. Wieteska[1], W. K. Wierzchowski[2], A. Turos[2], W. Graeff[3], G. Gawlik[2] and R. Grötzschel[4]: [1]Institute of Atomic Energy, Świerk-Otwock, Poland, [2]Institute of Electronic Materials Technology, Warsaw, Poland, [3]HASYLAB at DESY, Hamburg, Germany, [4]Rossendorf Research Centre, Germany. 11.11 16.03

A new type of interference fringes was obtained in synchrotron patterns exposed using synchrotron white beam limited by 5 μm slit in the implanted GaAs and $Al_xGa_{1-x}As$ layers. The implantations were performed with 170 keV protons, 1.5 MeV Se and 1.0 MeV Si ions with the depth range of induced effect not exceeding 1.5 μm, as it was evaluated with a number of characterisation methods. Some implantations performed at channeling condition were also studied. A relatively large film-to crystal and small glancing angle of 4° were used to enhance the deformation effect revealed by the white beam topograph.

The new intense interference fringes were observed only in the cases when the strain profiles was expected to produce a maximum situated under the distinct shot-through layer. That was mostly in the case of the proton implantation and in the case of selenium implantation at channeling condition. On this reason they provide a new possibility of the present method of very effective identification of the presence of the shot-through layer. The fringes appeared in the area between more distinct stripes corresponding to the maximum from the shot through layer and the maximum of the mostly deformed layer. It was also found that the fringes are revealed along the directions corresponding to the change of diffraction vector corresponding to the tetragonal deformation differently from the fringes observed in the case of Bragg-case section and pin-hole patterns in bent crystals.

The possible mechanism of the fringes is the interference of the radiation diffracted at the same angle by the two lamella on both sides of the mostly deformed layer with the same tetragonal deformation. This model provides an easy way of the approximate simulation of the fringes based on the kinematical theory of diffraction.

P06.11.019 THE DETERMINATION OF THE IMPLANTATION INDUCED STRAIN PROFILES IN GaAs AND $Al_xGa_{1-x}As$. W.K. Wierzchowski[1], K. Wieteska[2], A. Turos[1], W. Graeff[3], G. Gawlik[1] and R. Grötzschel[4]: [1]Institute of Electronic Materials Technology, Warsaw, POLAND, [2]Institute of Atomic Energy, Świerk-Otwock, POLAND, [3]HASYLAB at DESY, Hamburg, GERMANY, [4]Rossendorf Research Centre, GERMANY. 11.11 16.03

The MOCVD grown $Al_xGa_{1-x}As$ with $x=0.45$ and GaAs with initial dislocation density smaller than $10^3/cm^2$ were implanted with different doses of 1.5 MeV Se and 1.0 MeV Si ions and 170 keV protons at room and liquid nitrogen temperatures. The energies of ion were chosen to produce the similar expected range of ions, close to 0.7 μm while the range of doses were chosen to exceed distinctly the expected amorphisation level. Part of the samples were thermally annealed at 300°.

The samples were studied with a number of complementary X-ray methods realised both with synchrotron and conventional sources of X-rays. The most important method of characterisation was recording of rocking curves using highly monochromatized synchrotron beam of very small size and the white beam Bragg-case synchrotron topography. The synchrotron rocking curves and plane-wave topographs reproduced many details of interference maxima and were used for strain profile analysis based on fiting of the simulated rocking curves obtained by numerical integration of the Takagi -Taupin equations.

It was found that the amorphisation of $Al_xGa_{1-x}As$ took place only when the implantation was performed at liquid nitrogen temperature. Differently the increasing of the dose at room temperature causing the saturation of the implantation induced lattice parameter change. Together with that we observed the flattening of the strain profile close to the surface and the increase of the thicness of the layer with introduced lattice parameter change. The last was 1.5-2×greater than the expected ion range and we found a number of evidence that it is not caused by the channelling.

The distinct shot through layer with lattice parameter smaller than deeper mostly deformed layer was stated only in the case of the lowest Se and Si ion doses, but it was mostly visible in case of proton implantation and Se and Si implantation at channeling condition. The shot-through layer often caused some additional interference features in the rocking curves but the distinct evidences were obtained from the Bragg-case section topographs.

It was also proved that thermal annealing at 300° decreased the value of the implantation induced strain at its whole depth range, proportional to the annealing time.

P06.11.020 ATOMIC STRUCTURE OF THE THERMAL OXIDE LAYERS ON Si(001), (111) AND (110) WAFERS. T.Shimura, and M.Umeno, Department of Material & Life Science, Osaka University, 2-1 Yamadaoka, Suita, Osaka 565-0871, JAPAN.

In the X-ray diffraction patterns from the thermal oxide layers on Si(001), vicinal (111), and (110) substrates, the extra diffraction peaks with the Laue-function-like intensity profile were observed, of which period corresponds to the inverse of the film thickness. This result means that the oxide layers do not have simple amorphous structure, but have ordered structure not only close to the interface, but also in the whole part of the oxide layer. Furthermore, the ordered structures are distinct from each other, because the extra peaks from the oxide layers with the different substrate were observed at their respective positions in reciprocal space.

The pseudo-cristobalite structure has been proposed for the oxide layers on Si(001) substrates, which can explain the diffraction pattern very well [1]. Therefore, the pseudo-cristobalite structure was extended for the oxide layers on Si(111) and (110) substrates, in which the oxygen atoms were located between the Si atoms and the lattice spacings perpendicular to the interface were approximately twice as that of the each substrate, while the lateral lattice spacings were exactly the same as that of the substrate. These structures have some problems from the crystallographic view point, because they might contain different bond lengths and angles. However, it was found that the extra peaks from the oxide layers were reproduced in the simulated diffraction patterns by Fourier transform of the models at the same positions as were observed in the X-ray diffraction experiments.

I.Takahashi, T.Shimura, and J.Harada (1993), J. Phys.: Condens. Matter 5, 6525.

P06.11.021 X-RAY SCATTERING FROM THE CRYSTALLINE SiO_2 IN BURIED OXIDE LAYERS OF SIMOX WAFERS. Takuji Hosoi, Takayoshi Shimura and Masataka Umeno, Department of Material & Life Science, Graduate School of Osaka University, 2-1 Yamadaoka, Suita, 565-0871, JAPAN.

We have investigated the existence of crystalline SiO_2 in buried oxide (BOX) layers of SIMOX wafers by the x-ray diffraction technique. The extra diffraction streaks perpendicular to the interfaces were found at the middle of reciprocal lattice points of Si, such as 0.5 0.5 L and 1.5 0.5 L. This means that there exists an ordered structure in SIMOX wafers, having epitaxial relationship with the Si substrates. In order to investigate the position and distribution of the ordered structure, several samples

with different thicknesses of the BOX layers were prepared by HF etching. The peak intensity of the extra diffraction streak at the position of 0.5 0.5 L in reciprocal space decreased with the reduction of the BOX thicknesses. The streak disappeared when the BOX layer was completely removed. This indicates that the streak originates from the crystalline SiO_2 in the BOX layer, and the crystalline SiO_2 exists not only close to the interfaces but distributes also in the whole part of the BOX layer. The structure factors for the β-cristobalite model [1] and the tridymite model [2] were calculated, which have been proposed for the crystalline transition layer at the interface between thermal oxide and Si substrate. The extinction rule for the β-cristobalite model completely disagreed with the present measurements, while the structure factors for the tridymite model partially agreed.

P06.11.022 STRUCTURAL CHANGES DURING A TYPE CONVERSION ANNEAL OF CDS-CDTE HETEROJUNCTION SOLAR CELLS. K.D.Rogers and D.W.Lane and J.D.Painter and D.A.Wood, Department of Materials & Medical Sciences, Cranfield University, Shrivenham, Swindon, Wilts. SN6 8LA U.K.

Second generation, thin film solar cells based upon CdS-CdTe heterojunctions are becoming a viable alternative to silicon based technologies. Cell efficiencies depend upon the nature of structures formed during deposition and any subsequent processing, e.g. an essential type conversion anneal.

We have undertaken an extensive examination of the as-deposited CdS-CdTe structures and their response to heat treatments. Principally, a combination of X-ray diffraction and Rutherford backscattering spectrometry has been applied to samples consisting of electrodeposited and PVD CdTe (~2.0 μm) supported upon CdS (<0.1μm). We have developed novel methods of depth profiling using a chemical bevel process that has enabled us to determine structural characteristics through the films.

The results show that the annealing causes the formation of intermixed regions consisting of $CdTe_{(1-x)}S_x$ and $CdS_{(1-y)}Te_y$ which modify the spectral response of the final device. Using synchrotron techniques, the formation process is mapped dynamically to reveal details of a recrystallisation process that occurs in association with the interdiffusion. Further, we demonstrate that the extent of the intermixed region is mediated by the initial, as-deposited structures rather than system thermodynamics. Implications for the control of the extent of this non-stoichiometric region through changes to fabrication parameters are discussed.

P06.11.023 IN-SITU RADICAL BEAM OXIDATION OF MBE-Si GROWN ON A HYDROGEN TERMINATED Si(111). M. Umeno, Y. Yoshioka, T. Muta, K. Mizobata and T. Shimura, Department of Material & Life Science, Osaka University, Suita, JAPAN.

Thermal oxidation is a significant key process of the Si LSI technology and the vast amount of researches on Si-SiO_2 systems have been done. Recently, existences of some crystalline oxide phases in the thermal oxide layer on Si wafers have been ascertained [1]. It is found that the structure of the crystalline phase depends on the orientation of the substrate wafer and that their amount seems to closely relate to the electrical properties of the oxide film. The fact that the oxide films with the higher C-mode break down ratios contain the more crystalline phase might indicate that the understanding of the crystalline SiO_2 phase is useful to develop new oxidation processes.

We performed an oxidation experiment with the extremely ideal atomically flat Si surfaces prepared by the molecular beam epitaxy (MBE) method, in which we adopted the hydrogen termination by dipping into the NH_4F solution for the surface cleaning as well as to obtain atomically flat Si(111) surface. When the specimen was heated in UHV, the (111) surface structure changed from the initial 1×1 at room temperature to the $\sqrt{3}\times\sqrt{3}\,R30°$ at about 600°C and then to the 7×7 at 700°C. The epitaxial silicon layers were easily formed on the 7×7 surface at 750°C keeping the same surface. The monitoring of the surface structures and the film thickness were done with an ellipsometor as well as with the RHEED method. It was found that the polarizing parameters Δ and ψ in ellipsometry showed oscillations during the MBE growth. The oscillation periods were not the same as that of the RHEED oscillation, indicating the measurement of different information of the surface irregularities at the same time. The oxidation of the MBE silicon was performed in the chamber connected to the main MBE chamber without exposing to any environments before the oxidation process at relatively lower temperatures than usual case using a radical O_2 beam or with an O_2 atmosphere.

P06.11.024 THE HRXRD INVESTIGATION OF THE LATERAL CHEMICAL COMPOSITION DISTRIBUTION IN SUPERLATTICE CRYSTALS. Jarek Gaca, Marek Wojcik, Institute of Electronic Materials Technology, Warsaw, Poland.

The most distinctive feature of the superlattice crystal (SL) is that the periodic variation of its chemical composition occurs only in the growth direction. The homogeneity of the composition in the lateral directions is achieved by placing the substrate crystal on a stage that is rotated during the deposition process. However if the rotation speed is too slow or the flow of the gases is not properly controlled then there may appear additional variation of the composition (lateral composition gradient - LCG). In this case it is not possible to characterise the chemical composition profile in the whole volume of the crystal by one composition modulation wave.

In order to describe the SL crystal in which there exists a composition gradient it is assumed that this crystal can be divided into domains. Each domain is considered to be an ideal SL crystal, fully characterised by a one composition modulation wave. Neighbouring domains differ in that they are characterised by different chemical composition modulation wave. In order to fully characterise the SL crystal with LCG, it is necessary to apply so many independent waves as there are domains. The introduced division is an approximation to the real structure of the SL crystal and is quite arbitrary. It serves only to facilitate the calculation of the diffraction profile from the SL crystal with LCG. So the sizes of the domains can be chosen so that they make a system of weights providing the probability that the domain characterised by a given composition modulation wave appears in the crystal.

In case of single domain the knowledge of the chemical composition of each atomic plane makes it possible to calculate the planar scattering abilities and due to Vegard law the separation between the atomic planes. Hence using the kinematical diffraction theory the scattering amplitude can be calculated. The scattered intensity from the SL crystal with LCG is calculated assuming that the incident beam is diffracted independently by each domain. The error made by this assumption is in most cases negligible.

To investigate the influence of the LCG on the diffraction pattern two InGaAs/InP SL samples were grown by MOCVD technique on the 001 InP substrate. One sample was rotated during the growth process to ensure its homogeneity, the other one

was not rotated in order to introduce the intentional LCG. The samples were measured by applying the θ/2θ scan mode with the diffraction vector parallel to 001 growth direction.

It was shown that the X-ray diffraction profile from SL crystal with a LCG is modified in comparison to that from an ideal SL crystal. The satellite reflections show characteristic broadening related to the variation of the modulation period. Computer simulation of the diffraction profile based on the domain model allows to determine the profile of the LCG in the SL crystal. It was shown that the LCG causes the variation of the modulation period, which may be brought about by the variation of the number of atomic planes and/or by the changes in their chemical composition.

P06.11.025 MICROSTRUCTURE, CHEMICAL COMPOSITION, AND ELECTRICAL CHARACTERISTICS OF ZnO THIN FILMS. J.H. Choi, and B.J. Kim, Dept. of Materials Sci. and Engineering, Inha University, Inchon, Korea

402-ZnO and Al-doped ZnO thin films were prepared by rf magnetron sputter techniques. The effect of substrate temperature, sputter gas, surface sputter, and post-deposition heat-treatment on the microstructure, surface morphology, chemical composition, and electrical characteristics of the films were investigated with sputter gas of pure argon as well as at room temperature with sputter gas of a mixture of argon and oxygen exhibit a strong tendency of 002 preferred orientation. The thin films with 002 preferred orientation has a chemical stoichiometry of Zn/O=1.01, a band gap of 3.3 eV, and a packing density of 98%, respectively. When a particular content of Al is doped, the crystallinity, surface flatness, and electrical conductivity of the films increased significantly. The films, which were annealed at various atmosphers, exhibit sheet resistance ranging from a few charge carrier concentrations of and optical band gap of 3.2 to 3.6 eV. When the surface of the film was sputtered at particular conditions, the surface area was increased, making the films more sensitive to heat-treatments at particular atmospheres

P06.11.026 STRUCTURAL PROPERTIES OF NANOCOMPOSITE THIN FILMS CONTAINING MAGNETIC NANOPARTICLES. O.Nittono, A.G.Roy, M.Azumi, M.Wakamori, Y.Haga and Y.Nakamura, Department of Metallurgy, Tokyo Institute of Technology, Meguro-ku, Tokyo, Japan

In this study nanocomposite films such as carbon and aluminum nitride(AlN)thin films contaning transition metals and carbides were prepared by a codeposition technique of metal and carbon, and also by a reactive sputtering deposition using composite targets such as Al-Fe, Al-Co and Al-Fe-Co, and nitrogen gas as sputtering gas. Magnetic and electrical properties of such films were investigated with respect to microstructures of the films subjected to various annealing conditions. Microstructures as well as phase stability including phase decomposition and cystallization in the films were evaluated by X-ray diffraction and by electron diffraction- transmission electron microscopy. Main results are as follows:(I)Carbon films: Transition metal carbides such as Ni3C, Co2C and Co3C were found to be formed easily under special deposition conditions where kinematical reactions are thought to take place easily. Microstructures of as-deposited films were strongly dependent on the gas flow of carbon. The films were composed of metal and/or carbide nanoparticles, amorphous carbon and graphite. Such nanoparticles were embeded in the matrix film. The films showed positive or negative thermal coefficients of resistivity depending on the distribution state of nanoparticles in the composite films. Decomposition processes of these metal carbides were found to be well interpreted based on the equilibrium phase diagrams taking account of decarbonization out of the film. Graphite particles were seen to grow through the metal mediated crystallization process for these carbides. (II) AlN films: As-deposited films appeared amorphous-like depending on the content of metal, and after annealing metal nanoparticles such as Co and Fe precipitated from the matrix film which is supersaturated with metals, and then decomposed, although the crystal lattice of AlN was not recovered completely even after annealing at 800K. No cobaltnitride was formed, but ironnitrides were easily formed at the initial stage of sputtering, then decomposed into iron particles at higher temperatures. When the content of iron increased, FeAl alloys were formed, which did not show ferromagnetism. Magnetic properties were invesigated in terms of microstructures during annealing process. Finally we summarized common features of structural properties for such nanocomposite films.

P06.11.027 STRUCTURAL CHARACTERIZATION OF VACUUM EVAPORATED THIN FILMS OF ZnSe. Pradip Kr. Kalita,B.K.Sarma, H.L.Das Department of Physics, Gauhati University, Guwahati-781014, Assam, India

X-ray diffraction pattern of thin films of ZnSe deposited by vacuum evaporation at substrate temprature within the range 303K to 623K have been recorded for the study.All ZnSe thin films were found to be of pollycrystalline nature have f.c.c cubic zincblende structure irrespective of substrate temperature (Ts) and thickness .The grain size, microstrain,average stress, dislocation density and degree of orientation have been estimated. It is observed that grainsize increases with Ts whereas average stress, microstrain,dislocation density decreases with Ts . Attempt is made to correlate the structural variations with photosensitivity of the films.

P06.11.028 CRYSTALLINE PROPERTIES OF Al\\Al_2O_3 MULTILAYERS. C. Malibert, C. Le Paven-Thivet, Ph. Houdy, LMN, Université d'Evry Val d'Essonne, bd F. Mitterrand, 91025 Evry Cedex, France.

Materials based on multilayers have became of great interest in recent years, due to the improvement of physical properties of such systems compared to single layers or bulk materials. Interesting physical properties can be achieved by the complementarity of the two materials [1]. Enhancement of wear-resistance mechanical properties can be achieved in different composites systems, like Ti/TiN [2] and Al/Al_2O_3 [3,4] multilayers.

In this work, crystalline properties of these nanoscale Al/Al_2O_3 system have been studied by X-ray diffraction and reflectivity. They have been correlated to morphological and chemical properties (characterized by MEB and SIMS), as well as mechanical properties.

Al/Al_2O_3 multilayers have been deposited by reactive rf-sputtering onto (100) sicilon wafers, for substrate temperature T_S ranging from –90°C to 600°C, and also with different period thickness. Polycrystallised aluminium films exhibit a rough surface, with grain size increasing with substrate temperature whereas alumina films are amorphous, with smooth surface. Although multilayers present a granular surface, X-ray reflectivity patterns show Bragg peaks, typical of multilayers character. This character depends on T_S temperature, on the roughness of aluminium layers and the existence of interfaces.

P06.11.029 DEPTH-RESOLVED DETERMINATION OF SHORT-RANGE ORDER OF IRON IN FE/AL MULTILAYERS. D.C.Meyer [1], P.Gawlitza [2], T.Holz[2], K.Richter [1], P.Paufler [1]. [1] Institut f.Kristallographie u. Festkoerperphysik der TU,D-01062 Dresden, Germany. [2] Fraunhofer-Institut f.Werkstoff- u. Strahltechnik Dresden, D-01277 Dresden, Germany

A multilayer consisting of 4.6nm AlOx , 1x 12.3nm Al, 6 x (4.3nm Fe + 10.4nm Al) as obtained by Pulsed Laser Deposition has been investigated using a combi- nation of X-ray absorption fine structure , X-ray reflectometry and X-ray standing wave techniques at the HASYLAB Hamburg. According to this the average Fe atoms were found to be surrounded by 8.1 Al atoms and 5.9 Fe atoms (nearest plus next-nearest neighbours),respectively, while the structure retained of the tungsten type. Formation of a CsCl type phase could be excluded. For the Al/Fe interface an Al content lower than 47% Al has been evaluated, whereas the corresponding figures near the Fe/Al interface came up to 6.6 Al and 7.4 Fe. The difference is obviously due to a kinetic intermixing effect.

P06.11.030 POLYIMIDE LANGMUIR-BLODGETT FILMS BASED ON THE DIFFERENT PREPOLYMERS V.V.Klechkovskaya, N.D.Stepina, I.A.Fedorinin and L.A.Feigin [1], V.P.Sklizkova and V.V.Kudriavtsev [2], [1] Electron Diffraction and Small Angle Diffraction Laboratories, Institute of Crystallography, Russian Acad.Sci., Moscow 117333, Russia, [2] Laboratory of Polyimides, Institute of Macromolecular Compounds, Russian Acad.Sci., St.-Petersburg 199004, Russia

Mono- and multilayer Langmuir-Blodgett (LB) films of rigid-chains polyimide prepolymers (the amphyphylic derivatives of polyamide acid PAA) have been studied. Among those are: 1) hexadecyl ester of PAA based on the 4,4`-diaminodiphenyl ether and pyromellite dianhydride, 2) alkyl-ammonium salt of PAA based on the dianhydride of 3,3`,4,4`-diphenyltetracarboxylic acid and o-tolidine (PAA-C16). The influence of solvent composition on the structure of LB-films has been investigated. The dependence of structure ordering on the preparation technique (casting on glass or Langmuir-Blodgett method) has been revealed.

Diluted solutions of PAA-C16 in a mixed solvent consisting of N,N`-dimethylacetamide and benzene in a ratio 50:50 were studied. The formation of associates of fluctuative origin was observed. The associates possessed a microanisotropic structure. The formation of perfect and homogeneous films occured only in a freshly prepared solution of PAA-C16 salts. The optimal solution concentration for the ordered packing of intramolecular fragments in monolayer was determined.

This work was financially supported by Russian Foundation for Basic Research, Grant No 98-03-33427a.

P06.11.031 X-RAY STRUCTURE OF SIGE/SI SUPERLATTICE INTERFACES GROWN ON VICINAL SI(111) SUBSTRATES Y. Yamaguchi and H. Hashizume [1], J.H. Li [2], [1] Material. and Structural. Lab., Tokyo Inst. Tech., Yokohama 226-8503, Japan, [2] Inst. of Phys., Chinese Acad. Sci., Beijing 100080, PRC

Si(1-x)Ge(x)/Si superlattices grown on vicinal Si substrates show low-angle x-ray diffuse scattering arising from random and periodic interface roughness. The periodic component is due to the arrayed atomic steps at the SiGe/Si interfaces, replicated from the substrate surface, of which terrace width and step height distribute around the mean values. The mean structure gives rise to Bragg-like peaks near the specular peak. To simulate complicated diffuse pattern in 2D reciprocal space, we developed a formulation using the distorted-wave Born approximation, which allows us to determine the height-height correlation functions for the random and periodic roughness simultaneously. The formulation explains well the very different x-ray diffuse patterns observed from two samples with 0.1 and 0.3 for x, grown on 0.6 degrees offset Si(111) substrates with other multilayer parameters quite similar. We will present the interface structures of these two samples revealed by applying our formulation, with discussion on the role of lattice strain on the different interface structures.

P06.11.032 TECHNOLOGICAL PECULIARITIES OF FORMATION AND QUALITIES OF THIN FILM COATINGS ON THE BASIS OF FLUORINE-CONTAINING POLYMERS AND OLIGOMERS. Yu.S. Boiko, V.A. Struk, Physis & Ingineering Departament of Grodno State Uneversity, Ozheshko st. 22, Grodno 230023, Belarus.

The subject of study is thin films on the basis of polytetrafluorinethylene and fluorine-containing oligomers. The aim of the prezent paper is the investigation of physical and chemical aspects and technological peculiarities of the formation of thin coatings on the basic of fluorine-containing polymers and oligomers on the friction surfaces and their influence on the operational parameters of metal-polymers tribosistems. In the terms of relaxation diflysion theory of interphase processes the phenomenological model was developed for the formation of thin film coatings from the active phase on the solid surfaces of various nature. Analytical expressions of active fragments distribution in coatings' depending from the structure of metal-polymer systems and technological factors of formations were acquired. The influence of technological factors (temperature, medium, energy influens doses, solutions concentration) on the structure and properties of fluorine-containing polymer and oligomer films on the metals and non-metals was established. The technological regimes of formation of films with the given adhesive and cohesive durability were defined. The complex investigations of operational, including tribotechnical, properties of oligomer films in metal-polymers systems were ander taken. The peculiarities of providing ofhydrophobic, anti-oxidant and anti-wear effect of thin films on non-metallic substances depending on their structure and formation technology were established. The experimental industrial testing of the effeciency of application of thin film coatings from fluorine-containing polymers and oligomers in tribotechnical and tennoregulated systems structures was carried out. The economical effect from the application of the working out of the problem was considerable.

P06.11.033 3-D STRUCTURE OF MIXED $Sr(Ca)CuO_2$ and $BaCuO_2$ SUPERLATTICES EPITAXIALLY GROWN ON $SrTiO_3$. S. Harkema, G.J. van Hummel, G. Koster, A.J.H.M. Rijnders, D.H.A. Blank and H.Rogalla, Low Temperature Division, Dept. of Applied Physics, University of Twente, P.O.Box 217, 7500AE Enschede, the Netherlands.

In our laboratory a method has been developed to prepare singly terminated $SrTiO_3$ surfaces of high quality [1]. The $SrTiO_3$ surfaces prepared this way are ideally suited for the layer by layer growth of epitaxial layers. A number of layers consisting of alternating blocks of different size of composition $(Sr(Ca)CuO_2)_n$ $(BaCuO_2)_m$ has been prepared by Pulsed Laser Deposition.

The quality of the layers (thickness 50nm) is such that single crystal like methods can be used to determine their structure. Results for the 3-dimensional structures of these layer systems will be presented.

P06.11.034 MAGNETIC PROPERTIES OF V OVERLAYERS ON THE (100) AND (110)W SURFACES. S. V. Man'kovsky G. V. Kurdyumov Inst. for Metal Physics of N.A.S.U, 36 Acad. Vernadsky Blvd., UA-252680 Kiev-142, Ukraine

The magnetic properties of V overlayers on the (100) and (110)W were studied using full-potential LAPW method. The features of electronic structures for different crystallografic planes and the effects of surface relaxation are studied. The total energy calculation for one V monolayer on the (100) W surface predicts the nonmagnetic ground state of this system. However, there was found ferromagnetic ordering in V overlaers for the 2V/ W (100). The role of hybridisation of V d-states with W d-states in ground state formation is analysed.

P06.11.036 GALVANO-MAGNETIC PROPERTIES OF AMORPHOUS THIN FILMS OF TRANSITION METALS. S.A. Lebedinskiy, O.A. Kordin and Yu.V. Barmin, Dept. of Solid State Physics, Voronezh State Technical University, 394026 Voronezh, Russia.

Amorphous Re - T_{3d} alloys were prepared by high rate sputter deposition of composite target as a substrateless foils 10 - 15 μm. The composition of alloys was determined by electron-probe microanalysis method with 0,5 at. % accuracy.

The temperature dependence (4,2 - 300 K) of the Hall coefficient $R_H(T)$ in amorphous Re - T_{3d} alloys have been measured. The anomaly (deep minimum) of $R_H(T)$ dependence in Re-Cr alloys have been observed, with the absence of it in the case of Re-Nb. The temperature of this anomaly is increased with increasing the concentration of Cr atoms.

To reveal the nature of this effect the complex of low-temperature measurements of galvano-magnetic properties have been done: magnetoresistance ρ(H), electrical resistivity ρ(T), ac susceptibility χ(T) and dc magnetization M (T).

P06.11.037 MAGNETIC STRUCTURES OF METAL MULTILAYERS BY RESONANT X-RAY MAGNETIC SCATTERING. H. Hashizume, N. Ishimatsu, S. Miya, Y. Yamaguchi [1], N. Hosoito [2], G. Srajer, C. Venkataraman, J. Lang, C. Nelson [3], [1] Materi. and Struc. Lab., Tokyo Inst. Tech., Yokohama 226-8503, Japan, [2] Inst. for Chem. Res., Kyoto Univ., Uji 611-0011, Japan, [3] APS, Argonne Nat. Lab, IL 60439, USA

We report the magnetization structures of a few metal multilayers determined by measuring resonant x-ray magnetic specular reflections with circular polarized probing x-rays at synchrotron sources. The technique is element specific and allows us to determine the depth-dependent strengths and spatial orientations of local magnetic moments with respect to the applied in-plane field at few Angstroms resolutions. In case of a [Fe(3.5nm)/Gd(5.4nm)]15 multilayers, we have confirmed for the first time the phase change in the Gd layers between the aligned and twisted states. The Gd layers nearly fully magnetize at the Fe/Gd interfaces even at RT, whereas the central sublayers show spontaneous magnetizations below 240 K, suggesting a Curie temperature much lower than that for bulk Gd. The twist angles of local Gd moments show interesting behaviors as a function of temperature. Results for Fe/Dy, Fe/Cr multilayers and NiFe/SmCo bilayers will also be reported. Furthermore, magnetic roughness at the Fe/Gd interface will be discussed in reference to magnetic diffuse scattering measurements made on the Fe/Gd sample.

P07.11.001 X-RAY STUDY OF ELLIPTICINE INTERACTION WITH MODEL MEMBRANES. I.L. Torriani and L.P. Cavalcanti, Instituto de Física, Universidade Estadual de Campinas, C.P.6165, 13083 Campinas, SP, Brazil and C.R. Zacharias, UNESP, Guaratingueta, SP, Brazil.

For almost two decades, ellipticine (5,11-dimethyl-[6H]-pyrido[4,3-b]-carbazole) (ELPT) and some of its derivatives have been known to posses cytotoxic effects and have been tested as antitumor agents in human cancer cells. Ionic and hydrophobic interaction of ELPT molecules with natural and model membranes has been investigated in experiments with phospholipid multilayered vesicles, suggesting that the interaction was stronger in the case of negatively charged lipids [1]. These molecules have a quasi planar structure and a highly hydrophobic nature, so they are expected to occupy some position in the membrane hydrophobic region. For most of our experiments single component or mixed multilayered liposomes of Dipalmitoyl Phosphatidyl Choline (DPPC) and Cardiolipin (CL) were used as a host for ELPT intercalation. The samples were prepared in several molar ratios to obtain a single phase and stable lipid bilayer structure, producing low angle X-ray diffraction patterns with up to eight lamelar reflections. ELPT was added to DPPC and mixed DPPC:CL samples in gradually increasing ratios, until X-ray reflections from the crystalline form of ELPT were detected. This was a way of monitoring incorporation of the drug in the membrane and the perturbation produced in its structure. Several pH values for the aqueous media were also used, to test incorporation of the protonated form of ELPT. Changes in the host bilayer structure can be observed in the electron density profile maps calculated for the DPPC:ELPT and DPPC:CL:ELPT multilayer systems. Since encapsulation of ELPT reduces its toxicity [2], these results are relevant for the design of an adequate drug carrier.

P07.11.003 THE USE OF MULTIPLE SCATTERING TO ENHANCE SANS EXPERIMENTS. T M Sabine and W K Bertram, Materials Division, Australian Nuclear Science and Technology Organisation, Menai, NSW 2234, Australia

Multiple scattering of neutrons by the inhomogeneities responsible for small angle scattering during the passage of the beam through the specimen can be used to provide valuable information about the shape of the objects, and the absolute value of the contrast between the scattering particles and the matrix.

The neutrons that emerge from the specimen are classified according to the number of times, n, they have been scattered during their passage through the specimen. The values of n range from zero to infinity. The remnant of the incident beam is that component for which n = 0. Depletion of the incident beam during its passage through the specimen is taken into account.

Each group contributes separately to the scattering profile. The cross-section for scattering into the small angle region is independent of the neutron wavelength only for n = 1. Thus collection of data as a function of specimen thickness, and of neutron wavelength will provide a number of different diffraction profiles describing the same physical situation.

It is shown that SANS patterns from specimens which are of different thicknesses, but are otherwise identical, not only provide information on the shape and size of the scattering entity but also provide absolute values of the scattering contrast between the particles responsible for SANS and the matrix. No separate calibration of the incident beam is required.

This method of analysis is applied to SANS data on hydrated cement paste. The data was collected on the Ultra High

Resolution SANS Diffractometer at Oak Ridge National Laboratory, USA.

P07.11.004 NEUTRON DIFFRACTION AND SANS IN HIGH-NITROGEN Fe-19Cr-19Mn-0.9N AUSTENITE. V. M. Nadutov [1], V. M. Garamus [2], A.Ch. Islamov [3], [1] G. V. Kurdyumov Institute for Metal Physics of the Academy of Sciences of Ukraine, Kiev, Ukraine, [2] Frank Laboratory of Neutron Physics, Joint Institute for Nuclear Research, Dubna, Russia & GKSS Research Centre, Max Plank Strasse, Geesthacht 21502, Germany, [3] Frank Laboratory of Neutron Physics, Joint Institute for Nuclear Research, Dubna, Russia

The purpose of the present work is to examine a structure and a solid solution state of nitrogen-containing Fe-19%Cr-19%Mn-0.9%N (wt %) austenite after solution treatment at 1125oC and water quenched and then ageing treatment at 250-350oC. The high-nitrogen steel was studied by means of neutron diffraction and small-angle neutron scattering (SANS). The neutron diffraction experiment was carried out on the DN-2 time-of-flight instrument and the measurements of SANS were performed using 'MURN' time-of-flight small-angle neutron scattering spectrometer at the IBR-2 pulsed reactor at the Frank Laboratory of Neutron Physics, Joint Institute for Nuclear Research, Dubna, Russia.

The neutron diffraction measurements show a single-phase austenitic state after annealing of the steel. A change of the diffraction peak position and line width is not observed after ageing treatment.

SANS is observed both in as-quenched and age-treated samples. The analysis within Guinier and Porod approximation has shown that SANS is attributed to inhomogeneities. They are characterized by non-spherical shape. The estimated average size of the inhomogeneities is approximately 200 Å. The contrast of the inhomogeneities decreases under ageing that we attribute to atomic redistribution in austenite.

P07.11.005 SMALL ANGLE X-RAY SCATTERING REVEALS CONFORMATIONAL AND OLIGOMERIZATION FORM CHANGES IN PIG S100A12. M.C.Nonato, W.P.Jesus, S.A.Sculaccio, R.C. Garratt, G.Oliva [1], C. Barberato [2], C. Schleicher, J. A. Santomé [3], [1] Laboratório de Cristalografia de Proteínas e Biologia Estrutural, Instituto de Física de São Carlos, São Carlos, Brazil, [2] Departamento de Informática, Faculdades Associadas de São Paulo (FASP), São Paulo, Brazil, [3] Instituto de Química y Fisicoquímica Biológicas, Universidad de Buenos Aires, Argentina.

The S100 family consists of small acidic proteins, belonging to the EF-hand class of calcium-binding proteins. They are primarily regulatory proteins, involved in cell growth, cell structure regulation and signal transduction. p-S100A12 is a member of the S100 family extracted from pig granulocytes, which has been shown to bind not only calcium but also zinc ions, as already observed for other members of the same family. Small Angle X-ray Scattering experiments were performed for p-S100A12 solutions in four different metal binding conditions: the apo, Ca^{2+}, Zn^{2+} and $Ca^{2+}Zn^{2+}$ forms. The differences in the scattering curves show that p-S100A12 undergoes conformational changes in the presence of calcium ions and increases its oligomerisation state upon addition of zinc ions. The results corroborate the suggestion that Ca^{2+} and Zn^{2+} ions bind to different sites. We propose here that p-S100A12 may have two different functions in the immune system according to the ion binding, as an intracellular regulatory Ca^{2+}-binding protein and as part of an anti-microbial host defence system via Zn^{2+} binding dependent.

P07.11.006 EFFECT OF X-RAY ANOMALOUS DISPERSION ON SMALL ANGLE SCATTERING OF Cu IONIZED NIPA-GEL. S. Kuwajima, Y. Soejima, M. Sugiyama, Department of Physics, Kyushu University, Fukuoka 812-8581, Japan, K. Hara, Faculty of Engineering, Kyushu University, Fukuoka 812-8581, Japan, A. Nakamura, N. Hiramatsu, Faculty of Science, Fukuoka University, Fukuoka 814-0133, Japan, and A. Suzuki, Faculty of Engineering, Yokohama National University, Yokohama 240-0067, Japan

The relation between the size of gel molecules and that of adsorbed metal ions of N-isopropyleacryleamide (NIPA) gel containing Cu ions has been investigated. The intensity of small angle scattering as a function of incident X-ray energy around Cu K absorption edge has been measured at PF, Tsukuba. The intensity variation due to the anomalous dispersion of Cu ion is observed only in the momentum region around 0.30 nm^{-1}, where the scattering peak corresponding to the formation of gel molecule clusters is observed. The results show that the size of the clusters of adsorbed Cu ions is of the same order of magnitude as that of the cluster of gel molecules. This supports, at the same time, the idea that the metal ions are adsorbed into the cluster structure of the gel molecule. It is confirmed that there is no other momentum regions where the intensity varies as a function of incident energy, and, consequently, that the cluster of metal ions is formed only in this size. Moreover, measurements have been made of the gel without Cu ions; the intensity peak is observed at 0.23 nm^{-1}. The results indicate that the size of the cluster of gel molecule is larger than that in the case of gel containing Cu ions.

P07.11.007 SMALL-ANGLE NEUTRON SCATTERING STUDY OF *BOMBYX MORI* CYTOPLASMIC POLYHEDROSIS VIRUS. M. Sato, Graduate School of Integrated Science, Yokohama City University, 22-2 Seto, Kanazawa-ku, Yokohama, Japan and T. Hasegawa, Institute for Protein Research, Osaka University, 3-2 Yamada-oka, Suita, Osaka, Japan and M. Nagao, Neutron Scattering Laboratory, Institute for Solid State Physics, University of Tokyo, 106-1 Shirakata, Tokai, Naka, Ibaraki, Japan and M. Tomita, Department of Chemistry for Materials, Mie University, 1515 Kamihama, Tsu, Japan

Silkworm *Bombyx mori* Cytoplasmic Polyhedrosis Virus (BmCPV), a genus of the Reoviridae, consists of ten dsRNA segments and polyhedrin that forms occlusion bodies, and forms a very large particle of a biological supramolecular complex with a molar mass of about 10^8. The overall and internal structures of BmCPV was investigated by small-angle neutron scattering (SANS) using the contrast variation method.

The SANS experiments were carried out by SANS-U, installed at C1-2 beam port of the JRR-3M reactor of JAERI at Tokai, Japan. SANS data were collected in aqueous buffer solutions containing 0%, 50%, 75%, and 100% D_2O in the q range of 0.002 to 0.0774 A^{-1} at 5 C. The radius of gyration at infinite contrast was estimated to be 336 A. The contrast matching point of the virus was determined to correspond to about 50% D_2O level, evidence that the virus is composed of protein and nucleic acid.

The virus particle was basically spherical and had a diameter of about 700 A. The main feature of the virus structure is the clustering of protein into two concentric shells separated by about 100 A. Most of the RNA moieties are located in the central core and between these two protein shells. However, the distance distribution function, P(r) showed the minor distribution beyond a distance of r = 700Å, resulting in 1350Å as the maximum particle

distance of the virus. This is indicative of the further existence of the external structure region, with very low scattering density, other than the basic spherical structure. This external region is thought to correspond to twelve pyramidal protruding spikes shown by electron microscopic studies.

P08.11.001 X-RAY REFLECTIVITY CHARACTERIZATION OF ARCHITECTURAL COATINGS ON GLASS. M. Eber and S.T. Misture, New York State College of Ceramics at Alfred University Alfred, NY 14802, USA.

Commercial thin film optical coatings on flat architectural glasses were characterized using specular and diffuse x-ray reflectivity. Low-emissivity coatings for thermal control containing up to five discrete thin films were investigated.

X-ray reflectivity was used to determine thickness, density, and interface roughness, while diffuse scattering was used to corroborate surface roughness. Secondary ion mass spectroscopy was used to confirm the chemical compositions of the optical thin films.

The surface of the glass itself, which is produced using the tin float technique, contains a Sn-rich layer with a low-density surface. Successful models required accurate descriptions of the surface of the float glass.

Multilayer coatings consisting of noble metals and oxides of zinc, titanium, and bismuth were characterized and correlated with the optical properties of coated glasses. Specifically, the normal-incidence optical reflectance could be calculated using the physical models determined from the x-ray measurements. Modifications of optical models for the materials were made which account for interface roughness, which is useful in designing film deposition strategies.

P08.11.002 CONSTRUCTION OF AN X-RAY REFLECTION SYSTEM FOR LIQUID-VAPOR INTERFACES USING AN IMAGING PLATE. Yohko F. Yano and Takao Iijima, Department of Chemistry, Gakushuin University, Toshima-ku, Tokyo, 171-8588, Japan

X-ray reflectivity measurements are now widely used mainly in the investigation of solid surfaces. Only a few groups have applied this technique to the study of liquid surfaces [1]. Most of those studies were performed using synchrotron radiation sources.

We have constructed an x-ray reflection apparatus for liquid-vapor interfaces using a conventional x-ray tube. The main features of our apparatus are as follows. Highly collimated and monochromated x-ray beams are generated using an asymmetrically cut Ge(111) crystal monochromater. An imaging plate, which has a high detective quantum efficiency, a low quantization noise and a wide dynamic range [2] is used as an area detector. The sample position is slowly elevated to compensate for evaporation during measurements. A device for surface tension measurement by the ring method is combined so that *in situ* measurements may be possible.

By measuring specular reflectivity, the vertical structural information such as the width of the liquid-vapor interface, namely, the root-mean square roughness can be obtained. From the nonspecular reflectivity (diffuse scattering), the horizontal structural information can be obtained as was formulated by Sinha *et al* [3]. In the case of liquid surfaces, the diffuse scattering can be represented by the height-height correlation function related to the surface tension [4].

By using an imaging plate, both of the specular and nonspecular reflection can be measured easily and simultaneously.

P08.11.003 DRASTIC DEFORMATION OF EPITAXIAL MICRO-CRYSTALS IN THERMALLY OXIDIZED LAYER ON ULTRA-THIN SI(001). I. Takahashi, S. Doi, R. Suetoshi, K. Ueda, T. Kada [1], N. Awaji, Y. Sugita, S. Komiya [2], [1]Advanced Research Center of Science(ARCS) Kwansei Gakuin University, Sanda 669-1337, Japan, [2]Fujitsu Laboratories Ltd., Atsugi 243-0197, Japan

Structure of oxidized Si layers on Si(001) wafers has remained the objects of intensive studies the past few years, because of their potential ability for VLSI technology in the 21st century. We have investigated the structure of various oxide/Si(001) interfaces by a complementary use of X-ray crystal truncation rod scattering and X-ray reflectivity. Throughout these researches, we have established the coherent micro-crystals distributed in the amorphous oxide. Subsequent studies revealed that the interfacial strain played an important role for stabilizing the micro-crystals. In the present work, we prepared thermal oxide layers grown on very thin Si films ranging from 100 to 2000 Angstrom so as to see the effect of the substrate on the micro-crystals, since part of the interfacial strain can be controlled by the thickness of the oxide and that of the substrate. Quantitative analyses of the diffraction data have successfully been performed. We will discuss in detail the existence of the novel critical thickness of the substrate which affects the relaxation process of the micro-crystals: if the thickness of the Si film is smaller than the critical value, novel relaxation process emerges where the micro-crystals can affect the local structure of the substrate. The process is also characterized by a drastic shrinkage of the crystal parameter of the micro-crystals along the surface normal direction; it shows a sharp contrast with the usual relaxation process where the micro-crystals always relax by expanding their dimensions.

P08.11.004 SCHILLER LAYERS IN β-FERRIC OXY-HYDROXIDE SOL AS AN ORDER-DISORDER PHASE SEPARATING SYSTEM. Yoshiko Maeda and Hideatsu Maeda*, University of Tsukuba, 1-1 Tennodai, Tsukuba, Ibaraki, 305 Japan, and *National Institute of Bioscience and Human-Technology, 1-1 Higashi, Tsukuba, Ibaraki, 305-8566 Japan

The structure and properties of Schiller layers in β-ferric oxyhydroxide (β-FeOOH) sol are studied by microscopic observation. The structure is determined to be smectic. Rod-like particles of β-FeOOH sol gather to form mat-like assemblies, in each of which the rods are packed with their axes nearly perpendicular to mat face. The mats are superimposed one on the other, to make up the whole structure. Two spatial periodicities in this structure would be the cause of the iridescence. This ordered structure coexisted in equilibrium with disordered suspension of the same sol. The Schiller layer systems usually have very low pH values (~ 2) and in these cases attractive interaction or the effect of the secondary minimum is eminent. However, at moderately low pH(~ 4), the interaction between the particles became repulsive, and, in spite of this, Schiller layers are formed when the sol is condensed to a certain extent. Formation of Schiller layers is a phase separation in monodisperse sol.

P08.11.005 GROWTH OF HIGHLY CRYSTALLINE SILICATE FILMS AT THE AIR WATER INTERFACE. J.W. White and A.S. Brown, S.A. Holt, P.A. Reynolds and J.L. Ruggles, Research School of Chemistry, Australian National University, ACT 0200, Australia.

The application of constrained refinement fitting to x-ray and neutron reflectometry data collected on self-assembled mesoporous silicate films growing at the air/liquid interface has been very successful [1,2]. The complementary nature of this method has enabled us able to follow the structure development from a simple surfactant surface excess through to a highly

crystalline mesoporous film thousands of layers thick. Recently we have begun work on the study of in-plane interface structure in these systems [3]. This presentation will give an outline of the background work and present data demonstrating the high degree of order in these self assembled systems.

P08.11.006 AN ATOMIC FORCE MICROSCOPY STUDY FOR ORDERED ASSEMBLIES OF ROD-LIKE MOLECULES FORMED ON GLASS SUBSTRATES.
Hideatsu Maeda, National Institute of Bioscience and Human-Technology, 1-1 Higashi, Tsukuba, Ibaraki, 305-8566 Japan

In highly concentrated systems of rod-like molecules, the onset of various ordered phases (dependent on molecular concentration and ratio of the molecular length to diameter) has been theoretically suggested and experimentally investigated by many workers.

We formed ordered assembly structures of tobacco mosaic virus (TMV) particles (300nm length and 15nm diameter) and monodisperse rod-like crystals of b-FeOOH (typically 350nm and 60nm diameter, although variable) on glass substrates, and examined their structures using atomic force microscope (AFM) and electron microscope.

For TMV suspensions with a concentration of 50 mg/ml, several characteristic ordered regions appeared, e.g., highly oriented regions in which the particles were uniaxially oriented, intermeshing side-by-side and interconnecting end-to-end. The critical bending angle of the individual TMV particles was also determined to be approximately 60 degrees.

12. FIBRE DIFFRACTION

P06.12.001 COMPARATIVE STUDY OF NORMAL AND ACID TREATED POLYESTER FIBRE BY SAXS , XRD, SEM AND INSTRON. T. Patel, S. Bal and B. Mallick, Department of Physics, R. E. College, Rourkela-769008 (Orissa), INDIA.

Physical and Macromolecular properties of draw texturised fibre (DTF) of Polyester have been investigated applying Small Angle Scattering (SAXS) technique using the theories of Vonk[1] and Ruland [2] treating the fibre as an non-ideal two-phase system. Intensity data have been collected using compact kratky camera having counter device. The parameters obtained for normal and acid treated fibre are tabulated below where the symbols used in the table carry usual meaning.

Para-eters	ℓ_1 (Å)	ℓ_2 (Å)	r (Å)	c (Å)	e	E_v/D (%)	S/V	φ_1	φ_2
Original	40	8	3	28	.76	3	.006	.85	.15
Acid Treated	97	5	0	24	.77	2	.007	.84	.16

Crystallinity indices of the original and the treated sample have been calculated to be 25% and 23% respectively from their x-ray diffractogram. These samples contain crystallities of different sizes having orientations 1.45^0, 4.3^0, 3.875^0 and 1.6^0, 3.55^0, 4.35^0 with respect to their fibre axes. The fibre diameters estimated from SEM are 2100 Å and 2500 Å respectively. The percent elongation calculated from Instron vary between 10-20 % for original sample and 30-40 % for acid treated sample having corresponding Young's moduli $(31\text{-}52)\times10^8$ and $(19\text{-}20)\times 10^8$ N/m^2. The analysis of all the above parameters leads us to conclude that even strong acid (H_2SO_4) of pH 1 does not have much effect on the fibre at ambient temperature. Further analysis is in progress.

P06.12.002 NEUTRON STRUCTURE ANALYSIS AND STRUCTURAL DISORDER OF POLY(P-PHENYLENE BENZOBISOXAZOLE). Y. Takahashi, Department of Macromolecular Science, Faculty of Science, Osaka University, Toyonaka, Osaka 560, Japan.

On the X-ray fibre diagram of poly(p-phenylene benzobisoxazole) (PBO), the diffuse streak scatterings are observed along the first and third layer lines, while Laue spots can be observed on the second and fourth layer lines. This shows that the molecular heights of PBO are disordered by a half of the fiber period. Therefore, the cell parameter c reduced to a half of the fiber period, 12.05 ü. All the observed reflections can be indexed by the one-chain unit cell with parameters, a = 5.651Å, b = 3.570Å, c = 6.03Å, and $\gamma = 101.4°$ (at 295K) and the space group Pm.

Neutron diffraction has the several advantages in comparison with X-ray diffraction. The scattering length of hydrogen atom by neutron is larger than by X-ray diffraction and furthermore, the scattering lengths are independent of the scattering angle. Absorption of neutron by most elements is small in comparison with X-ray diffraction. Accordingly, the detailed crystal structure analyses of crystalline polymers can be carried out at low temperatures. Neutron diffraction measurements were made on the equator at 17K, 100K, 200K, and 295K, and the structure analyses were carried out. The half-widths of the reflections do not depend on the temperature. This shows that the crystallite size and lattice distortion are independent of the temperature. The R-factors converged to 9.9, 9.5, 13.1,and 12.1 % for the intensity data at 17K, 100K, 200K, and 295K, respectively. The azimuthal angle of the benzobisoxazole plane with respect to the a-axis is estimated to be 161.2° at 295K. The angle between the benzobisoxazole and the phenyl rings is 25.7° at 295K. The temperature dependences of the unit cell dimensions, molecular orientation, and temperature parameter are small in comparison with those of polyethylene, one of the flexible polymers. This may reflect the rigidity of the PBO molecule.

P06.12.003 AXIAL MOLECULAR PACKING OF FIBRILLAR TYPE I COLLAGEN. A HIGH RESOLUTION STUDY. J.P.R.O. Orgel, T.J. Wess, and I. Alberts, DBS, University of Stirling, Stirling. FK9 4LA, U.K. A. Miller, Principal's office, University of Stirling, Stirling, FK9 4LA, U.K. A. P. Hammersley, ESRF, BP 220 F-38043 Grenoble, Cedex, France.

The meridional Bragg reflections within the collagen type I diffraction pattern contain detailed information about the axial projection of collagen microfibrils. An unambiguous solution of the phase components of the structure factors combined with the measured amplitudes at high-resolution enables an accurate interpretation of the axial packing arrangement of fibrillar type I collagen.

Diffraction data has been recorded for the native protein and three highly isomorphus derivatives, using synchrotron radiation sources. The phase component of the structure factors has been calculated for 124 orders of diffraction through multiple isomorphus addition calculations to produce a high-resolution definition of the projected axial structure of collagen. This provides detailed information about the conformation of the non-helical telopeptides, the relative ratio of the gap/overlap period, and the axial alignment of the collagen molecules within the microfibril. The majority of previous studies of collagen structure have been negatively biased by their largely model dependent nature. Since in this study the phase components have not been calculated via a modeling approach, the results presented here should be seen as the most accurate to date.

P06.12.004 NEW STRUCTURAL MARKERS OF BREAST CANCER MEASURED USING SAXS. R.A. Lewis, CLRC, Daresbury Laboratory, Warrington, Cheshire, WA4 4AD, U.K., and K.D. Rogers, Department of Materials & Medical Sciences, Cranfield University, Swindon, Wilts. SN6 8LA, U.K. and C. Hall and E. Towns-Andrews and S. Slawson, CLRC, Daresbury Laboratory, and A. Evans and S. Pinder and I. Ellis Departments of Radiology & Histopathology, City Hospital, Nottingham, U.K. and C.R. Boggis' Manchester Breast Screening, Withington Hospital, Manchester, U.K. and A. Hufton Department of Medical Physics,Christie Hospital, Manchester, U.K.

Characterising the natural history of breast cancer is important for understanding associated biological mechanisms and for diagnosis. However, there have been few studies of the collagen structure associated with human breast tissue and, in particular, that of breast tumours. We report the findings of a study of breast tissue collagen that has investigated structural changes due to tumour genesis.

Small angle, synchrotron X-ray scattering data was collected on station 16.1 at the SRS, Daresbury using a camera length of 6.6m. Typical, 'core cut' biopsy specimens were provided both from patients and excised from reduction mammoplasty tissues. No specimen preparation was required. Radial integration of the 2-dimensional diffraction data enabled us to examine Bragg reflections and Bessel function peaks simultaneously.

We have found that, although both tumour and normal breast tissue collagens are of similar type (type I & III mix, D=64nm) their diffraction data is remarkably and consistently different. We demonstrate that there are significant structural differences between tumour and normal breast tissues with respect to supramolecular collagen architecture ; fibril ordering within the tumour tissues is almost absent. The data is supported by histopathological analyses that confirms the preponderance of collagen within all the specimens. The implications of these findings in the context of using molecular structure characteristics as new and novel markers of disease progression are discussed.

P06.12.005 WOOD FIBRE DIFFRACTION USING CCD DETECTORS IN FOREST PLANTING PROGRAMS. Renuka Kadirvelraj, Greg Smith and Ward T. Robinson, Department of Chemistry, and Ian D. Cave, Wood Technology Research Centre, University of Canterbury, Christchurch, New Zealand and Altaf Hussain, Department of Chemistry, Dhaka University, Dhaka, Bangladesh.

Strategies used to improve the mechanical properties of timber require a knowledge of the orientation of the constituent cellulose microfibrils present in the wood cell walls. Many methods like polarising, fluorescence and electron microscopy and iodine staining have been used to estimate the mean microfibril angle, which is the winding angle the cellulose microfibrils make with the cell wall. These methods are tedious and time consuming since the variability of biological material requires a large number of measurements in order to give meaningful average values. X-ray diffraction, using an area detector, produces a mean diffraction pattern from several thousand filaments in a single exposure and fast observation time. A diffraction pattern from wood recorded on an on-axis flat plate device such as an X-ray sensitive film or a CCD area detector consists of interrupted arcs on a set of concentric rings. These rings can be indexed as corresponding to the spacing of crystalline planes within the cellulose crystalline microfibrils. Analysis of the intensity distribution around these diffraction rings can give the mean microfibril angle (*mfa*) which is used as the predictor of stiffness of the wood sample. As the *mfa* decreases gradually from around 40 degrees in the pith to around 10 degrees in the cambium, the stiffness of the wood cell wall increases enormously. Thus *mfa* has important potential use in forestry planting and breeding programmes. There are many advantages in using wide angle X-ray diffraction techniques sensitive to the preferred *mfa* orientation and the speed of the area detectors in data collection makes large scale surveying of *mfa* possible.

P06.12.006 STRUCTURAL STUDY ON CHITOSAN/INORGANIC ACID COMPLEX. K. Noguchi, M. Kanenari, and K. Okuyama, Faculty of Technology, Tokyo University of Agriculture and Technology, 2-24-16 Naka-cho, Koganei, Tokyo 184-8588, Japan and K. Ogawa, Research Institute for Advanced Science and Technology, Osaka Prefecture University, 1-2 Gakuen-cho, Sakai, Osaka 593, Japan.

Chitosan, the N-deacetylated chitin, has received much attention as a functional biopolymer for its industrial and medical use. Since chitosan has a free amino group on each residue, it exhibits a remarkable ability to form specific complexes with a number of ions, inorganic and organic acids when immersed in their aqueous solution [1,2]. We have already analysed the crystal structures of the anhydrous [3] and the hydrated form [4] of tendon chitosan. Although several structural studies of the chitosan complexes have been attempted so far, none of the crystal structures have been analysed because of their complexity. Recently, we have found that certain chitosan/inorganic acid complexes can be obtained not only by immersing chitosan specimen in aqueous inorganic acid solutions, but also by exposing chitosan to their vapour. Among them, the X-ray diffraction pattern from the chitosan/HNO_3 complex obtained by the latter method (39 observed reflections) shows a better orientation and crystallinity compared with that obtained by the former method (22 observed reflections). All the observed reflections could be indexed in terms of an orthorhombic unit cell with dimensions of a = 9.63, b = 17.54, and c(chain axis) = 10.34 . The polymer chains take a 2-fold helical conformation and the unit cell contains four chains and eight HNO_3 molecules. The packing of molecules in this complex crystal is similar to that of hydrated chitosan [4]. Polysaccharide chains make a sheet structure parallel to the *bc*-plane. These sheets stack along the *a*-axis. HNO_3 molecules form columns between these sheets. Details of their molecular interactions will be discussed.

P06.12.007 FIBRILLIN: DIFFRACTION STUDIES OF AN ELASTIC PROTEIN. T.J.Wess [1], P.P. Purslow [2], C.M.Kielty [3]. [1] DBS University of Stirling FK9 4LA. [2] Meat science division KVL Copenhagen. [3] Department of Biological Science University of Manchester M13 9PT

Microfibrils are ubiquitous fibrillin-rich polymers which are thought to provide long-range elasticity to extracellular matrices, including the zonular filaments of mammalian eyes. The microfibrils appear in electron microscopy as beaded structures several hundred nm in length with a fundamental bead periodicity of around 56nm. The possible basis for elasticity of the tissue is based on the reversible changes in the beaded periodicity. X-ray diffraction of hydrated bovine zonular filaments (at the Daresbury Synchrotron) demonstrated meridional diffraction peaks indexing on a fundamental periodicity of ~56nm[1]. The effect of stretching the tissue up to 50% of the rest length had little effect on the position of meridional Bragg reflections, indicating a static population of bead lengths. The effect of extension up to 100% causes a deterioration of the diffraction signal and a weak fundamental peak can be observed at 84nm[2]. A Ca2+ induced reversible change in the intensities of the meridional Bragg peaks indicated that supramolecular rearrangements occurred in response to altered concentrations of free Ca2+. In the presence of Ca2+, the dominant diffracting subspecies were microfibrils aligned in an axial 0.33 D stagger. The removal of Ca2+ caused an overall enhanced regularity in molecular spacing, and the contribution from microfibrils not involved in staggered arrays became more dominant[3]. Simulated diffraction profiles and analyses of the staggered arrays of isolated microfibrils formed in vitro in the presence of Ca2+ were used to interpret the effects of Ca2+. These observations indicate how Ca2+ could modulate the organisation of individual microfibrils and three-dimensional arrays in vivo. This data allows a mechanism for elasticity at the molecular level to be related to the macroscopic tissue elasticity. Under the usual conditions of extension in the eye, bead periodicty changes in a discrete population along fibrils to facilitate elasticity. Molecular junctions of specifically staggered microfibrils maintain the integrity of the tissue and serve as anchors connecting the stretched microfibrils and allows the stored force to be transmitted through the tissue. The removal of Ca2+ enhances the regularity of the bead regions where stretching occurs and also allows the diffraction from unstaggered

beads to be observed.

P06.12.008 NONLINEAR ATOMIC PACKING AND THE THREE PHASE MODEL OF FIBROUS POLYMERS. Anuradha Mukhopadhyay, Department of Physics, Jadavpur University, Calcutta 700032, India and G.B.Mitra, Department of C.S.S., Indian Association for the Cultivation of Science, Calcutta 700032, India.

The simultaneous presence of three phases, viz the crystalline, the paracrystalline and the amorphous in fibrous polymers must be attributed to the long chain of atoms and the folding of these chains. Because of these folds, the atomic conglommerates tend to become crowded in parts and sparsely distributed in other parts. The sparsity of distribution is of varying magnitude. The atoms appear to be arranged on cylinders or conglommerates of coaxial cylinders. Along the axes of the cylinders, there will be equal slabs of atoms arranged equiangularly on concentric circles. The crystallinity is due to the equally spaced slabs along the axes of the cylinders. The paracrystallinity will be due to the circularly arranged atoms normal to the cylinder. The amorphosity is due to the random arrangement of atomic conglommerates in the matrix. In some variants, the circles may be replaced by ellipses while the axis of the cylinder may be slightly curved. These variants give rise to the diversity of the diffraction pattern. In the present work a mathematical analysis of these aspects has been developed.

P06.12.009 X-RAY STUDY OF STRUCTURE OF WOOD CELLULOSE IN NATIVE CONDITION AND AFTER VARIOUS PROCESSING. L.A.Lugovskaya, L.A.Aleshina, V.V.Petrova, M.V.Podoinikova S.V.Glazkova, A.D.Fofanov. Department of Solid State Physics, Petrozavodsk State University, pr. Lenina 33, 185640 Petrozavodsk, Russia.

An X-ray researches of structure has been performed and the data on the structural characteristics of samples of natural cellulose (bark, bast, early and late pine wood, raised in various ecological conditions and semifinished products received at first three work cycle stages of manufacturing of a paper) has been obtained. The samples were studies by an X-ray difractometer DRON-4 using Mo- Cu- and Fe-K_α radiations. The calculations of the experimental short-range order characteristics were carried out for amorphous components of cellulose by the Finbak method.

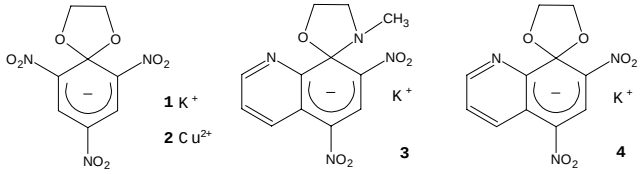
The sizes of the ordered areas and degree of crystallinity of samples for various orientations of a sample relatively of falling beams were determined. It is shown, that for a number of samples from native cellulose and samples received on the first production stages of a paper, is characteristic anisotropy of x-ray pattern. Besides in a matrix with the average size of coherence areas, equal 30-40 A, in natural samples and samples of semifinished products present in tens time larger ordered crystallites.

Largest diffuse of X-ray pattern of natural cellulose complicates the problem solving of indexing of the X-ray patterns and, as a consequence, correct estimation of the crystal lattice periods from diffraction data. In the given work the attempt was made to decide this problem by construction of model X-ray pattern, being based on the information on the atomic structure of unit cells of various polymorphic types of cellulose.

13. CHARGE, SPIN AND MOMENTUM DENSITY

P06.13.001 ELECTRON DENSITY DISTRIBUTION IN MEI-SENHEIMER COMPLEXES OF AROMATIC NITRO COMPOUNDS. O.Ya. Borbulevych, K.A. Lyssenko, M.Yu. Antipin, X-ray structural center, Institute of Organoelement Compounds, Russian Academy of Sciences, 28 Vavilov str., Moscow 117813, Russia, and O.V. Shishkin. SRD Alkali Halide Crystals, STC «Institute for Single Crystals», National Academy of Sciences of the Ukraine, 60 Lenina ave., Khar'kov 310001, Ukraine

An electron density distribution in the crystal of Meisenheimer complex — derivatives of 2,4,6-trinitrobenzole and 5,7-dinitro-quinoline **1-4** were studied using precision X-ray diffraction method at 153K.



Features of electron density distribution in organic anions (non-equivalent character of nitro groups and the C-C bonds within partially hydrogenated rings) have been revealed using Bader's topological theory. Molecular structure of various complexes of anions **1,3,4** — K^+ with different coordination of the cation to oxygen atoms has been calculated by high level *ab initio* methods.

Comparison of experimental and theoretical data have demonstrated that topological characteristics (e.g. bonds ellipticity) of electron density function within six-membered ring and nitro groups strongly depends on position of cation.

P06.13.002 BOND CHARACTERIZATION OF Cr–L MULTIPLE BONDS, L = C. N. O. Chih-Chieh Wang and Yu Wang, Department of Chemistry, National Taiwan University, Taipei, Taiwan, ROC.

Four chromium complexes with Cr–L (L = O, N, C) multiple bonds, are studied using ab-initio/DFT calculations based on the geometry obtained from single crystal X-ray diffraction data. They are $[Cr^{(I)}(CPh)(CO)_4(Cl)]$ **1**; $[Cr^{(V)}(N)(bpb)]$ **2**, [bpb^{2-} = (1,2-bis(pyridine-2-carboxamido)benzene)]; $[Cr^{(V)}$(N-*t*-Bu)(bpb)(Cl)] **3** and [(TPPOMe)$Cr^{(IV)}$O] **4**, [TPPOMe = (5,10,15,20-para-methoxyphenyl)porphyrin)]. Detailed descriptions of Cr–O_{oxo}, Cr–$N_{nitrido}$, Cr–N_{imido}, Cr–$C_{carbyne}$ bonds based the natural bonding orbital (NBO) analyses are presented. The bonding feature among these multiple bonds is essentially a triple bond character consisting of one σ and two π bonds. Bond characterisation will be shown in terms of Laplacian of electron density, Fermi-Hole function, electron localization function (ELF) where all the bonding information is embedded. The topological properties associated with the bond critical point (B.C.P.) of these four compounds will be compared. The relationship between bond order and the density (ρ_c) at BCP for various types of Cr–L bonds are well correlated based on theoretical comparison. The triple bond feature of Cr–$C_{carbyne}$, Cr–$N_{nitrido}$, Cr–N_{imido}, and Cr–O_{oxo} is displayed nicely by Fermi-Hole function. A comparison of such density distribution and topological properties between experiment and theory will be presented for compound **1** and **2**. The agreement between experiment and theory is encouraging.

P06.13.003 TOPOLOGICAL ANALYSIS AND CHARGE DENSITY STUDY OF OCTAAZA MACROCYCLIC Co(II) AND Ni(II) COMPLEX. Jey-Jau Lee and Yu Wang, Department of Chemistry, National Taiwan University, Taipei, Taiwan.

Accurate single crystal diffraction data are measured on $[Co(C_{12}H_{20}N_8)(H_2O)_2][ClO_4]_2$ crystal using MoKα radiation at 125K. It crystallises in the space group of P bca at 125 K. The final agreement index R is 0.033 and Rw is 0.037 based on 5547 observed reflections; the site symmetry of cobalt is at –1. Co(II) ion is co-ordinated in a square bipyramidal fashion with four immino-N at the equatorial plane and two water molecules at the axial positions. There are H-bonding between the cations and anions. Deformation density distribution based on the multipole model obtained experimentally is compared with those based on the HF and DFT calculations obtained theoretically. The agreement between experiment and theory is generally good. From NBO analysis, The bond between Co(II) ion and immino N is a dative bond and nitrogen atom is sp^2 hybridisation. Negative Laplacian around Co nucleus gives symmetric local density accumulation along x- and y- directions, which are at the bisection of N-Co-N angles. The C-C, C-N and N-N bonds of the ligand are all in covalent character and essentially a delocalised π-bond character. The theoretical electron density distribution and Topological analysis is also performed on the Ni(II) complex of the similar ligand, but the Ni(II) complex is in a four-co-ordinated square planar geometry. The orbital energies of Co d-orbitals in this complex is such that $E_{xz} \approx E_{yz} \approx E_{x^2-y^2} < E_z^2 < E_{xy}$. The Co(II) ion is in a low spin state with the singly occupied d_{z^2} orbital whereas the Ni(II) ion is doubly occupied on d_{z^2} orbital.

P06.13.004 THE OCCURRENCE OF NON-NUCLEAR MAXIMA OF THE ELECTRON DENSITY. V. Luaña, A. Martín Pendás, P. Mori-Sánchez, A. Costales, and M. A. Blanco, Departamento de Química Física y Analítica, Universidad de Oviedo, 33007-Oviedo, Spain.

Simple arguments and high quality quantum mechanical calculations are used to analyze the occurrence of non-nuclear maxima (nnm) [1] in the electron density of molecules and crystals. Rather than being a rarity, nnm are shown to be a normal step in the chemical bonding of homonuclear systems ... if analyzed in the appropriate range of internuclear distances. For most elements, however, this range occurs far away from the stable geometry under normal thermodynamical conditions. Heteronuclear combinations, on the other hand, behave quite differently, and nnm should only appear under exceptional circumstances. This discussion should contribute to the recent controversy over the experimental existence of nnm [2,3,4,5].

P06.13.005 PHOSPHONIUM YLIDE: THE CHARGE DENSITY STUDY AND *AIM* ANALYSIS. D.S.Yufit, J.A.K.Howard, M.G.Davidson, Department of Chemistry, University of Durham, Durham, UK DH1 3LE

The results of experimental determination of charge density distribution in molecule of phosphonium ylide Ph3P=CH-Ph (1) will be presented. For the best of our knowledge this is the first example of topological analysis of the experimental electron distribution in ylides. The data were collected at 100K on the Siemens SMART CCD 1K diffractometer and multipole refinement was carried out using XD [1] program package. Our experience of using CCD for charge density studies (data collection and processing) will be discussed. The bonding in (1) as well as intermolecular interactions in structure (1) is analyzed in terms of *AIM* [2] theory. Special attention is paid to parameters of C-H...C interactions that allegedly determine the packing of the molecules (1) in crystal.

P06.13.006 ANALYSIS OF XYLITOLS CRYSTAL CHARGE DENSITY. Anders Østergaard Madsen, Henning Osholm Sørensen and Sine Larsen, Centre for Crystallographic Studies, University of Copenhagen, Chemistry Laboratory IV, Universitetsparken 5, 2100 KøbenhavnØ, Denmark.

The crystal strucure of xylitol, $C_5H_{12}O_5$, in its stable orthorohombic form (space group $P2_1\,2_1\,2_1$) has been investigated earlier. It showed that the meso-pentitol xylitol in common with its diastereomer ribitol, has a non-planar conformation of the carbon chain, and that its five hydroxo groups are engaged in a complex pattern of hydrogen bonds. In order to elucidate the different intermolecular interactions of xylitol a new lowtemperature (122K) data collection was performed using MoKα radiation. The data extends to $(\sin\theta)/\lambda = 1.1 Å^{-1}$, R_{int} = 0.0219.

The multipole formalism for modeling of experimental electron densities is a well established method for the analysis of centrosymmetric structures, but has not been employed to the same extent to acentric space groups due to the latters lack of general phase restrictions. We report here our results from the multipole refinements for xylitol carried out using XD[2] and VALRAY[3]. The subsequent topological analysis of the experimental charge density is used to characterise the different intermolecular interactions found in xylitol.

P06.13.007 COMPARISON OF THE EXPERIMENTAL AND THEORETICAL CHARGE DENSITY OF *p*-FLUOROMANDELIC ACID. Henning Osholm Sørensen, Claus Flensburg and Sine Larsen, Centre for Crystallographic Studies, Chemistry Laboratory IV, University of Copenhagen, Universitetsparken 5, 2100 Copenhagen Ø, Denmark

Structural and physico-chemical studies of racemic and optically active monofluoro-substituted mandelic acids have revealed a number of interesting intermolecular interactions in addition to the expected O-H…O hydrogen bonds, e.g. C-F contacts and C-H…O hydrogen bonds[1,2]. A topological analysis of the theoretical (periodic Hartree-Fock) charge density for optically active *p*-fluoromandelic acid showed (3,-1) critical points between carbon atoms from adjacent phenyl groups. In order to analyse the intermolecular interactions further we have collected a data set to high resolution ($\sin\theta_{max}/\lambda = 1.12$ Å^{-1}) and of high quality (R_{int}=0.0172) for optically active *p*-fluoromandelic acid. The compound crystallises in space group C2 and we are aware that the subsequent analysis could be hampered both by the lack of phase restrictions in non-centrosymmetric space groups and the lack of accurate (neutron) parameters for the hydrogen atoms. Different approaches have been employed to investigate how this lack of information influences the experimental charge density. This includes a comparison of the results obtained using different multipole refinement programs, XD[4] and VALRAY[5], and a comparison with the theoretical charge density.

P06.13.008 A CHARGE DENSITY STUDY OF THE EFFECT OF IRRADIATION α-FORM OF π-NITRO-PHENOL. P. Kumaradhas, R. Srinivasa Gopalan, G. U. Kulkarni, Chemistry and Physics of Materials Unit, Jawaharlal Nehru Centre for Advanced Scientific Research, Jakkur, Bangalore – 560 064, India

A careful investigation of the structure and charge density of the α polymorph of *p*-nitrophenol has been carried out following prolonged irradiation by visible light. Though the change in color from yellow to red is remarkable, the molecular geometry and the intermolecular hydrogen contacts exhibit only minor changes. However, a charge density analysis in comparison with the pristine α and the β polymorphs has brought out significant differences in the charge distribution in the intra- and intermolecular bonding regions. The deformation density map of the α form reveals many differences in the bonding regions of the molecule before and after irradiation. Charge migration from the nitro and the hydroxyl groups to the phenyl ring of the molecule occurs on irradiation, resembling more like the charge distribution in the light stable β form. The molecular dipole moment in the irradiated crystal has been compared to that before irradiation. Relief maps of the negative Laplacian in the hydrogen bond region show less polarization of the oxygen lone-pairs compared to before irradiation.

P06.13.009 ELECTROSTATIC PROPERTIES OF NITROANILINES. J. Ellena, Instituto de Física de Saõ Carlos, USP, C.P. 369, 13560, Saõ Carlos, SP, Brasil, A.E. Goeta and J.A.K. Howard, Chemistry Department, Durham University, Durham DH1 3LE, UK, and G. Punte, LANADI y PROFIMO, Depto de Física, UNLP, CC 67, (1900) La Plata, Argentina.

The needs of the telecommunications industry have stimulated the research and develop of organic materials presenting non-linear optical responses. In this context, nitroaniline derivatives have been widely studied in the literature. However, some of the results coming from the currently available new techniques have renewed the interest in them, showing the need for a revision of both the existing knowledge on these compounds and the models which have been used to analyze them. In order to contribute to the understanding of these systems, the electron charge distribution of 2-methyl-5-nitroaniline was determined from high-resolution X-ray diffraction and neutron diffraction data, and compared with the one obtained from *ab-initio* calculations. The present work would indicate that the N-H...O interactions that generate the nitroaniline polar chains are two-centres interactions. The redistribution of the molecular

charge density, induced by molecular aggregation, explains the observed Car-H...O interactions, that help to stabilize 2-methyl-4-nitroaniline and other related compounds, with chains build from similar N-H...O synthons and assembled head-to-head. It has also been established that the in-crystal molecular electric dipolar moment is higher than that of the free molecule, the latter coincident with the one in solution. This finding along with the topological analysis of the electron charge density and the comparison of the experimental and theoretical determined electrostatic potentials seem to indicate the existence of cooperative effects.

P06.13.010 ELECTROSTATIC ENERGIES AND X-RAY DATA REFINEMENT. N.J. O'Toole and V.A. Streltsov, Crystallography Centre, The University of Western Australia, Nedlands, WA 6907, Australia.

The electrostatic self-electronic energy (E_{es}) has been computed from a variety of accurate X-ray data sets. It is demonstrated that by consideration of this property during data refinement, the obscuration of important features in experimental $\Delta\rho$ distributions due to biasing of parameters such as the structure factor scale can be avoided.

E_{es} is a relatively simple functional of the ground-state charge density in a crystal. The conventional representation of crystalline electron density ρ as the sum of the "pro-crystal" density ρ_{pro} and the deformation density $\Delta\rho$ leads to the expression of E_{es} as $E_{pro} + \Delta E$, these terms being the energy of the pro-crystal and deformation density respectively. It has been shown that E_{pro} is a rather good first approximation to the experimental cohesive energy for a wide range of materials [1]. The remaining (presumably small by comparison to E_{pro}) contributions to the cohesive energy are from charge transfer and polarization effects (i.e. ΔE) and the exchange/correlation energy.

Calculations of ΔE using the highly accurate experimental and theoretical data sets for the Group IV elements illustrate an extreme sensitivity of ΔE to the structure factor scale. Minute variations in the scale yield ΔE values with an unphysical magnitude. This sensitivity has been exploited during the refinement of synchrotron X-ray data sets for the rutile-type structures CoF_2 and ZnF_2, collected at the "Photon Factory" (Tsukuba, Japan); the scale and extinction parameters were constrained to produce $\Delta\rho$ distributions with physically reasonable energies. Much useful qualitative information in these $\Delta\rho$ maps is obscured without inclusion of this technique.

P06.13.011 CONTRIBUTION TO THE CHARGE DENSITY STUDIES OF Cu^{II}-COMPLEXES. J. Kozisek, Department of Inorganic Chemistry, Slovak University of Technology, SK-81237 Bratislava, Slovakia, H. Fuess, Material Science, Darmstadt University of Technology, D-64287 Darmstadt, Germany and N.K. Hansen, Laboratoire de Cristallographie et Modélisation des Matériaux Minéraux et Biologiques, Université Henri Poincaré, BP 239, 54506 Nancy CEDEX, France.

More than 8800 crystal structures of co-ordination compounds with Cu^{II} central atom in Cambridge Structural Database is an evidence of big variety of compounds with this element. Our recent study revealed the changing of reactivity of the ligand due to his co-ordination to the central atom. A nucleophilic addition of small molecules (methanol, water) to non-linear pseudohalides (like dicyanamide and nitrosodicyanomethanide), in the co-ordination sphere of *3d*-elements [mainly Cu(II), Ni(II) and Co(II)] leads to the formation of new anionic ligand [1,2]. Reactions in the co-ordination sphere of central atoms are of big importance not only for co-ordination chemistry. The systematic study of *d*-electron distribution in different co-ordination polyhedra of Cu^{II} could throw a new light on understanding the essentially properties of co-ordination bond. In order to examine the redistribution of valence electron density in different co-ordination environment charge density studies on some chosen compounds was done.

Experimental diffraction data were obtained with a Stoe Stadi 4 dif-fractometer at 120(1)K using the Oxford cryosystems low temperature attachment. A typical strategy for the data collection was to measure low angle reflections ($0 < \theta < 30°$), and the high angle reflections ($30 < \theta < 45°$). For the absorption correction the crystal habitus was measured and a Gaussian quadrature method employed.

The results of the multipole refinement will be discussed.

P06.13.012 CHARGE DENSITY STUDY OF AN ANTITHROMBOTIC DRUG - NEW ASPECTS IN DRUG DESIGN. R. Flaig and P. Luger, Institut für Kristallographie, Freie Universität Berlin, Takustr. 6, 14195 Berlin, Germany, and R. Soyka, Boehringer Ingelheim Pharma KG, Biberach, Germany, and T. Koritsánszky, Department of Chemistry, University of the Witwatersrand, Private Bag 3, WITS 2050, Johannesburg, South Africa

It has recently been shown [1] that the short data acquisition time using CCD area detection makes it possible to collect high quality X-ray diffraction data suitable for charge density determination. Such advances allow the method [2] to be applied for large systems of biological and pharmacological importance and open new perspectives for molecular modelling, recognition and drug design. We present a diffraction experiment, leading to a high resolution data set ($\sin\theta/\lambda_{max} = 1.24$ Å^{-1}, MoKα) of approximately 220000 reflections collected at 100 K with a CCD area detector, and the corresponding electron density of an antithrombotic drug containing more than 50 atoms. The multipole refinement and the topological analysis [3] of the static electron density was carried out with the program package XD [4]. All atom-atom interactions were characterized based on the topology of the density. In addition, different electronic properties of the crystalline state (dipole moment and electrostatic potential) were derived from the data and compared with those obtained from the wave function at the Hartree-Fock level of theory for the isolated molecule.

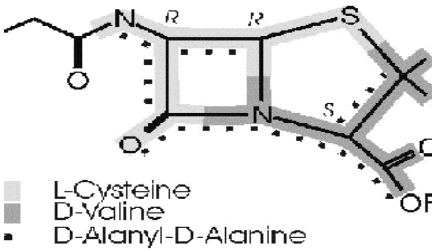
P06.13.013 CHARGE DENSITY STUDY ON THREE PENICILLIN DERIVATIVES. A. Wagner, P. Bombicz, R. Flaig, P. Luger, Institut für Kristallographie, Freie Universität Berlin, Takustr. 6, 14195 Berlin, Germany, and T. Koritsänszky, Department of Chemistry, University of the Witwatersrand, Private Bag 3, WITS 2050, Johannesburg, South Africa

Due to recent theoretical and experimental developments in charge density determination it is now possible to examine

large molecules of pharmaceutical interest. With the combination of the highly intensive synchrotron radiation and a CCD area detector one can collect high resolution data sets in a few days [1]. Penicillins, although being in therapeutical use for several decades, still provide the most widely used antibacterial drugs. An enormous amount of chemical derivatives have been synthesized and tested. The penicillin ring skeleton is formed by L-cysteine and D-valine and therefore it contains the D-alanyl-D-alanine moiety.



Based on the work on several amino acids we started to investigate the charge density of penamecillin, its corresponding biological inactive 1-β-sulfoxide and free phenoxymethylpenicillin. Intensity data of 73961, 80595 and 54463 reflections were collected at the beamlines F1 and D3 (HASYLAB/DESY, λ~0.5Å) with a Bruker SMART CCD area detector at 100 K up to a resolution of $\sin\theta/\lambda$ = 1.08, 1.26 and 1.24. A multipole refinement (program package XD) and a subsequent topological analysis was performed. In addition theoretical charge densities based on HF/6-311++G(d,p) wave functions were generated. A comparison of molecular topological properties of the three penicillin derivatives is presented.

P06.13.014 FROM AMINO ACIDS TO DIPEPTIDES - AN EXPERIMENTAL CHARGE DENSITY STUDY. B. Dittrich, P. Luger, R. Flaig, Institut für Kristallographie, Freie Universität Berlin, Takustr. 6, 14195 Berlin, Germany, and T. Koritsánszky, Department of Chemistry, University of the Witwatersrand, Private Bag 3, WITS 2050, Johannesburg, South Africa.

The topological analysis of the total electron density leads to the real-space definition of density units associated with atoms or functional groups [1]. The tranferability of different electronic properties of these subsystems is essential to the theoretical building of macromolecules from monomers [2]. Such applications might be limited to the extent to which the topology of the density is affected by the molecular conformation and intermolecular interactions. The study of experimental densities being characteristic to the crystalline rather than to an isolated state are well suited to elucidate these effects. Here we examine the transferability of simple topological properties of the electron densities extracted from X-ray diffraction data and compare the results obtained for a dipeptide with those of the building amino acids. The analyses are performed by the computer package XD [3] and based on synchrotron CCD data (HASYLAB/DESY) for the former and conventional (AgKα) data collected at around 20K for the latter structures.

We thank the BMBF (project 05 SM8 KEA 0) and the Fonds der Chemischen Industrie for financial support

P06.13.015 THE CHARGE DENSITY AND THE DIPOLE MOMENT OF PHOSPHANGULENE, A MOLECULAR PYROELECTRIC MATERIAL. Georg K. H. Madsen, Finn K. Larsen, Department of chemistry, University of Aarhus, DK-8000 Århus C, Denmark. Frederik C. Krebs, Macromolecular Chemistry Group, Department of Solid State Physics, Risø national laboratory, DK-4000 Roskilde, Denmark.

The charge density of the molecular pyroelectric material phosphangulene has been studied by multipolar modelling of very low-temperature (10 K) AgKα X-ray diffraction data, and the solid state dipole moment is evaluated. Due to the stacking arrangement of the molecules in the polar space group and consequent electric field over the crystal, the dipole moment in the solid state is enhanced compared to the value measured in chloroform and that calculated by *ab initio* methods for a gas phase molecule.

A polar space group is a prerequisite for a material to exhibit pyroelectric properties. Phosphangulene belongs to the space-group R3m.[1] Two main factors contribute uncertainty to the derivation of a reliable solid state dipole moment, namely the non-centrosymmetry of the spacegroup and the precision and accuracy of the hydrogen atom parameters. The influence of the non-centrosymmetry on the accuracy of the extracted electron density[2,3] is evaluated by modelling a set of theoretically calculated structure factors. The second main factor influencing the accuracy of the evaluated dipole moment is the modelling of the hydrogen pseudo-atoms. The high-symmetry space-group and the relatively small trigonal unit cell (a=b=16.654(1) Å, c= 4.166(1) Å) allows the determination of the hydrogen positions by neutron powder diffraction. An improved value for the pyroelectric coefficient of phosphagulene is estimated on the basis of the derived solid state dipole moment.

P06.13.016 THE MOLECULAR POLARIZABILITY OF NON LINEAR OPTICAL COMPOUND FROM X-RAY DIFFRACTION STUDY. F. Hamzaoui, N. Bettahar, A. Addou [1], F. Baert [2], [1] I.C.I. Université de Mostaganem. BP. 188 Mostaganem 27000 Algeria, [2] L.D.S.M.M. Université de Lille1. 59655 Villeneuve d'Ascq France

The ambition underlying this work, in addition to the electronic density determination is to revisit the earlier Robinson model which proposed to derived the non linear optical properties of a molecule from its ground state charge distribution.[1] The Robinson model has been applied to the 3-Methyl 4-Nitropyridine N-Oxide (POM) a prototypical nonlinear organic crystal, whereby relations between polarizabilities and multipolar moments of the electronic charge distribution have been evidenced. The experimental electronic density analysis has been carried out by use of the aspherical model of Hansen and Coppens. The electrostatic moments were then estimated by direct integration methods using both discret and fuzzy boundary space partitioning. Atomic net charges and dipolar moments derived therefrom clearly evidence the donor-acceptor character of substituents attached to the pyridine transmitter. The dipolar molecular

moment obtained by several methods have similar values, of the order of 1 Debye, in agreement with the small to vanishing dipole feature purposely engineered in POM.[2] The obtained results mimic very closely those published recently by Fkyerat et al. on the N-(4-nitrophenyl)-(L) Prolinol (NPP) another very efficient nonlinear optical compound.[3] The average value of linear polarizability is in agreement with the corresponding one inferred from the Finite Field Method. However, It seems difficult to infer from the Unsöld approximation a faithful description of the molecular optical properties, whereas an estimation of the first order hyperpolarizability components seems out of reach.

P06.13.017 DIPOLE MOMENT DETERMINED BY QUANTUM THEORY OF ATOMS IN MOLECULES. C. Flensburg, and S. Larsen, Centre for Crystallographic Studies, University of Copenhagen, Denmark.

The dipole moment is one of the properties, that can be derived from a charge density, which has been subject to considerable attention. The literature contains several examples of the determination of the dipole moment of molecular entities in crystals based on diffraction data that rely on different schemes of space partitioning[1].

The dipole moment of the water molecules has been determined employing the *Quantum Theory of Atoms in Molecules*[2] on the experimental charge distribution of methylammonium hydrogen succinate[3] and oxalic acid dihydrate[4]. The determination of the zero-flux surfaces was performed with the program VALRAY98 [5]. The dipole moments derived from the experimental data compare well with the equivalent quantities determined from the theoretical charge distributions obtained by the *ab initio* method as implemented in the programs CRYSTAL95 [6] and TOPOND97 [7]. The differences between the dipole moment of the water molecule in the two structures can be related to differences in their crystalline environments.

The dipole moments determined by application of QTAM are compared with the results derived from the conventional methods of obtaining the dipole moment from experimental charge distributions.

P06.13.018 EXPERIMENTAL CHARGE DENSITY STUDY OF THE MN-MN BOND IN $Mn_2(CO)_{10}$. Paul R. Mallinson, Louis J. Farrugia, and Dmitrii S. Yufit, Chemistry Department, University of Glasgow, Glasgow G12 8QQ, UK.

Complexes with direct bonds between transition metals have been of interest for some time, especially in the context of the Cluster-Surface analogy. A number of charge density studies on relatively simple examples of such compounds have been carried out in the past, in order to understand the nature of the metal-metal bond. These have almost exclusively been X-X or X-N studies on the deformation density.

One interesting example is $Mn_2(CO)_{10}$ which is a fundamental example of a compound containing an unsupported metal-metal bond. The suggestion of Bader [1] which identifies a bond path as a universal indicator of a bonding interaction has led us to re-examine the charge density in $Mn_2(CO)_{10}$ using this methodology. During the course of these investigations, another such study was also reported by Italian workers [2]. The package XD [3] was used in a multipole refinement with X-ray diffraction data, to obtain bond path and critical point (CP) analyses. The distribution of atomic charges is consistent with some occupancy of the valence π^* orbitals of the CO ligands *via* back bonding from the manganese. (3,-1) CPs are situated on cross-interaction lines linking the Mn atoms with two equatorial carbon atoms of a C_2-related $Mn(CO)_5$ unit. In the region earlier supposed to be the site of metal-metal bonding, where there is only a small density accumulation, the topological feature is found to be a ring CP, rather than a bond CP.

P06.13.019 MOMENTUM DENSITY OF K_XC_{60}. Ch. Bellin, M. Marangolo, G. Loupias, LMCP, Université Paris VI, case 115, 4 place Jussieu, 75252 Paris cedex 05, France, J. Moscovici, LPMD, Université Paris XII, UFR Sciences, 61 Av. du Général de Gaulle, 94010 Créteil, France, S. Erwin, Complex Systems Theory Branch, Naval Research Laboratory, Washington DC 20375, USA, S. Rabii, Dept. of Electrical Engineering, University of Pennsylvania, Philadelphia, PA 19104, USA

Compton scattering measurements have been demonstrated to provide an accurate check of conduction and valence electron densities of solids, in the electronic ground-state. Since the scattering is incoherent, this technique, which is a bulk probe, is insensitive to crystal defects.

Compton profiles, i.e. energy-loss spectra of scattered photons were measured on powder samples, using 16keV monochromatic beam provided by the french synchrotron facility. All the K_XC_{60} samples (x=3,4, and 6) were intercalated and kept under controlled atmosphere all the time. For comparison, C_{60} powder was measured in same experimental conditions. Theoretical Compton profiles were calculated from the *ab initio* SCF ground-state wavefunctions. These calculations were carried out within the local-density-approximation (LDA) by the LCAO technique and using all electron potentials. The directional profiles were then averaged for comparison with the measurement on powder samples.

In order to describe the electronic structures, differences between K_XC_{60} and C_{60} measured Compton profiles are compared with theoretical profile differences. Since Compton scattering is particularly sensitive to the hybridization between carbon and alkali orbitals as it was demonstrated in the case of graphite intercalation compounds, the distorsion of C_{60} molecule is discussed as a function of x. In addition, "charge transfer" between the intercalate and the C_{60} molecules as well as magnitude of e^--e^- correlations (essential to understand the superconductivity) are studied in this set of materials.

P06.13.020 THE EXPERIMENTAL CHARGE DENSITY DISTRIBUTION IN 4-STYRYL-7-FLUOROCOUMARIN: FIRST SHORT F...F INTERACTION. Tayur N. Guru Row[a], Paul R. Mallinson[b], Marahanakuli D. Prasanna[a], and Simon J. Teat[c], [a]Indian Institute of Science, Bangalore 560012, India. [b]Chemistry Department, University of Glasgow, Glasgow G12 8QQ, UK. [c]CCLRC Daresbury Laboratory, Daresbury, Warrington WA4 4AD, UK.

Fluoro substituted styryl coumarins have been studied recently to understand the principles of photodimerization in engineering such molecules in the crystal lattice [1]. The title compound is an unique exception in not generating the crystal packing favourable for the photo reaction. The presence of a short F...F contact across the centre of symmetry appears to be dominant in the crystal packing. Recent charge density studies [2] have clearly brought out the features of weak interactions and the present study aims at mapping the electron density distributions in a short F...F contact for the first time.

The data were collected at the CCLRC Daresbury CCD facility at 100K using radiation of wavelength 0.4855 Å. Multipole refinement using the XD [3] package preceded an analysis of critical point (CP) properties. The CP and bond paths clearly establish the features and properties of the F...F intermolecular interaction.

P06.13.021 MAGNETIC STRUCTURE DETERMINATIONS AND PHASE TRANSITIONS IN $(Mn_{1-x}Fe_x)Sn_2$. B. Lebech, Condensed Matter Physics and Chemistry Department, Risø National Laboratory, Denmark, and A. Menshikov and A. Vokhmyanin, Institute of Metal Physics RAS, Ural Division, Ekaterinburg, Russia, and H. Shiraishi Shibaura Institute of Technology, Oomiya, Soitama 330, Japan

With the aim to determine the magnetic phase diagram of the $(Mn_{1-x}Fe_x)Sn_2$ system we have collected neutron powder diffraction data for x = 0, 0.1, 0.2, 0.4, 0.6, 0.7, 0.85 and 0.9. The diffraction diagrams have been measured at various temperatures in the temperature range from 5 to 300 K and they were analysed by means of profile structure refinement in order to map out the magnetic phase diagram. The intermetallic compounds $MnSn_2$ and $FeSn_2$ crystallise in the *bct* C16 crystal structure. $MnSn_2$ orders magnetically below T_N = 325 K to a collinear antiferromagnet with alternating spins in the [1 1 0] layers (+ – + –), *i.e.* to a spin structure with wave vector $\boldsymbol{k}$ = (½ ½ 0). At T_2 ~ 74 K, this spin structure changes to a double layered structure (+ + – –). Below T_N =380 K, $FeSn_2$ orders to a collinear magnetic structure with wave vector $\boldsymbol{k}$ = (1 0 0). At T_2 ~ 93 K, this structure becomes non-collinear.

A major part of our efforts have been concentrated on understanding the concentration dependence of the antiferromagnetic phase transition close to x_c ~ 0.8 in the $(Mn_{1-x}Fe_x)Sn_2$ system. In this concentration region, the antiferromagnetic order with wave vector $\boldsymbol{k}_1$ = (½ ½ 0) changes to another magnetic structure with wave vector $\boldsymbol{k}_2$ = (1 0 0). The neutron diffraction data show that non-collinear magnetic structures exist in the transition region. These may be described by two co-existing orthogonal wave vectors $\boldsymbol{k}_1$ = (½ ½ 0) and $\boldsymbol{k}_2$ = (1 0 0). However, so far it has been difficult to explain the change of the paramagnetic Curie temperature from positive to negative with concentration and we expect that the present detailed neutron diffraction study of the $(Mn_{1-x}Fe_x)Sn_2$ alloy system can help us to overcome this problem.

P06.13.022 KOHN-SHAM ONE MATRICES FROM X-RAY DIFFRACTION DATA. Garry T. Smith and Vedene H. Smith Jr., Department of Chemistry, Queen's University, Kingston, Ontario, Canada, K7L 3N6.

Least-squares analysis of experimental structure factor data for extraction of the one-particle electron density requires a suitable model to be used in the fit. The multipole models currently in use provide a good fit to the data and chemically informative electron densities and related properties. However the electron density so obtained does not meet the fundamental requirements of quantum chemistry, *i.e* the N-representability criteria. For example there is no requirement for a strictly positive density built into the model.

An alternative model of the charge density is as an expansion of basis function products leading to a one-particle density matrix which reproduces the experimental density. Additionally, this matrix may be tested for N-representability by examination of its eigenvalues. Unfortunately the mapping between density and density matrix is, in the general case, non-unique. However by minimising the kinetic energy within the constrained search formulation of density functional theory, one obtains the wavefunction of the non-interacting system. This is a single Slater Determinant, composed of the Kohn-Sham orbitals which are the eigenvalues of the fitted density matrix up to a unitary transformation.

Several fitted Kohn-Sham one matrices for the experimental structure factors from formamide in the Gaussian basis sets STO-6G, 6-31G* and 6-311G** are analysed for both local and non-local properties, especially the non-interacting kinetic energy $T_s[\rho]$ and the "exact" exchange energy.

P06.13.023 CHARACTERIZATION OF A Li···H-C AGOSTIC INTERACTION BY A TOPOLOGICAL CHARGE DENSITY ANALYSIS. M. Grosche, W. Scherer, M. Gardener, W. A. Herrmann, Anorganisch-chemisches Institut, Technische Universität München, Lichtenbergstr. 4, D-85747 Garching, Germany

Alkyllithium complexes are of fundamental importance in organic synthesis and as anion transfer reagents in organometallic synthesis. Their crystal structures display a remarkable range of bonding modes. Complexes featuring a *lithium coordination number of only 2* - as in the investigated compound $[\{2\text{-}(Me_3Si)_2ClicC_5H_4N\}_2]$ **1** - have been observed in a rare number of cases. Little is known about the details of interactions which compensate for the electron deficiencies of the metal centres in their reduced coordination state, and include, (i) close Li···Li contacts and (ii), close *"agostic" type Li···H-C interactions.*

Agostic interactions as displayed by **1** are also of particular interest in organometallic chemistry in view of their potential relevance to important processes like C-H activation in catalytic reactions. Reliable ways of pinning down these interactions are still at a premium, notwithstanding the numerous examples reported on the basis of structural or spectroscopic measurements or of theoretical studies [1].

The nature of Li···H-C agostic interactions has been investigated by topological analysis of experimental charge densities in **1**. Strong agostic Li···H-C interaction are signalled by short Li···H distances [2] (of around 2.20 Å which are ca. 0.7 Å less than the sum of the Van der Waals radii of the lithium and hydrogen atoms).

Preliminary charge density studies based on high resolution X-ray data ($\sin\theta/\lambda_{max}$ = 1.17 @ 100K) lead to reasonable topological parameters for all bond critical points.

P09.13.001 THE ENDOHEDRAL STRUCTURES OF SCANDIUM METALLO-FULLERENES. E. Nishibori, M. Sakata, Department of Applied Physics, Nagoya University, Nagoya, Japan and M. Takata, Department of Material Science, Shimane University, Matsue, Japan and H. Shinohara, Department of Chemistry, Nagoya University, Nagoya, Japan.

The endohedral structures of scandium fullerenes, $Sc@C_{82}$ and $Sc_2@C_{84}$, are determined by the maximum entropy method (MEM) using synchrotron radiation powder data. The obtained MEM charge densities show a clear distinction of the endohedral natures of the mono- and di-metallofullerene.

From the MEM charge density of $Sc@C_{82}$, the cage structure of this molecule is determined to have C_{2V} symmetry. Inside the carbon cage, the Sc atom is located at an off-center position adjacent to a carbon six-membered ring. The nearest Sc-C distance determined from the MEM charge density is 2.53(8)Å. The charge transfer from Sc to fullerene is estimated as 2.2e.The Sc charge density has a saucer-like feature along the six-membered ring of the carbon cage.

The MEM charge density of $Sc_2@C_{84}$ clearly shows the D_{2d} symmetry cage structure. Inside the carbon cage, the Sc atoms are located in nearly symmetric positions with respect to the center of the cage. The encapsulated Sc-Sc distance and the nearest Sc-C distance are 3.9(1) Å and 2.4(1) Å. respectively. The positive charge of the Sc atom from the MEM charge density is determined as 2.2e. The charge transfer from Sc ions to fullerene is estimated to be 4.4e. The Sc charge density has tear drop feature as if the two Sc atoms are in a stretching vibration within the C_{84} cage.

The MEM charge density of $Sc@C_{82}$ molecule shows a strong contrast with that of $Sc_2@C_{84}$. The five and six-membered ring networks of $Sc_2@C_{84}$ can be seen more clearly than that of $Sc@C_{82}$.

P09.13.002 ELECTRON DENSITY DISTRIBUTION IN FAYALITE DETERMINED WITH SYNCHROTRON DATA. F.Marumo, Y.Tabira and M.Okui, Deptartment of Geosystem Sciences, Nihon University, Sakurajosui 3-25-40, Tokyo 156-8550, Japan, and N.Ishizawa, Materials and Structures Laboratory, Tokyo Institute of Technology, Nagatsuta 4259, Yokohama 226-8503, Japan, and O.Tamada,Graduate School of Human and Environmental Studies, Kyoto University, Kyoto 606-8316, Japan, and H.Takei, Faculty of Science, Osaka University, Toyonaka 560-0043, Japan.

Electron density distribution in a fayalite crystal (Fe_2SiO_4) has been re-examined by collecting diffraction data with 0.750Å synchrotron radiations. The specimen was shaped into a sphere with the diameter of 0.040 mm. The minimum and maximum transmission factors are 0.7235 and 0.7328 for the 200 and 74,11 reflections. The structure refinement with the free ion model converged to give the R and Rw values of 0.020 and 0.022 for 2047 independent reflections. In the difference Fourier map synthesized after the refinement, positive residual densities with 1.5 e $Å^{-3}$ heights are observed at positions about 0.5 Å apart from Fe(2) along the a-axis on either side of the atom. In addition, positive residual densities of about 0.5 e $Å^{-3}$ and 0.3 e $Å^{-3}$ heights are observed around Fe(2) at distances of 0.5Å along b. The map is much flatter around Fe(1) than around Fe(2). The highest peaks around Fe(1) have heights 0.5 e $Å^{-3}$, locating at 0.5 Å apart from Fe(1) approximately in the direction parallel to a. An ab-initio calculation of the electronic state was carried out by the DV-Xa method. Differences between the theoretical and promolecular electron densities were evaluated and compared with the experimental results. Features of the theoretical residual densities are qualitatively in an agreement with those of the experimental ones around Fe(2), whereas no good agreement was obtained around Fe(1). The estimated net charge of Fe(2) is larger than that of Fe(1) in conformity with the crystal chemical evidence

P09.13.003 BOND CHARACTERS OF MnS_2 BY SYNCHROTRON X-RAY DIFFRACTION AND MOLECULAR ORBITAL CALCULATIONS. S. Kuze, N. Ishizawa and M. Ueki, Materials and Structures Laboratory, Tokyo Institute of Technology, 4259, Nagatuta, Midori-ku, Yokohama 226-8503, Japan

MnS_2 is a paramagnetic semiconductor with a pyrite-type structure. Mn has a $3d^5$ electron configuration with the *d* electrons in the high-spin states. The electron density distribution of MnS_2 was investigated by single crystal X-ray diffraction with a horizontal-type four-circle diffractometer at KEK BL14A using synchrotron radiation with the wavelength of 0.75Å [1]. The least-squares refinement, employing atomic scattering factors of neutral atoms, yielded a final R/Rw value of 0.0119/0.0122 for 539 independent reflections in the range $2\theta<138°$. In the difference Fourier maps, an accumulation of electron density was found slightly off from the line connecting Mn and the first neighbour S.

To clarify the contribution of atomic orbitals to the bonding between Mn and S, DV-Xα molecular orbital calculations were carried out using the SCAT program package [2]. The result suggested that the 3*d* atomic orbitals of the Mn atoms and the 3*p* orbitals of the first and second neighbour S atoms were mixed together to form molecular orbitals which are responsible for the observed charge density topography between the Mn atom and S_2^{2-} molecule.

P09.13.004 MAXIMUM ENTROPY ELECTRON DENSITY ANALYSIS OF CHEMICAL INTERACTIONS IN ANHYDROUS SODALITES. Bo Brummerstedt Iversen, Department of Chemistry, University of Aarhus, DK-8000 Århus C, DenmarK, Susan Latturner, Galen Stucky, Department of Chemistry, University of California, Santa Barbara, CA 93106, USA

We have carried out combined Rietveld and maximum entropy method (MEM) analysis on synchrotron X-ray powder diffraction data of a series of anhydrous sodalites, $M_6(AlSiO_4)_6$, M = Na, Ag, Tl. Analysis of the MEM electron densities reveals the nature of the interactions in the structures. The sodium atoms are bonded to the framework with predominantly electrostatic closed shell interactions, whereas the heavy metal ions form partly covalent bonds to the framework oxygens. At the same time the heavy metal atoms are close to being neutral, while the sodiums, as expected, are positively charged. The differences in the atomic charges and in the chemical interaction between the guest atoms and the framework can explain the varying dynamical behaviour of the guest atoms. While the alkali system exhibit a phase transition due to dipole-dipole interactions creating an ordering of the metal atoms, the heavy metal systems remain pseudocubic with a locked in static disorder. The guest-host interactions have pronounced effects on the framework atoms with Al, especially, showing reduced density. The removal of electron density from the framework bonds upon formation of covalent guest-host bonds

is the cause of the abnormal chemical shifts and quadrupole coupling constants found in NMR for the heavy metal compounds.

The thallium compound is of particular interest due to the presence of a completely regular array of quantum confined Tl clusters. The electron density does not show evidence of stereoactive lone pairs, which are often postulated to be present in low valent Tl-compounds. It is furthermore found that the Tl cluster has weak covalent bonding interactions between every pair of Tl atoms in the cluster. This is somewhat at variance with *ab initio* calculations on simple RTl-TlR model dimers, and may be a result of the ability of porous frameworks to alter the electronic structure, and thereby the chemical reactivity, of suspended guest species. The fact that experimental electron densities can be derived from powder diffraction data gives great promise for increasing the understanding of the chemical and physical properties of a wide range of technologically important materials.

P09.13.005 ELECTRON AND NUCLEAR DENSITIES OF HYDROGEN IN KDP AND ADP BY MAXIMUM ENTROPY METHOD. Shigefumi Yamamura and Yoko Sugawara, Department of Physics, School of Science, Kitasato University, Sagamihara 228-8555, Japan and Masaki Takata, Department of Material Science, Interdisciplinary Faculty of Science and Engineering, Shimane University, Matsue 690-8504, Japan and Makoto Sakata, Department of Applied Physics, Graduate School of Engineering, Nagoya University, Nagoya 464-8603, Japan.

In order to investigate the nature of the hydrogen bond, the electron and nuclear density distributions of KDP (KH_2PO_4) and ADP ($NH_4H_2PO_4$) were obtained by the maximum entropy method (MEM) using X-ray and neutron powder diffraction data. In this study, no single crystals and no deuterated samples were used, although single crystal analysis is believed to provide accurate structural information compared with powder one and deuterated specimens are often used for neutron diffraction experiments with hydrogen compounds to reduce the large incoherent scattering from protons.

KDP and ADP is hydrogen-bonded ferro- and antiferroelectrics, respectively. In both compounds, hydrogen atoms are considered to play an important role in phase transition and the phase transition temperature is increased by about 100 K when hydrogen atoms are substituted by deuterium atoms. In order to explain such a large isotope effect, it is necessary to understand the behavior of hydrogen as well as that of deuteron. In this study, it is demonstrated that the nature of the hydrogen bond in KDP and ADP can be described by MEM using only powder data. It is not an easy task to detect the precise electron and nuclear density distributions of hydrogen bond, because the scattering power of hydrogen for X-ray is markedly lower than that of other elements and the large incoherent scattering from protons cannot be avoided in neutron diffraction experiment.

The data sets used in the analyses were collected at the Photon Factory, Tsukuba for X-ray data and at Japan Atomic Energy Research Institute, Tokai for neutron ones. The powder data were analyzed by a sophisticated method which is the combination of Rietveld method and MEM.[1] From the MEM electron density maps in O-H-O hydrogen bond at room temperature, hydrogen shows no local maxima but contour lines link two O atoms. This feature is consistent with corresponding nuclear density maps in which proton shows double maxima in the two O atoms. Furthermore, it could be detected that the electron density distribution of N-H-O, another hydrogen bond in ADP, shows rather ionic nature, which is different from that of O-H-O.

[1] M. Takata *et al.*, Nature (London), **377** (1995) 46.

P09.13.006 MULTI-POLE ANALYSIS OF HEXA-METHYLENETETRAMINE IN REAL SPACE USING MEM ELECTRON DENSITIES. T.Ikeda and M.Sakata, Department of Applied Physics, Nagoya University, Nagoya, Japan and M.Takata, Department of Material Science, Shimane University, Matue, Japan

In conventional multi-pole analysis, the least squares calculations are executed in reciprocal space by using multi-pole structure factors, although a multi-pole electron density model is constructed in real space. Multi-pole structure factors are, of course, the Fourier transformation of multipole electron density model. This process may cause unnecessary complexities and severe co-relations between multi-pole parameters. By using the Maximum Entropy Method (MEM), it is now possible to derive an electron density distribution, which is consistent with the observed structure factors. This brings a new possibility to perform a multi-pole analysis in real space. In this study, we tried a real space multi-pole analysis that is to fit the multipole density model to the MEM in the case hexamethylenetetramine ($C_6H_{12}N_4$).

X-ray diffraction data is collected by powder method using Synchrotron Radiation at KEK PF BL-6A$_2$. Electron densities are obtained by the combined analysis of MEM and Rietveld method. Multipole refinement is executed in real space by using Stewart model. Multi-pole densities are agreed with MEM densities except core regions. From the obtained multipole deformation map, the strong C-N and the weak C-H covalent bond electrons are clearly shown. It should be noted that the real space multi-pole analysis does not suffer severe co-relation of parameters and that MEM charge densities helps to construct multi-pole model.

P09.13.007 CHARGE DENSITY DATA SETS FROM 1 AND 2 K CCD DETECTORS, MO AND AG RADIATION, N_2 AND He COOLING. A.A. Pinkerton, P. Burckel, Y.-S. Chen, K. Kirschbaum, A. Martin and D. Parrish, Department of Chemistry, University of Toledo, Toledo, OH 43606, USA.

A series of charge density studies have been carried out on a number of small organic molecules. All data were collected with SMART platform diffractometers. Some used a 1 k CCD detector, others a 2 k CCD detector. Some were measured using liquid nitrogen cooling (90 K), others were cooled with liquid helium (20 K). Some were measured using Mo-Kα radiation, others using Ag-Kα radiation.

The differences in the data collection protocols using the various experimental conditions will be presented. The quality of the data thus obtained will be statistically analyzed. Selected deformation maps will be presented for comparison purposes.

P09.13.008 EXPERIMENTAL ELECTRON DENSITY ON COBALT BISHYDROGENMALEATE TETRA-HYDRATE. N. G. Fernandes, M. D. D. Costa, Department of Chemistry, Federal University of Minas Gerais, CP 702, 31270-901, Belo Horizonte, Br

Metal hydrogenmaleate, M(C4H3O4)2(H2O), M = Mn, Fe, Co, Ni, Zn are known be isomorphic with ligand and water molecules forming a infinite network of H-bonds and a short intramolecular hydrogen bond. The present work reports a deformation refinement for cobalt compound.

X-ray data were collected on a SIEMENS four-circle diffractometer at 100K, using MoKα radiation up to $\sin\theta/\lambda$ = 1.20Å^{-1}. For a P space group, 9529 reflections were measured, 8089 unique reflections. In the final refinement, R(F^2) = 0.0487, wR = 0.0513.

The short hydrogen bond has a O---O distance of 2.415(1)Å, it is a quasi-linear intramolecular hydrogen bond. The

cobalt atom is surrounded by six oxygen atoms in a octahedral arrangement .

Static deformation density maps show Co atom in a pseudo 4/mmm site symmetry. In the water molecules two distinct maxima of ~0.50 e/Å^3 and lower broad peak of ~0.20 e/Å^3 in the lone pair region. For the short hydrogen bond, O---H---O, there are two maxima of 0.20 e/Å^3 between O---H bonds. Deformation maps also show that there are two types of C-C in the ligand.

P09.13.009 A CHARGE DENSITY STUDY ON THE INTER-METALLIC COMPOUNDS $MgZn_2$ AND $MgCu_2$ BY THE MAXIMUM ENTROPY METHOD. Yoshiki Kubota, Masaki Takata[1], Makoto Sakata[2], Takuya Ohba[3], Kouichi Kifune and Tsugio Tadaki, Department of Natural Science, Osaka Women's University, Sakai, Osaka 590-0035, Japan, [1]Department of Material Science, Shimane University, Matsue 690-8504, Japan, [2]Department of Applied Physics, Nagoya University, Nagoya 464-8603, Japan, [3]Department of Materials Science and Engineering, Teikyo University, Utsunomiya 320-8551, Japan.

The charge density distributions of the intermetallic compounds $MgZn_2$ and $MgCu_2$ were obtained by the maximum entropy method (MEM). In the MEM charge density map of $MgCu_2$, the overlapped electron densities were seen between the Cu atoms. It is probably due to the hybridization of atomic orbitals to form Cu-Cu covalent bond. There are practically no overlaps of electron densities between Mg atom and Cu atom. It was found that the Cu-Cu covalent bond is forming a tetrahedral kagome network. By the geometrical consideration, such a feature of bonding with six lobes can be interpreted as p^3d^3 hybridization. In addition to the Cu-Cu bond, the shift of bonding electron from the line connecting the Cu atoms toward the Mg atom was found. The valence of Mg atom was estimated to be about +2. This shows that there are an ionic interaction between the Mg atom and the hybridized orbitals.

As for the $MgZn_2$, the fundamental features of the charge density, which are the covalent bond between the Zn atoms, the shift of bonding, were essentially the same as $MgCu_2$. But the MEM map of $MgZn_2$ shows the less covalency within the kagome net plane. By the geometrical consideration, the bonding due to the p^3d^3 hybrid orbitals has a slight distortion by the hexagonal zigzag stacking sequence in $MgZn_2$, while the tetrahedra with sharing corners by the ABCABC stacking sequence in $MgCu_2$ does not distort p^3d^3 hybrid orbitals. It may be interpreted that the distortions of the p^3d^3 hybrid orbitals cause a decrease of bonding electrons of the kagome net plane in $MgZn_2$. The analysis for $MgNi_2$ is now in progress.

P09.13.010 SOME CHARACTERISTICS OF MEM CHARGE DENSITIES OBTAINED FROM UNIFORM PRIOR DENSITIES IN COLLINS' FORMALISM. M.Sakata, S. Morishita, T.Ikeda and E.Nishibori, Department of Applied Physics, Nagoya University, Nagoya 464-8601, Japan and M.Takata, Department of Material Science, Shimane University, Mtasue 690-8504, Japan

Collins (1982) developed a simple method to solve the Maximum Entropy (ME) equation. In his method, the prior density($\mathbf{r}$) at pixel $\mathbf{r}$ are replaced at each iteration by newly obtained density($\mathbf{r}$). It enables us to solve ME equation either from uniform or non-uniform prior density distribution. It is not well established what kind of prior densities to be used. The answer of such a question may not be just one but can be dependent what for ME used. The purpose of this study is to describe some characteristics of MEM charge density distribution to provide more materials to have the better answer for the question.

In a simple structure such as Be or CeO_2, so called artifact exists. When it appear, the artifact appears always at high symmetry position in a unit cell. In complicated structures, it does not appear. In the case of CeO_2, it disappears as the number of reflections is increased. Such an artifact is also found in difference Fourier map in CeO_2. In Be case, the appearance of the artifact is related what kind of error bar, □ is used. It is extremely difficult to conclude whether so called artifact in Be is purely artifact or just exaggerated.

It must be pointed out that it is not possible to derive 'true' or 'exact' electron density distribution from limited number of structure factors with ambiguities. This is why 'Entropy'; the measure of uncertainties, is introduced to analyze the experimental data which are limited and have some ambiguities. It must be advisable in many cases to use uniform prior knowing such characteristics of MEM charge densities rather than trying to find out the 'exact' densities by using non-uniform prior or some other method since the number of data experimentally available is always limited. It seems the ME method is based on the idea that the truth will never out.

1. D. M. Collins (1982) *Nature,* **298**, 49-51.

P09.13.011 AN ELECTRON DENSITY STUDY OF UREA-PHOSPHORIC ACID ADDUCT AT 100K. B. L. Rodrigues, N. G. Fernandes [1], R. Tellgren [2], [1] Department of Chemistry, Federal University of Minas Gerais, CP 702, 31270-901 - Belo Horizonte, Brazil, [2] Institute of Chemistry, University of Uppsala, Box 531, S-751 21 - Uppsala, Sweden.

The experimental electron density of the adduct compound $H_3PO_4.CO(NH_2)_2$ is reported. Phosphoric acid and urea are linked by a N-H---O bond and a very short O---H---O bond [d(O-O)=2.415(1)Å]. Data was interpreted using the Hirshfeld formalism. In the final model, 216 parameters were refined, R(F2)=0.0455 and wR(F2)=0.0529 for 7257 independent reflections.

Deformation density maps show maxima of 0.40e/Å^3 between phosphorus and hydroxyl oxygens, while two remaining P-O bonds have peak maxima of 0.50 e/Å^3. The electron density distribution in Urea region is similar to previous study on urea crystal [1].

The N-H---O bond has of electron density excess of 0.20e/Å^3 in the O---H line near oxygen. It is also observed in this line a depletion of 0.30e/Å^3 close to hydrogen atom. All other long hydrogen bonds in this compound have similar electron distribution. On the other hand, in the short O---H---O bond, there are two maxima peak heights of 0.40 and 0.60e/Å^3 approximately equidistant of O and H atoms.

P09.13.012 THE CHARGE DENSITY ANALYSIS OF 1,4,8,11-TETRATHIACYCLOTETRADECANE USING CCD DATA. Michael D. Carducci and John H. Enemark, Department of Chemistry, University of Arizona, Tucson, Arizona 85721

Recent advances in X-ray detector technology and data analysis software have greatly improved the results which can be obtained from charge density analysis of high quality, low temperature X-ray diffraction data sets. The remarkable increase in speed with which CCD area detectors allow data sets to be collected eliminate or greatly reduce error due to long term icing problems, X-ray beam stability(or availability) and crystal decay. Coverage of reciprocal space is more complete, has a higher redundancy, and is of higher accuracy, especially for weak reflections, when an area detector is utilized. At the same time, the software available for analyzing that data has matured from simply modeling the observed density to include determining molecular

properties and displaying results in color and multiple dimensions with the latest computer graphics techniques.

1,4,8,11-Tetrathiacyclotetradecane (TTCD) was previously examined in this laboratory [1] utilizing a serial diffractometer and the refinement program Molly [2]. Those results, which suffered from time dependent errors during two months of data collection, will be compared with a new data set determined with a CCD area detector diffractometer and refined with the XD package [3].

P09.13.013 DETERMINATION OF CHARGE TRANSFER AND IONICITY BY ELECTRON DIFFRACTION. J. Tafto [1], Lijun Wu, Yimei Zhu [2], [1] Department of Physics, University of Oslo, PO Box 1048, Blindern, N-0316 Oslo, Norway, [2] Materials Science Division, Department of Applied Science, Brookhaven National Laboratory, Upton, NY 11973, USA

In electron diffraction, the structure factors of reflections at low scattering angles are strongly influenced by the distribution of the valence electron distribution in the crystal. This makes electron diffraction an excellent technique to study charge transfer, in particular in crystals with large unit cells and thus reflections at very short reciprocal distances. We use convergent beam electron diffraction and focus the electron probe above a thin wedge-shaped area. By this procedure we acquire shadow images and thickness fringes of many reflections simultaneously [1].

We have used this approach to study the spatial distribution of divalent and trivalent iron in the crystal unit cell of magnetite, and to determine the electron hole distribution in high temperature superconductors. Our results are consistent with the hole distribution reported by other investigators based on electronic structure calculations, and the distribution which is inferred from bond valence calculations using accurate atomic positions from neutron diffraction data.

P09.13.014 ELECTRON DENSITY IN VANADIUM PENTOXYDE. Jean-Michel Savariault, Centre D'elaboration De Materiaux Et D'etudes Structurales - CNRS, 29 Rue Jeanne Marvig - BP 4347, 31055 Toulouse Cedex 4, France.

The vanadium oxide bronzes appear more and mode interesting as material electrode in lithium batteries and more recently as compounds with highly correlated electrons (spin chained, spin ladder, spin frustration...). The interpretation of such behaviours assumes that the starting material is well known. The divanadium pentoxide with a formula similar to the diniobium pentoxide exhibit a different structure. In order to understand these structural variation and such behaviours, the determination of the electron density in the divanadium pentoxide was undertaken by X ray diffraction. The measurement was performed at 135K with molybdenum radiation on a CAD4. The X-X technique was used and the cut-off was chosen at $0.8\ \text{Å}^{-1}$. The electron density around the vanadium atom appears as a dz^2 function oriented towards the O vanadyl, an accumulation of density along the axis and a deficiency in the plane of the layer perpendicular to the axis. The different sections show that each vanadium oxygen bonds exhibit different electron density distribution. The shape of each density around atoms will be discussed in term of bond type. A multipole treatment allows to extract information's about the charges on the atoms and the d orbital population around vanadium.

P09.13.015 CRYSTAL ORIENTATION DETERMINATION IN VCIP METHOD FOR ACCURATE MEASUREMENTS. K.Tanaka, E. Zhurova, [1] Y.Takenaka [2]. [1]Dept. Mat. Sci. & Eng., Nagoya Inst. Tech., Gokiso-cho, Showa-ku, Nagoya, 466-8555 [2}Hokkaido Univ. Education at Hakodate, Hachiman 1-2, Hakodate, 040, Hokkaido.

Vacuum camera (VC) is an evacuated cylinder with an imaging plate (IP) on the inside wall and allows for data collection by oscillation method. It enables to measure intensities without air-scattering. VC's are installed at our lab. and BL02B1 of SPring-8. It gave us Bragg peaks clearly at high angles. We call this method as VCIP (Vacuum Camera Imaging Plate) method. In spite of the advantage, refinement of intensity data of KNiF3 measured with VCIP gave almost the same results as those measured with four-circle diffractometer. The reason for it is quite clear. We could not get crystal orientation accurate enough to correct for systematic errors.

Since in our present VCIP method VC is removed from the diffractometer after each measurement and IP is also removed from VC for intensity readout, camera and detector parameters, and crystal orientations need be determined from the measured peak positions on IP. The correlations among them were analyzed and they were refined with the least-squares method. The camera parameters are;film radius, inclination of VC and displacement of the camera center from the crystal position. The film parameters are; incident beam position and IP rotation in the readout system. And each element of the orientation matrix of the crystal is refined. Finally observed and calculated peak positions of KNiF3 agreed within a pixel of 0.05x0.05mm2.

P09.13.018 STRUCTURAL PROPERTIES AND ELECTRON DENSITY DISTRIBUTION OF LUNI$_2$B$_2$C. U. Jaenicke-Roessler, P. Paufler and G. Zahn, Institut für Kristallographie und Festkörperphysik, Technische Universität Dresden, D-01062 Dresden, Germany.

Superconducting materials of the RT_2B_2C type (R=rare earth metal, T=transition metal) are of much interest concerning their physical and structural properties because of their relatively high superconducting transition temperatures T_C and because of the interesting interaction between superconductivity and magnetic ordering phenomena that they exhibit.

Single crystalline samples of $LuNi_2B_2C$ (a=3.46084 Å, c=10.63406 Å, space group (139) I4/mmm-edba, tI 12, T_C=16.6K [1]) were examined by monochromatized MoK_α radiation on a STOE Stadi4 four-circle-diffractometer at 15 different temperatures from T_1=360 K down to T_{15}=90 K. Precise lattice parameters were determined by a profile-fitting method utilising α_1-α_2-splitting of reflections at higher 2ϑ angles, refined over all reflections of the data collection with a certain I/σ_I-ratio. Data collection was carried out over a 2ϑ range from 3° to 120°, measuring a half sphere with Friedel pairs at -2ϑ, accounting to a total of 4242 reflections, thus reaching a resolution of 0.4103 Å. Agreement factors R of the least square refinements lie at about 2.4 % for all data.

Expansion coefficients α_a vary between $1.23\cdot10^{-5}$ K^{-1} and $0.422\cdot10^{-5}$ K^{-1}, α_c between $0.0918\cdot10^{-6}$ K^{-1} and $-3.38\cdot10^{-6}$ K^{-1} and bulk expansion β between $2.57\cdot10^{-5}$ K^{-1} and $1.06\cdot10^{-5}$ K^{-1}, at T_1 or T_{15}, respectively. They are smaller than for other RNi_2B_2C compounds we examined. α_c reverts sign as it does for other RNi_2B_2C compounds, too, but at a much lower temperature (at about 140 K).

The free structure parameter z_B (0.1392(4)) and the tetrahedral angle B-Ni-B' α (108.4(1)°) were examined with regard to temperature, but no significant dependence was found

taking the errors into consideration. Anisotropic temperature factors have been determined, confirming the general tendency for these compounds, that U_{ij} parallel to the c direction have the highest values.

Electron density distribution was refined for the first time starting from our measured intensities and contours were drawn [2]. These results were compared to theoretical considerations according to [3].

Our thanks are due to H. von Lips for supplying the specimens.

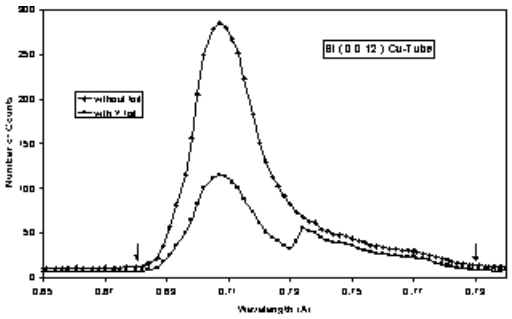
P09.13.019 X-RAY STRUCTURE BIAS DUE TO WAVELENGTH DISPERSION. A.T.H. Lenstra, B. Rousseau, Dep. Of Chemistry, University of Antwerp (UIA), Belgium.

While the phenomenon of dispersion is well known, its impact on the x-ray structure determination is seldom realized. We studied the various aspects with a standard CAD4-diffractometer in combination with an x-ray tube. This setup is representative for the usual situation in structure analysis.



The spectral distribution in a monochromated x-ray beam with λ = 0.71Å was analyzed via a Si (0 0 12) reflection. The beam spectrum – here in the absence of the characteristic Mo-K_α intensity – is shown in Figure 1. We observe a wavelength dispersion $\Delta\lambda/\lambda$ of 0.15 with λ_{min} = 0.68Å and λ_{max} = 0.79Å.

During data collection intensity measurements are made using a scan angle given by (a + b tg θ)° with b = $\Delta\lambda/\lambda$ 360/2π. With $\Delta\lambda/\lambda$ = 0.15 this scan angle becomes larger than the separation between individual Bragg spots along, say, C*. In our analysis of $NiSO_4.6H_2O$ (space group $P4_12_12$; a=6.782Å, c=18.274Å) we used a scan angle of (1.3 + 0.4 tg θ)°. This scan range is tailored to $\Delta\lambda/\lambda$ of 0.007 only. Therefore the practical scan underestimates the real reflection intensity due to spectral truncation. The truncation error increases with θ. Since B is the only model parameter linking I to θ, the spectral truncation leads to biased ADP-values with $B_{model} > B_{true}$.

The size of the truncation error is maximal in the absence of characteristic radiation. When the $\Delta\lambda$-window includes K_α emission lines the truncation error is minimal at the highest tube voltage.

Atom	Cu λ=0.71 Å	Mo-25kV λ=0.71 Å	Mo-50kV λ=0.71 Å	Synchrotron λ=0.64 Å
Ni	1.57(2)	1.285(5)	1.120(4)	1.020(8)
S	1.88(4)	1.466(7)	1.300(5)	1.215(12)
O1	2.90(10)	2.64(3)	2.46(2)	2.42(6)
O2	2.68(6)	2.36(2)	2.18(2)	2.11(5)
OW1	2.90(10)	2.47(3)	2.29(2)	2.22(5)
OW2	2.40(10)	1.89(2)	1.76(1)	1.64(4)
OW3	2.32(9)	1.80(2)	1.66(1)	1.57(4)

The impact of the truncation errors on the ADP's in $NiSO_4$ is shown in the table above, which includes a synchrotron model measured at Brookhaven with λ = 0.643Å. These ADP's are free from truncation-error because $\Delta\lambda/\lambda \approx 0.0002$. ΔB's between different measuring schemes appear to be temp. independent.

P06.14.002 THEORETICAL ANALYSIS OF SURFACE CONTRIBUTION TO TDS OF X-RAYS S.A.Grigoryan, I.A. Vartanyants, M.V.Kovalchuk. A.V. Shubnikov Institute of Crystallography, Leninsky pr. 59, 111395 Moscow, Russia.

Third generation synchrotron radiation facilities gives unique possibility for the study of inelastic X-ray scattering processes. One of such inelastic decay channels is Thermal Diffuse Scattering (TDS) of X-rays on thermal phonons. In the previous papers it was assumed, that the main contribution to the yield of the TDS is coming from inelastic scattering of X-rays on the volume acoustic modes of thermal vibrations. In this paper theoretical analysis is made for the contribution of the surface excitations to this process. The most effective way to take into account this processes is to express correlation function of atomic displacements through the corresponding Green functions of the elasticity theory. It will be shown that in the long wavelength limit of acoustic modes the contribution of the surface excitations to the TDS near the surface is becoming comparable and can even exceed the volume one. Peculiarities of the process while the dynamical scattering of X-rays, when in the crystal due to coherent superposition of the incident and diffracted wave exist the X-ray standing wave will be also discussed.

P06.14.003 BRAGG DIFFRACTION FOCUSING TECHNIQUES FOR NEUTRON SCATTERING INSTRUMENTATION. P. Mikula and M. Vrana, Nuclear Physics Institute, 250 68 Rez near Prague, Czech Republic, and M. Ono, Kyoto University Reactor Research Institute, Kumatori, Japan, and V. Wagner, Physikalisch Technische Bundesanstalt, 38116 Braunschweig, Germany.

By a simple implementation of the bent-perfect-crystal (BPC) elements on conventional scattering devices one can considerably benefit from real or/and momentum space focusing, especially for small slit-like samples. Working with open beams without Soller collimators [1-3] and with position sensitive detectors (PSD) such devices can be dramatically superior to the conventional ones equipped with flat mosaic crystals and multidetectors. A double crystal diffractometer equipped with the BPC elements can be effectivelly used for a high resolution SANS. In single crystal diffraction the nondispersive arrangement can be adjusted even in case of the different lattice constants d of the monochromator and the sample. In powder diffraction, contrary to the conventional case (a minimum Δd-resolution takes place for $2\tan\theta_S = \tan\theta_M$), by setting a proper monochromator radius $R_M = 2\,L_{MS}/[\sin\theta_M(2 - \tan\theta_M/\tan\theta_S)]$, where L_{MS} is the monochromator-sample distance and $2\theta_M$ is the monochromator take-off angle, the minimum of the Δd-resolution can be shifted to higher scattering angles $2\theta_S$. Then, combined with super-mirror guides and PSD focusing devices may represent a new generation of thermal neutron-scattering instruments which make optimal use of the available neutron flux and achieve high intensities and excellent resolution. Examples of the powerful use of the Bragg diffraction optics for routine neutron scattering experiments in diffractometers of NPI Øež, KURRI Kumatori and PTB Braunschweig will be demonstrated.

P06.14.004 NONCOMMUTATION OF PAULI SPIN OPERATORS DUE TO BALANCED GEOMETRICDAL AND DYNAMICAL PHASES. Y. Hasegawa* and G. Badurek, Institute of Nuclear Physics, Vienna University of Technology, Stadionallee 2, A-1020 Wien, Austria.

Neutron spin polarimetry, which is essentially grounded on the application of Pauli spin operators, has turned out as a powerful tool to clearly demonstrate or even to verify some of the foundations of quantum mechanics. We performed a neutron polarimetric experiment to demonstrate the noncommutation properties of the Pauli spin operators. The polarization of the transmitted neutron beam depends upon the sequential order of two successive spin flip devices with mutually inclined precession axes. It is shown that the phase shift caused by the two successive spin rotations carries specific information about the intermediate state and finally results in the well-known commutation relation of Pauli spin operators. Furthermore, an interpretation of the observed results is presented in terms of an intrinsic phase shift between two interfering mutually orthogonal spin states, which in a sequence of two successive spinor transformations stores particular information about the intermediate state. We discuss this phase shift with respect to its geometrical and dynamical components and its formal connection with the non-commuting properties of Pauli spin operators is explicitly shown.

P12.14.001 PERFORMANCE EVALUATION FOR MULTILAYER OPTICS USING RAY TRACING METHOD. Boris Verman, Karsten Dan Joenson, and Licai Jiang, Osmic, Inc., 1788 Northwood, Troy, Michigan, USA.

A novel multilayer beam conditioning optic, called Confocal Max-Flux® (CMF) Optics, was proposed and tested for hard x-rays in the last two years [1]. These new optics have been applied to a variety of applications such as x-ray diffraction and small angle x-ray scattering. Experimental evidence has shown that flux and many other system parameters are significantly improved by using CMF optics. This paper will discuss the performance evaluation of CMF optics by means of ray tracing compared against experimental results.

The performance of the optical systems studied depends on many factors including the optical layout, multilayer characteristics, x-ray source characteristics and specific applications. In this paper, the source model is described first, then the performance of some standard ideal CMF optics are discussed. Special attention is paid to obtaining parameters relevant for various applications: beam width, flux, divergence etc. The effect of optical imperfections such as curvature and d-spacing errors are discussed, and related to present state-of-the-art capability. Finally the authors will discuss possible improvements to current optics and propose new optics for different applications.

P12.14.002 LOWERING TAILS OF DIFFRACTION PROFILES. Go Fujinawa, X-ray Research Laboratory, Rigaku Corporation, H. Toraya, Ceramics Research Laboratory, Nagoya Institute of Technology, and J. L. Staudenmann, Physics Department, National Institute of Standards and Technology.

Parallel-slit analyzer (PSA) was developed for lowering tails of profiles in powder and thin-film diffraction. Four kinds of foil materials, sintered and hot-pressed tungsten (W), cold worked

stainless steel (SUS) and Be-bronze ($Cu_{4\ 98}Be_{4\ 2}$), and chemically surface-processed Be-bronze (CuO_x) were used for constructing PSA's. They were tested in a parallel-beam geometry using CuKα radiation collimated with a graded *d*-spacing parabolic multi-layer. The W- and CuO_x-PSA's gave the pseudo-Voigt profiles of ~80% Gaussian for direct beam. Rough surfaces of sintered and hot-pressed W and chemically surface-processed CuO_x foils are considered to be effective for depressing the total reflection on the surfaces of foil materials, and consequently for lowering the tails of diffraction peaks.

P12.14.003 MONOCRYSTAL X- RAY OPTIC ELEMENTS. N.Yu.Strelnikova, V.V.Lider, M.V.Kovalchuk [1], N.V.Zhavoronkov [2], [1] Institute of Crystallography RAS, Leninsky pr. 59, 117333 Moscow, Russia, [2] Research Institute of Material Science and Technology, 103460 Moscow

Crystal monochromators and analyzers are widely used for structural characterization of solid matter utilizing X- ray tubes or synchrotron radiation (SR). Institute of Crystallography RAS and Research Institute of Material Science and Technology had gained great experience in parameter calculations of separate optical elements and their assembles [1], their manufacture and characterization. This monocrystal X- ray optic elements are [2]: flat symmetric and asymmetric monochromators for X- ray beam of desired angle- and spectral divergence formation; monolithic grooved monochromators for X- ray beam formation without changing the direction of primary beam and (or) for forming the beam with homogeneous angle intensity distribution; flat triangle monochromators for X- rays focusing; monochromators of complicated configurations for sagittal focusing; water- cooled monochromators of different configurations [3] for effective SR beam thermoloading elimination.

P12.14.004 DOUBLE CRYSTAL MONOCHROM-ATORS FOR SYNCHROTRON RADIATION. Yu.N.Shilin, V.A.Shishkov, M.V.Kovalchuk, V.V.Lider, S.I.Zheludeva Institute of Crystallography RAS, Leninsky pr. 59, 117333 Moscow, Russia

Double crystal monochromator for synchrotron radiation (SR) was designed to provide smooth change of X- ray beam energy in wide range without exit beam position changing, and higher harmonics suppretion [1]. Three modifications of monochromator are proposed: Model 1. X- ray beam energy change is realized by translation of Bragg axis of second crystal-monochromator along horizontal guide in the SR beam direction. Model 2. Horizontal translation of both crystal - monochromators is provided. This design permits to enlarge the changeable exit beam energy region (see Table). Model 3. As the model 1, has only one movable Bragg axis, but is more compact at the cost of the soft X- ray spectrum region (less required than the hard one). All modifications are remote- controlled and supplied with vacuum chambers; modules of second crystal- monochromator are high- precision torsion goniometers with piezodriver; there are possibilities of water- cooling of the first- and sagittal curvature of the second crystal-monochromator.

	Model 1	Model 2	Model 3
Region of Bragg angle	5 - 80°	3 - 87°	5 - 25°
Region of exit Si(111)	2.01 - 23	1 .98 - 38	4 .7 - 23
Beam energy (keV) Si(311)	3.85 - 44	3.79 - 72	9.0 - 44
Region of translation (mm)			
1-st crystal	0	715	0
2-nd crystal	640	715	365
Max. dimensions of crystals	60x80x10 mm3

P12.14.005 DIAMOND MONOCHROMATOR-SPLITTER FOR SYNCHROTRON RADIATION WITH IMPROVED REFLECTIVITY. V.V.Lider, L.V.Samoilova, M.V.Kovalchuk, S.I.Zheludeva. A.V.Shubnikov Institute of Crystallography RAS, Leninsky pr. 59, 117333 Moscow, Russia.

The thermoelastic tolerance and transparency for X- rays of diamond crystals are the main reason to use them as powerful synchrotron radiation (SR) beam monochromators and splitters [1,2]. One of their disadvantages is low scattering capacity. Studying results [3] to avoid this drawback it is proposed to use diamond crystalline plate with thin damaged layer as a monochromator. Layer is formed on the entrance surface by mechanical grinding and polishing. Applying symmetrical Laue reflection (422) and $Mo_{K\alpha}$ radiation the experimental value of integral intensity of X- ray beam, diffracted on diamond plate 0.9mm thick was 2.5 times larger, than the theoretical one. At the same time the intrinsic FWHM of the rocking curve was 1.3 sec.of arc. This value shows that energy resolution of this optical element is still good enough ($\Delta E/E = 1.1x10^{-5}$).

X- ray diffractometry applying several Bragg reflections with different asymmetry showed, that thickness and mosaic spread of the damaged layer are equal to 3μm and 19 sec of arc.

Apparently it is worth while to design damaged layer with optimal parameters for getting maximum integral intensity of diffracted beam. The low value of energy resolution in some cases (f.e., X- rays focusing [2]) should not be considered as limiting factor.

P12.14.006 A VERSATILE FOCUSING MONOCHROMATOR FOR THE D8 ADVANCE. Lange, J., Menges, G. and Kern, A., Bruker Analytical X-Ray Systems GmbH, Östliche Rheinbrückenstraße 50, 76187 Karlsruhe, Germany

The D8 ADVANCE goniometer allows the easy component exchange and precise movement of X-ray optics, X-ray tube and detectors along high precision dovetail tracks. Following this concept a versatile focussing primary monochromator was developed to make measurements possible in different diffraction geometries. By sliding the tube monochromator unit along the primary dovetail track you can change from transmission over capillary to reflection mode. So you have the flexibility to meet any analytical challenge by optimum signal-to-background ratio, maximum stability, high resolution and best performance and a minimum of alignment.

This concept and instrument features will be presented. Furthermore measurements in different diffraction geometries and typical applications will be presented and discussed.

P12.14.007 A MONOLITHIC MONOCROMATOR-COLLIMATOR FOR X-RAYS. C. Ferrari, C.N.R. Maspec Institute, Area Parco delle Scienze 37/A, 43010 Fontanini, Parma, Italy, and D. Korytar, Institute for Electrical Engineering S.A.S., Vrbovska cesta 102, 92191 Piestany, Slovakia .

A new design for a monolithic monochromator-collimator based on Germanium or Silicon defect free single crystals is presented. On the same crystal block four coplanar diffractions take place obtaining an exit X-ray beam in the direction of the incident beam. By using a conventional copper X-ray tube as a source a wavelength dispersion $\Delta\lambda/\lambda$ lower than 10^{-4} and a final divergence of 10 seconds of arc can be achieved. With respect to existing high resolution monochromators, based on multiple diffractions from two distinct channel cut crystals, the present device offers the advantage of a more compact design and of an easier alignment with comparable intensity of the exit X-ray beam.

The use as an accurate tool for X-ray optics with synchrotron radiation is proposed.

P12.14.008 THE APPLICATION OF GRADED MULTILAYER OPTICS IN THE DIFFRACTED X-RAY BEAM D. Bahr, L. Brügemann and R. Stömmer Bruker-AXS GmbH, 76181 Karlsruhe, Germany

Since years now the Göbel mirror is a well known optical component for X-ray diffraction investigations. The mirror provides a parallel and pseudo monochromatic X-ray beam incident on the sample. The optimum benefit of these parallel beam conditions is achieved by using the same kind of optics in the diffracted beam, too.

We will point out the principles of the diffracted beam Göbel mirror and will describe the advantages of this optical component in comparison to classic parallel beam optics. Several measurement examples from various applications presented will explain which method of investigation benefits from the diffracted beam Göbel mirror.

P13.14.000 THE ATS SCATTERING OF IRON PYRITE AND MAGNETITE. K. Ishida, M.Kanazawa, K.Hagiwara, K. Horie, J. Kokubun, Department of Physics, Faculty of Science and Technology, Science University of Tokyo, Noda, Chiba 278-8510, Japan.

Near an absorption edge, anisotropic effect of tensorial atomic scattering factor becomes so large that reflections forbidden by screw or/and glide rule can be observed (ATS reflections)[1]. ATS reflections were observed in some crystals with synchrotron radiations[2-5]. We measured energy dependence of ATS reflection intensity of pyrite (FeS2) and magnetite (Fe3O4) near the Fe K-absorption edge.

For a pyrite crystal, the observed energy spectra are quite different from that of the absorption measurement. In the region above the edge, the ATS intensities for (001), (003) and (011) reflections showed the same energy dependence, two sharp and one broad peaks. To study nature of the scattering, we measured polarisation property and azimuthal dependence of the reflections. The result can be understood on the basis of electric dipole transition. But below the edge, the energy spectra of the ATS intensity depend on the reflection plane. The azimuthal dependence of the intensity cannot be explained by the calculation based on only the dipole transition. Quadrupole transition may contribute to the scattering. While, for a magnetite crystal, there are two peaks above and below the edge, which are also different from the absorption experiment. The azimuthal dependence of the peaks can be explained by dipole transition. The energy spectrum of the scattering measured at 80K was almost the same as that at room temperature except for an additional intensity enhancement due to the structural transition.

P13.14.001 INVERSION OF DYNAMICAL FAST ELECTRON ELASTIC SCATTERING FROM CRYSTALS. A.E.C. Spargo , L.J. Allen, School of Physics, University of Melbourne, Parkville 3052, Australia and H. Leeb, Institut fur Kernphysik, Technische Universtat Wien, Vienna, Austria.

The retrieval of a unique crystal potential from the scattering matrix in high energy transmission electron scattering has been achieved, at least in principle. It is shown that data recorded at a single crystal orientation are, in general, not sufficient to determine all the elements of the matrix. Additional measurements with defined tiled beam are required for the determination of the entire matrix. Extraction of the crystal potential from the scattering matrix can be achieved using equations of constraint defined by the principal orientation and/or a set of linear equations that reflect the symmetry of the fundamental (Bethe) matrix when written in an appropriate form.

P13.14.002 FORBIDDEN REFLECTION NEAR EDGE DIFFRACTION OF INCOMMENSURATELY MODULATED STRUCTURE Rb_2ZnCl_4. K. Matsuoka, S. Kuwajima, S. Nagao and Y. Soejima, Department of Physics, Kyushu University, Fukuoka 812-8581, Japan

Intensity distribution in reciprocal space of forbidden reflection near edge diffraction (FRED) due to the anisotropy of tensor of susceptibility (ATS) has been determined for Rb_2ZnCl_4. The measurements are made as a function of incident X-ray energy around the Rb K absorption edge, and also as a function of temperature through the normal/incommensurate and incommensurate/commensurate phase transitions. It is found that, on the 041 forbidden reflection of the incommensurate structure, the FRED intensity appears at two slightly separate positions in reciprocal space, and at two incident energies. It is observed that one of the two FRED intensities disappears in the normal phase, and the other one does in the commensurate phase. The results indicate that the anisotropy of electron distribution in Rb atom is different in the normal and commensurate phases, and that the two kinds of anisotropy coexist in the incommensurate phase. Accordingly, we conclude that the FRED intensity is strongly related to the structure, and the intensity distribution is affected by the incommensuration. A theoretical study on the X-ray resonant scattering in the incommensurately modulated structure has been reported by Ovchinnikova & Dmitrienko (to be published in Acta Cryst.). It is to be hoped that theoretical explanation of the present experimental results will be given.

P13.14.003 RESONANT X-RAY DIFFRACTION BY MODULATED CRYSTALS. E.N.Ovchinnikova, Physical Department of Moscow State University, Moscow 119899, Russia and V.E.Dmitrienko, Institute of Crystallography, 59 Leninski pr., 117333, Moscow, Russia

We consider conditions for the appearence of additional ("forbidden") reflections owing to the anisotropy of anomalous X-ray scattering by modulated crystals. These reflections are forbidden in the diffraction pattern far from the absorption edges and can be observed only with the synchrotron radiation. It is shown that the modulation (displacive or occupational) can change the local symmetry of atomic environments and hence becomes a source of additional anisotropy for each resonant scatterer inducing the modulated behaviour of susceptibility

tensor. The modulation can change both the resonant spectra and the tensorial properties of susceptibility. The four-dimensional approach is used to calculate the set of possible reflections near the absorption edges in the case of incommensurate modulation [1]. This approach allows to show that no additional reflections can appear owing to the variation of the resonant spectra in the resonant X-ray diffraction by incommensutately modulated crystal in opposite to the case of commensurate modulation. The additional reflections can appear owing to the modulation of the angular part of the susceptibility. It is found, that both a system of forbidden main reflections and forbidden satellites can occur even in those cases when the resonant atoms in fundamental structure are located in position with cubic local symmetry. These reflections correspond to glide planes, screw axes and centering translations in four-dimensional space. Symmetry restrictions on the intensities and polarization properties of forbidden main reflections and satellites are found for incommensurately modulated crystals. It was shown that the properties (such as azimuthal and polarization dependencies) of main forbidden reflections can differ >from those of forbidden satellites and they depend on the modulation type in a crystal. The comparison of the azimuthal dependences of main forbidden reflections and satellites would allow to calculate the correction to the susceptibility, which appear due to the modulation. The crystal structures in which the listed effects can be observed are presented, for example the additional reflections near the K-edge of Ni in diffraction pattern of La_2NiO_{4+x}.

P13.14.004 X-RAY DOUBLE AND QUADRUPLE PHASE RETARDER SYSTEMS COMPENSATING SPHERICAL AND CHROMATIC ABERRATIONS. K. Okitsu, University of Tokyo, 2-11-16 Yayoi, Bunkyo, Tokyo 113-8656 Japan, Y. Ueji, The Graduate University for Advanced Studies, 1-1 Oho, Tsukuba, Ibaraki 305-0801 Japan, K. Sato and Y. Amemiya, University of Tokyo, 7-3-1 Hongo, Bunkyo, Tokyo 113-8656 Japan.

The transmission x-ray phase retarder [1] developed by Hirano, Ishikawa and Kikuta is widely used as a decisive x-ray optical device for controlling polarized states of x ray beam. However, it has a problem of phase-shift aberration due to angular and energy spread of incident x rays when a high degree of pure polarization state is required.

In order to overcome this problem, we have developed an x-ray double phase retarder system which can compensate the spherical aberration. The system is composed of two phase retarders which are set so as to give Bragg reflections in the opposite directions. We could obtain a vertical linear polarization with a 99 % of P_l ($=I_v$-I_h/I_v+I_h) from horizontally polarized x rays with this system. This value favourably compares with 85 % which was obtained by a single phase retarder with the same total thickness. The double phase retarder system has been used for the switching of the helicity of circular-polarized x-rays, with which the x-ray natural circular dichroism (XNCD) has been successfully measured in the vicinity of Ni *K* absorption edge. (see Ueji *et al.* at the present congress).

Furthermore, we have developed an x-ray quadruple phase retarder system which can compensate both spherical and chromatic aberrations. This system consists of four transmission phase retarders whose scattering planes are inclined by α, α +90, α +180, α +270 degrees from the polarization plane of the incident linearly polarized x rays.

P13.14.005 DARWIN'S METHOD IN THE THEORY OF X-RAY DYNAMICAL DIFFRACTION IN DISTORTED CRYSTALS AND IMPERFECT CRYSTALLINE MULTILAYERED STRUCTURES. I.R.Prudnikov, Physics Department, M.V.Lomonosov Moscow State University, Moscow 119899, Russia.

At present, the approach based on the recursion equations for the amplitude reflection and transmission coefficients of individual layers is widely used in theoretical studies and computer simulation of X-ray diffraction in layered crystals and multilayered materials. The recursion equations were first obtained by Darwin [1] for solving the problem of dynamical diffraction by perfect crystals. In the paper Darwin's method is extended to the case of X-ray dynamical diffraction in distorted crystals and imperfect multilayered structures where the deformation field and the polarizability are functions of three coordinates (x, y, z) of the point inside the sample. We have derived the recursion equations describing three-dimensional dynamical diffraction in these crystals and structures. We have considered both Bragg-case diffraction [2] and Laue-case diffraction. On the basis of the obtained recursion equations we have developed algorithms for computer simulation of X-ray dynamical diffraction in structures with a spatial modulation of crystal lattice parameter and/or the polarizability (e.g., multilayered structures with lateral periodicity, a crystal under surface acoustic wave excitation, porous materials). The above results make it possible to map the angular distribution of diffraction intensity near reciprocal-lattice points. In the paper we give numerical examples of calculated reciprocal space maps. Advantages and limitations of the above approach in comparison with the well-known approaches of the dynamical diffraction theory are discussed.

P13.14.006 INTERFERENCE PATTERNS FROM SEMI-INFINITE AND FINITE CRYSTALS. H.B. Larsen and G. Thorkildsen, Department of Mathematics and Natural Science, Stavanger College, Ullandhaug, 4004 Stavanger, Norway.

A theoretical investigation of X-ray interference patterns from semi-infinite and finite perfect crystals has been undertaken. By using the boundary value Green function technique along with the Takagi-Taupin equations [1], expressions for the diffracted intensity pattern at the exit surfaces of a *t* ×*l* crystal have been derived. The formalism is general and enables the study of different types of waves (plane, spherical and point source) impinging the crystal. In addition, the effect of varying the width of the incoming beam by slits is modelled. Anomalous absorption is taken into account using complex expansion parameters. In the corners of a semi-infinite crystal the standard Borrmann-Lehmann interference pattern [2,3] is retrieved. The present approach includes the possibility of non-symmetrical reflections and utilizes the full Bessel-function representation for the fields. Simulations for a variety of $t \times l$ crystal geometries have been performed using diamond as a model system. The results are described by assessing the contributions from the various geometrical scattering regions formed within the crystal. For a crystal of finite size this may lead to a more complex pattern owing to the possibility of an increased number of such regions. Both reflection and transmission modes are addressed. The simulated interference patterns are significantly influenced by minor changes of the input parameters, thus reflection asymmetry, positioning of source point and slit size *etc.* play crucial roles when interpreting such patterns.

P13.14.007 APPLICATION OF STATISTICAL DYNAMICAL THEORY TO X-RAY DIFFRACTION PROFILE BY DOUBLE-CRYSTAL METHOD. T. Takama and M. Miyazawa, Faculty of Engineering, Hokkaido University, Kita-ku, Sapporo 060-8628, Japan.

Kato constructed the statistical theory of dynamical diffraction [1] based upon the equations of Takagi-Taupin. It describes an X-ray wave-field and an integrated intensity in a distorted crystal with defects statistically distributed over the volume. The theory was further developed to explain the angular distribution of the diffracted intensity by Bushuev [2]. In the present study, the latter theory is applied to analyze the X-ray profiles measured for Si with micro-defects. The micro-defects of SiO_2 distributed over the volume were introduced into Cz-Si wafers by annealing in Ar gas at 1223K for 25 to 260 hr. The angular distribution of the diffracted intensity on the symmetrical Laue case was measured by double-crystal method using Mo Kα. The measurements were performed for the (400) reflection. The width of the profile increased with an increase in the heating time. A shoulder in the intensity was observed at higher side of the Bragg angle for longer time annealing. In the analysis we assumed that the crystal consists of mosaic blocks disoriented with an angular distribution function W. In addition, the correlation length of wave-fields was assumed to be ten percent of the correlation length of the phase factor. We utilized the values of the static Debye-Waller factor measured for the same samples by the Pendellosung fringes method [3]. The calculated profiles were compared with the experiments. The results showed that the model describes fairly well the measured angular profiles including the shoulder in intensity, when the function W has the form of exp(-a/δ)/2δ. For example, the value of δ was 2.1 sec in arc for 260 hr annealing. When the Gaussian distributiopn was employed for W, the theory did not explain the profiles.

P13.14.008 ON THE FEASIBILITY OF TRIPLET PHASE DETERMINATION FROM NON-PERFECT CRYSTALS. J. Zellner, E. Weckert, R. Müller, Institut für Kristallographie, Universität Karlsruhe (TH), D-76128 Karlsruhe, Germany and M. Drakopoulos, A. Snigirev, ESRF, F-38043 Grenoble, France.

Three-beam interference experiments have been carried out successfully with crystals of a number of different compounds ranging from small molecule structures to quasicrystals and protein crystals [1]. The invariant triplet phase $\phi_T = \phi(\mathbf{g})+\phi(\mathbf{h}-\mathbf{g})-\phi(\mathbf{h})$ can be determined by the three-beam interference which forms a characteristic intensity modulation. The methods main drawback, however, is the requirement of crystals with very low mosaicity.

To overcome this problem, two methods have been investigated: **1.** In case of mosaic crystals showing well separated blocks the very parallel synchrotron beam can be used to select only a single block for the three-beam interference experiment. This technique requires the exact knowledge of the mosaic distribution which can be determined by the characterization of the mosaic structure using *reciprocal space tomography*. **2.** In addition to this 'reciprocal space' separation of single mosaic blocks the availability of high resolution CCD cameras [2] enables a real space separation of crystal blocks by on-line topography like techniques.

Experiments were carried out on samples of the semi-conductor material silicon carbide SiC and a non-perfect decagonal quasicrystal $Al_{70}Ni_{15}Co_{15}$.

P13.14.009 SECONDARY EXTINCTION IN CYLINDRICAL AND SPHERICAL CRYSTALS FOR X-RAY AND NEUTRON DIFFRACTION. Hua-Chen Hu, China Institute of Atomic Energy, Graduate School of Nuclear Industry, P. O. Box 275(18), Beijing 102413, People's Republic of China.

Based on the study of extinction in plane crystals (Hu,1997), a systematic investigation of secondary extinction and integrated intensity for absorbing cylindrical and spherical crystals has been carried out by more accurate numerical calculation for all Bragg angle θ_B range (0°-90°) and samples with reduced radius $\Sigma_s R$ from 0-20 and absorption to scattering cross section ratio μ/Σ_s from 0-8. Many new and hitherto unsuspected effects are obtained, particularly for large extinction. We find that: 1. A minimum appears in the extinction factor Y *versus* $\Sigma_s R$ curves for $\mu/\Sigma_s > 0$ when $\theta_B > 0^\circ$. The dip is more pronounced for μ/Σ_s between 0.5 and 1.0 and $\theta_B < 45^\circ$. 2. The shape of the Y *versus* θ_B curve changes considerably with $\Sigma_s R$ or μ/Σ_s. Thus a dramatic increase of the extinction factor with increasing θ_B from 0°-20° appears when $\Sigma_s R > 5$ and $\mu/\Sigma_s > 0.5$. 3. When the extinction factor of a sphere is compared with that of a cylinder of the same radius, the Y value for the sphere is usually larger than that of the cylinder, and conversely when $\mu/\Sigma_s > 1$ and $\Sigma_s R > 5$. These behaviors originate in a complex combination of Laue and Bragg geometries and the rather sensitive dependence of the extinction on θ_B and μ/Σ_s for a large crystal. We believe that none of them would be found if absorption and scattering were treated separately. The intensity distribution of the exit beam from a cylinder for both multiple and single reflection is also evaluated for the first time. The later being directly related to the mean path length T_μ in conventional extinction theory. One can estimate from these curves that for the same μ and R the mean path length in the multiple reflection case is shorter than that of single reflection case and the difference is more pronounced for small μ/Σ_s and large R. The effect on Y for different shapes of mosaic distribution will also be discussed.

P13.14.010 QUANTITATIVE DETERMINATION OF TRIPLET PHASE INVARIANTS: UNIVERSALITY OF THREE-WAVE PEAK PROFILES. C.H. Chao and S.L. Chang, Department of Physics, National Tsing Hua University, Hsinchu,Taiwan 30043, ROC and Synchrotron Radiation Research Center, Hsinchu, Taiwan 30077, ROC. and Yu.P. Stetsko, Department of Physics, National Tsing Hua University, Hsinchu, Taiwan 30043, ROC and Chernovtsy State University, Chernovtsy 274012, Ukraine.

The procedure for quantitative determination of the triplet phase invariants is proposed, based on the comparison of the peak intensities of two symmetry-related three-wave X-rays diffractions. The procedure maps the three-wave peak profiles into a set of the dimensionless universal curves. The geometrical interpretation of the value of triplet phase invariant is given. A method for the determination of the zero point and the width of the measured three-wave peak profile is also proposed. The approbation of the procedure on the dynamically calculated peak profiles with the specified values of phase invariants as well as on the experimentally measured peak profiles for several organic and macromolecular crystals with known values of phase invariants is

carried out. The determined values of the triplet phase invariants are in good agreement with the above mentioned values.

P13.14.011 INELASTIC NEUTRON SCATTERING BY ULTRA -SOUND IN CRYSTALS. EXTINCTION EFFECTS. E.Iolin, E.Raitman, L.Rusevich, Institute of Physical Energetics, Riga, LV-1006, Latvia and B.Farago, Institute Laue-Langevin, BP-156, F-38042 Grenoble Cedex 9, France and F.Mezei, Hahn-Meitner Institute, 14091 Berlin, Germany.

We have observed, for the first time, inelastic neutron scattering (INS) from phonons (AW) externally excited in single crystals. We have used ultrasonic transducers (f_S=30 - 200 MHz) for exciting and Neutron Spin Echo (NSE) spectroscopy for the observation AW. It allowed us to trace the evolution of the elastic Bragg intensity I(0) and of the phonon harmonics Ih(n) up to n=7 as a function of the excitation power P in perfect and deformed Si. In deformed Si I(0) strongly decreases at low P. These results are in agreement with dynamical theory calculations. At the highest power we observed a cross-over to a chaotic phonon behavior. Rapid decay of NSE signal was described here by means of model of quasi mosaic crystal. For the case of classical mosaic crystal KBr we found new secondary extinction effect. Mosaic block is vibrated as a whole in the AW (we suppose that $\lambda_S >> L$, L is linear block dimension). The exchange of small energy ~ 0.6 μeV between AW and cold neutron (λ≈0.54 -0.57 nm) leads to the deviation of neutron impulse from the Bragg position at the value $\delta k_i = 2\pi f_S /(v \sin(2\Theta_B))$ (v -neutron velocity). If $\delta k_i L \geq \pi$ elastic and one-phonon scattering are realized in the different parts of the impulse space in the *one* mosaic block. Therefore secondary extinction for the elastic and inelastic scattering should be considered separately and ultrasound leads to the increasing of the *total* intensity of scattering Iht in the crystal with moderate (several μm) size of mosaic blocks. Results of secondary extinction calculations are in a good agreement with the results of our NSE experiment with KBr (f_S=111 MHz). We clearly observed INS in the strongly excited pyrolitic graphite (λ_S ≈60μm). However the effect of the AW at Iht was absent. Condition $\delta k_i L \geq \pi$ wasn't fulfilled due to the bad structure of PG. It seems that similar experiments could be applied for the estimate of the size of the mosaic blocks even without application of NSE technique.

P13.14.012 THICKNESS DEPENDENCE OF X-RAY INTEGRATED INTENSITY FROM SILICON CRYSTALS WITH DISLOCATIONS. D. Sakaki and T. Takama. Faculty of Engineering, Hokkaido University, Kita-ku, Sapporo 060-8628, Japan.

One of the urgent problems in the diffraction crystallography is to establish the accurate method for extinction correction applicable to distorted crystals with arbitrary imperfection. The answer was given by Kato as the statistical dynamical theory [1]. It has been revised and developed by many investigators. The theory was tested experimentally by comparing the observed integrated intensities with the theory [2], [3]. The tests showed that the correlation length of the amplitude G is much shorter than the Kato proposal that G is equal to L/E (L: extinction distance). These experimental tests were performed only for crystals with relatively high perfection with the static Debye-Waller factor E close to 1. In the present study, crystals with dislocations are selected for test sample and the measured intensities are compared with the theory.

The parallel-sided Si single crystals with dislocation densities of 600 and 10^6/cm^2 were prepared. The X-ray integrated intensities of the (220), (400) and (440) reflections were measured by a four-circle diffractometer using Mo Kα as a function of crystal thickness by changing the effective thickness using the φ inclination method. The thickness fringe disappeared for the crystals. The measured intensities were compared with the theory and the values of E, G and the correlation length of the phase factor τ were determined for each sample by the least-squares method. The values of E ranges from 0.1 to 0.52 depending on the reflection plane and the dislocation density. On the other hand, τ has the length with the same order as the previous result [3]. The value of G, however, had length with the same order as the extinction distance. This indicates that the detail study for G is needed to apply the theory for the extinction correction and characterization of crystal.

P13.14.014 SPECIMEN ABSORPTION CORRECTION FOR DIFFRACTION EXPERIMENTS WITH AREA DETECTOR SYSTEMS. S. Scheidegger, M.A. Estermann and W. Steurer, Laboratorium fur Kristallographie, Eidgenoessische Technische Hochschule, ETH-Zentrum, CH-8092 Zurich, Switzerland.

Methods, dedicated to two-dimensional area detector systems and broad diffuse scattering phenomena, for correcting specimen absorption in X-ray diffraction experiments are implemented and tested. The respective transmission factors, in relation to the crystal or specimen shape, are applied to the intensity of every pixel of the two-dimensional detector. This is in contrast to routine data reduction where the transmission factors are applied to the integrated Bragg intensities only. Single-crystals and amorphous specimen are treated the same way. This allows for a fully quantitative treatment of continuous diffraction information, such as diffuse scattering or amorphous scattering, which is collected with a two-dimensional detector system. Furthermore, it is possible to assign different linear attenuation coefficients to the paths of the incident and scattered beam, as is desirable, for instance, in the case of X-ray holography with an internal resonant scatterer. To test the pixel-wise approach, the continuous scattering from an amorphous lead-glass specimen of defined shape is utilised. Synchrotron radiation was used to study in detail the influence of experimental parameters onto the accuracy of the pixel-wise absorption correction, and we will present the results of numerical calculations.

P13.14.015 THREE-WAVE X-RAY DIFFRACTION: POLARIZATION ASPECTS OF PHASE SENSITIVITY. Yu.P. Stetsko, Department of Physics, National Tsing Hua University, Hsinchu, Taiwan 30043, R.O.C. and Chernovtsy State University, Chernovtsy 274012, Ukraine. S.L. Chang and Y.S. Huang, Department of Physics, National Tsing Hua University, Hsinchu,Taiwan 30043, R.O.C. and Synchrotron Radiation Research Center, Hsinchu, Taiwan 30077, R.O.C.

A model of analyzing the phase sensitivity of the reflection coefficients of diffracted waves in the case of three-wave X-ray diffraction is proposed. This model considers three-wave diffraction as the interference of the directly and the "Umweg" - excited diffracted waves and seems to properly account for the phase sensitivity, as well as the behavior of an involved diffracted wave as a function of the triplet phase invariant, the polarization state of the incident wave, and the

diffraction geometry. Dependence of the three-wave peak profiles of the diffracted wave on the polarization of the incident and diffracted waves is investigated. General conditions of change of the peak profile asymmetry as well as conditions of high phase sensitivity of peak profiles are obtained. Good agreement between theoretical and experimental results is shown. Consideration on practical issues for phase determination is also given.

P13.14.016 X-RAY STANDING WAVE METHOD UNDER MULTI-BEAM DIFFRACTION CONDITION. M.V.Kovalchuk, L.Samoilova, A.Kreines, A.Zozulja Institute of Crystallography RAS, Leninsky pr. 59, 117333 Moscow, Russia

Full crystallographic characterization of the thin film structure and buried layers in single crystals requires two-dimensional determination of atom position. This can be achieved by combining of the X-ray standing wave (XSW) method with multi-beam diffraction [1,2]. In this presentation formation and behavior of X-ray wavefields in crystal are studied under condition of three-beam diffraction in Bragg geometry experimentally and theoretically. Numerical simulation based on multi- beam dynamical theory was used to determine principal scattering parameters and X-ray wavefield attenuation with depth and study its modulation in the directions of diffraction vectors. In XSW technique X-ray fluorescence and photoelectrons are often used as secondary process. Photoelectron escape depth is less than X-rays penetration depth under dynamical diffraction condition (so-called extinction length) and probability of photoelectron yield is proportional to XSW field intensity at atomic position. So photoelectrons can play a role of very sensitive probe to observe the two-dimension XSW intensity distribution in thin subsurface layer. One of the advantages of multiple diffraction is its phase sensitivity. So XSW method under multiple diffraction condition can be realized without measuring of any secondary radiation [3]. The experimental XSW studies of semiconductor single crystals under multi-beam diffraction condition will be presented in detail.

P13.14.017 PHASE SENSITIVE DIFFRACTION FOR ONE DIMENSIONALLY DISTORTED CRYSTALS. Klaus Schroer[a,b], Kerstin Hölzer[a,b], Edgar Weckert[b], and Kurt Hümmer[b], [a]Biology Department, Brookhaven National Laboratory, Upton, New York 11973, USA, [b]Institut für Kristallographie, Universität Karlsruhe (TH), D-76128 Karlsruhe, Germany.

For ideal single crystals only the integrated intensities of discrete reciprocal lattice points must be collected in order to solve the atomic structure. In contrary for layered samples and surface structures intensity profiles have to be measured as a continues function of the position in reciprocal space around and between the reciprocal lattice points respectively.

It was shown for single crystals that three-beam interference experiments can be used to get phase information by determining the triplet phase of the contributing reflections [1]. The application of this technique to layered samples consisting of semiconductor materials has been investigated [2]. An algorithm based on the Takagi equations has been developed to simulate the resulting interference profiles. The influence of different system parameters (layer thickness, lattice strain) on the form of the interference profiles was determined in theoretical calculations.

Experiments were carried out on SiGe and SiC layers of different thickness grown on Si. The intensity change for different positions on the rocking curve of a primary reflection due to the interference with a substrate reflection was recorded for several three-beam cases. When moving to different positions on the rocking curve of one of the contributing reflections, in the interference profiles one can see clearly a shift of the "triplet phase", which shows that it can be described as a continues function of the reciprocal lattice coordinates. Using the Takagi algorithm the measured interference profiles were simulated and showed a good agreement between the measurements and the theoretical predictions.

P13.14.018 SYNCHROTRON RADIATION X-RAY MULTIPLE DIFFRACTION APPLIED TO THE STUDY OF ELECTRIC FIELD INDUCED STRAIN IN MBANP ORGANIC NONLINEAR OPTICAL CRYSTALS. L. H. Avanci[1], L. P. Cardoso[1], S. E. Girdwood[2], D. Pugh[2], J. N. Sherwood[2], J. M. Sasaki[3,4], K. J. Roberts[3]. [1]IFGW/Universidade Estadual de Campinas, 13083-970, Campinas, SP, Brazil; [2]Pure and Applied Chemistry Department, Strathclyde University, Glasgow, G1 1XL, UK; and [3]CMIE/DMCE, Heriot-Watt University, E14 4AS, Edinburgh, UK, [4]Departamento de Física/Universidade Federal do Ceará, 60455-760, Fortaleza, CE, Brazil

In this work, distortions produced in the unit cell of a MBANP [(-)-2-(α-metilbenzilamina)-5-nitropiridina] nonlinear organic crystal under the influence of an applied electric field, E, are investigated by using synchrotron radiation x-ray multiple diffraction (XRMD). The method is based in the inherent sensitivity of this technique to determine small changes in the crystal lattice which provide peak position changes in the XRMD pattern (Renninger scan). A typical Renninger scan shows numerous secondary peaks, each one carrying information on one particular direction within the crystal. The ($hk\ell$) peak position in the pattern, for a fixed wavelength, is basically a function of the unit cell lattice parameters. Thus, small changes in any parameter due to a strain produced by E give rise to a corresponding variation in the ($hk\ell$) peak position and the observed strain is related to the piezoelectric coefficients. The advantage of this method is the possibility of determining more than one piezoelectric coefficient from a single Renninger scan measurement [1]. The method has been applied to the MBANP (monoclinic, point group 2) crystal and we were able to determine four piezoelectric coefficients: $|d_{21}| = 0{,}2(1) \times 10^{-11}$ Vm^{-1}, $|d_{22}| = 24{,}8(3) \times 10^{-11}$ Vm^{-1}, $|d_{23}| = 1{,}3(1) \times 10^{-11}$ Vm^{-1} and $|d_{25}| = 5{,}9(1) \times 10^{-11}$ Vm^{-1}. The measurements have been carried out at the SRS, stations 7.6 and 16.3, Daresbury Laboratory, Warrington, UK.

P13.14.019 OBSERVATION OF HYSTERESIS- LIKE BEHAVIOUR IN mNA ORGANIC CRYSTALS USING X-RAY DIFFRACTION. L. H. Avanci[1], R. S. Braga[1], L. P. Cardoso[1], D. S. Galvão[1] and J. N. Sherwood[2]. [1]IFGW/Universidade Estadual de Campinas, 13083-970, Campinas, SP, Brazil; [2]Pure and Applied Chemistry Department, Strathclyde University, Glasgow, G1 1XL, UK

Recently [1], geometrical distortions produced in the unit cell of a meta-nitroaniline (mNA) under the influence of an applied electric field were investigated and the piezoelectric coefficients determined. This investigation was carried out using synchrotron x-ray multiple diffraction. In the present work we

report first time experimentally observed hysteresys-like behaviour in mNA organic crystals using X-ray diffraction techniques. The mNA crystallises in the orthorhombic system with point group mm2, has 4 molecules per unit cell and lattice parameters a = 6.501 Å, b = 19.330 Å and c = 5.082 Å. The molecule is essentially planar with dipole moment directed from N_1 in the amino towards N_2 in the nitro group and the polar axis of the material is $\boldsymbol{c} \equiv [001]$. From a theoretical point of view we investigated the hysteresis-like behaviour analysing the geometrical distortions of mNA molecules under the influence of an external applied electrical field that can be varied. The calculations were carried out using the well known semi-empirical method AM1 (Austin Method One) with a modified code to explicitly include an external field into the Hamiltonian [2]. The unit cell distortions were detected through the peak shifts in two-beam diffraction case (rocking curves) measured for each field strength. Our results have shown that the experimental data can be explained in terms of changes in the acceptor-donor properties of mNA molecules.

P13.14.020 THE DETERMINATION OF THE ABSOLUTE STRUCTURE OF LOW Z <= 7 COMPOUNDS BY THREE-BEAM DIFFRACTION. K.Hummer, T. Jouffre, R. Muller, E. Weckert and J. Zellner, Institut fur Kristallographie, Universitat Karlsruhe, D-76128 Karlsruhe, Germany

The determination of the absolute structure of compounds containing nitrogen as the heaviest element can hardly be accomplished by standard methods exploiting anomalous dispersion effects. This problem, however, can easily be solved by the experimental determination of triplet phases by means of three-beam interference experiments [1], since this method does not require the presence of anomalous dispersion effects.

Three-beam interferences lead to characteristic intensity changes from which the triplet phases can be deduced [2]. Most suitable for the determination of the absolute structure are triplet phases close to 90 or -90 °.

The results of a number of C-N-H compounds such as $C_{28}N_2H_{20}$ or $C_{23}N_2H_{25}$ as well as O-N-C-H compounds with very low oxygen content will be presented.

P13.14.021 MANY-BEAM X-RAY DIFFRACTION FROM SILICON AT EXACT BACKSCATTERING. J.P. Sutter , Purdue University and Argonne National Laboratory; E.E. Alp, G. Bortel, M.Y. Hu, P. Lee, W. Sturhahn, and T.S. Toellner, Advanced Photon Source, Argonne National Laboratory, Argonne, IL 60439, USA; R. Colella, Department of Physics, Purdue University, West Lafayette, IN 47907, USA; H. Sinn, Fachbereich Physik, University of Rostock, 18051 Rostock, Germany.

We have examined the (12 4 0) reflection in silicon at exact backscattering. It can be shown that for a cubic lattice, if a reflection (HKL) is set to backscattering, all reflections (hkl) for which $h^2+k^2+l^2= hH+kK+lL$ are excited also. As a result, (12 4 0) backscattering in silicon is found to occur with 22 secondary reflections, of which 10 are in the Bragg geometry. An inspection of the backscattering case has been difficult in the past due to the lack of sufficiently monochromatic and tunable X-rays. However, the use of a monochromator of bandwidth 2.3 meV (less than the (12 4 0) backscattering bandpass of 6.2 meV) has made such an inspection possible with a synchrotron X- ray source. We have scanned the backscattered intensity versus the incident angles at the exact backscattering energy (14.438 keV) and at 30 meV above this energy. At certain incident angles, deviations of this intensity from the normally expected values are observed; each of these can be ascribed to the simultaneous excitation of a specific set of secondary reflections. The polarization dependence of these secondary excitations is also studied. Finally, we used a calibrated image plate to gather intensity data on the 10 Bragg-geometry secondary beams. We will compare these data with the predictions made by many-beam dynamical diffraction theory [1] and discuss the implications for backscattering applications.

P13.14.022 NEW PRECISION MEASUREMENTS OF ATOMIC FORM FACTORS USING SYNCHROTRON RADIATION: SILICON, COPPER, SILVER AND GOLD. Z. Barnea, C.Q. Tran, C.T. Chantler, D. Paterson, D.X. Balaic, D.J. Cookson†, School of Physics, University of Melbourne, Parkville, Victoria 3052, Australia. † Chem-Mat-CARS ,Argonne National Laboratory, 9700 S. Cass Avenue, Argonne, IL 60439

Complex X-ray form factors are used in many fields including crystallography, material science, medical diagnosis and XAFS studies. Discrepancies between theories and between experiments of 10% or more over central X-ray energies prevent investigations of new physics and new structural determinations. Until recently, few references claimed experimental accuracies of 1%, and many experts believed that accuracies and precisions below 1% were not possible. We present new experimental measurements with accuracies below 0.3%, and precision of order 0.01%, for attenuation coefficients of Silicon (5keV to 20keV) and of Copper (8.84keV to 20keV), and the latest results from recent experiments at the APS (Chicago). Many sources of error neglected in previous experiments have been carefully investigated. Major discrepancies are systematically addressed with this data and approach.

P13.14.023 NEW THEORY RESOLVING DISCREPANCIES OF ATOMIC FORM FACTORS AND ATTENUATION COEFFICIENTS FOR NEAR-EDGE SOFT X-RAYS. C. T. Chantler, School of Physics, University of Melbourne, Parkville, Victoria 3052, Australia.

Reliable knowledge of the complex X-ray form factor and the photoelectric attenuation coefficient is required for crystallography, medical diagnosis, radiation safety and XAFS studies. Discrepancies between currently used theoretical approaches of 200% exist for numerous elements from 1 keV to 3 keV X-ray energies. This work addresses key discrepancies and derives new theoretical results in near-edge soft X-ray regions [1].

The current result improves upon the theoretical uncertainty in these difficult regions to σ = 20% - 30% and appears to reduce the error of this method to less than one standard deviation. Related work has recently confirmed the importance of theoretical computations of form factors for many experiments in general X-ray regions, with accuracy approaching 1%. This is achieved by this formalism [2].

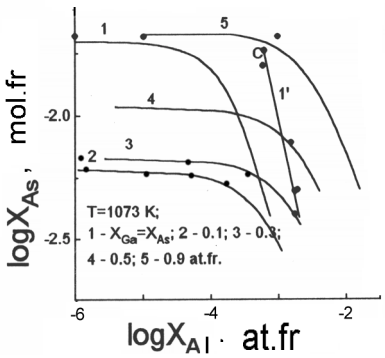
15. CRYSTAL GROWTH – TECHNIQUES, INSTRUMENTATION/APPLICATIONS

P06.15.001 PHASE EQUILIBRIUM AND EPITAXIAL GROWTH IN Bi-Al-Ga-As SYSTEM. Oskomova N.V., Antoschenko V.S., Taurbaev T.I. Optoelectronics Laboratory, Kazakh State University.

LPE of solid solutions in Bi-Al-Ga-As system at $X_{Ga}= X_{Al}$ has not been carried out before. It is explained by the fact that system becomes unstable in case of using pure Bi as a solvent. This leads to heterogeneous dissolution of the substrate and makes epitaxial growth impossible. In the present work the reasons of interphase instability are considered and epitaxial films of AlGaAs grown from Bi-Al solvent are obtained.

Calculations of phase diagrams revealed that the main factor of solid solution/substrate interface instability is abnormally high distribution coefficient of Al in the considered system. This leads to transition of most part of Al to solid phase while approaching the equilibrium and to additional dissolution of the substrate. Analysis of liquidus isotherms showed considerable divergence between experimental and calculated data at $X_{Ga}= X_{Al}$ within narrow interval of concentration of Al. For X_{Ga} exceeding 2 at.% experimental and calculated data are in good agreement (See Fig.). Applying the original techniques of epitaxial growth at this region of composition, it became possible to obtain monocrystalline films AlGaAs of 1-20 mcm of thickness and of good quality separated from the initial substrate by a layer of metal Bi. Crystallisation on the substrate directly took place when it was more than 2 at. % of Ga, added to the liquid phase. It was found that the main condition determining the mechanism of interface relaxation is the intersection of the liquidus isotherm $X_{Ga}= X_{Al}$ with other 'isogallium isotherms'. Phenomenological simulation has been suggested.



P06.15.002 HIGH RESOLUTION X-RAY CHARACTERISATION OF STRAINED SiGe/Si MULTILAYER DEVICE STRUCTURES WITH HIGH Ge FRACTION. J.C. Jones, A.M. Keir, W.Y. Leong, R.T. Carline, G.M. Williams, D.J. Wallis. Defence Evaluation and Research Agency, DERA, St Andrews Road, Malvern, Worcestershire WR14 3PS.

Pseudomorphic $Si/Si_{1-x}Ge_x$ single photon avalanche detectors (SPAD's) are being grown with x>0.3. The high Ge fraction gives increased absorption for the detection of light of wavelength ≥1.3μm. The high strain sensitivity and non destructive nature of high resolution X-ray diffraction (HRXRD) means that it is a powerful technique for the characterisation of these structures.

In this paper a range of low-pressure vapour phase epitaxial grown SiGe/Si multi-quantum well (MQW) heterostructures have been characterised by HRXRD and modelled using dynamical simulation software. A number of important parameters can be fitted using this technique. For example the technique is especially sensitive to the MQW period, and is able to detect <1% period variation in a 25-period stack, although many samples show much greater variation than this. Deviation from the idealised abrupt well shape can also be modelled. Non-uniformity in both period and well shape across the wafer have been investigated and can be related to growth conditions such as substrate temperature. Thickness measurements from transmission electron microscopy are also used for comparison.

P06.15.003 THE STRUCTURAL MECHANISM OF IMPURITY INFLUENCE ON CRYSTAL GROWTH. V.A. Kuznetsov, T.A. Eremina, T.M. Okhrimenko, N.G. Furmanova, and E.P. Efremova, Institute of Crystallography, Leninsky pr. 59, Moscow 117333, Russia, and N.N. Eremin, Moscow State University, Moscow 117234, Russia.

New aspect of the impurity influence mechanism on crystal growth is considered. The experiments revealed the difference of influence of the M^{3+} and M^{2+} metal ions on growth kinetics and the quality of KDP and KAP crystals, which could not be explained by modern crystal growth theory. The growth promoting effect of M^{3+} ions was typical phenomenon (but at higher supersaturation only), while M^{2+} ions decreased the growth rates deteriorating simultaneously the crystal quality. The computer modelling of the structure of KDP crystals doped by M^{3+} and M^{2+} ionsrevealed the different structures of defect centres formed by these ions: M^{3+} formed isolated centres, while the impurity claster centres were typical for M^{2+} ions. The latter generated more lattice strain.The defect formation energies, structure deformations in defect regions, and generated lattice strain were estimated.The general mechanism of impurity influence taking account of both surface impurity adsorption and the structure deformations is proposed. From the standpoint of this mechanism the difference of the distribution coefficients of M^{3+} and M^{2+} ions, the different influence of them on growth kinetics and quality of crystals were explained.

P07.15.001 ON THE ANOMALOUS PHENOMENA IN CRYSTAL GROWTH OF HIGH QUALITY PINACOIDS OF DIMOLYBDENUM(II,II) TETRACARBOXYLATES. Boris Udovic, Faculty of Chemistry and Chemical Technology, University of Ljubljana, P.O. Box 537, 1001 Ljubljana, Slovenia.

The protonated dimolybdenum(II,II) 3,5-diaminobenzoate tetracarboxylate units $Mo_2(O_2CC_6H_3(NH_3^+)_2)_4$ crystallize in the form of bright pinacoids from concentrated solutions of Cl^-, Br^- or I^- counterions in highly acidic water solutions. The presence of bromide anions offers the easiest way to obtain a solid hydrate compound. On the other hand, the iodide solutions persist in the viscous liquid state also at −22 °C although the stoichiometric ratio of the solvated component remains unchanged. Some observed particularities confirm that the iodide anion is very nearly unhydrated. The electrolytic concentration like temperature effects break up the hydrogen bonds to some extent and water become more close-packed with increase in the percentage of bonds broken. In the highly structured liquid matrix, the larger ions increase the dielectric relaxation effects and generate fault sites, which propagate over large distances. The reduced dielectric saturation causes electrostriction phenomena on shared water molecules of solvent-separated ion-pairs to decrease. Only one proton of water molecule can be directed toward an anion, a lower surface charge density of I^- in comparison to Cl^- reduce the orientation effects on solvent molecules and exert more influence on the effective dielectric constant in its neighbourhood. The hydrogen bonded ionic species $H_3O^+(H_2O)_3$ or $H_9O_4^+$ molecular clusters with rather open structure are indeed broken and the solid phase growth from the acidic solution matrix is hindered also at lower temperatures. The remarkable differences between known negative changes in the self-diffusion activation energy $\Delta E_i^{\neq}$/*Kcal*

mol^{-1} –0.35(NH_4^+), –0.21(Cl^-), –0.39(Br^-) and –0.24(I^-) for water exchange between the first hydration shell and the bulk water at 25 °C give some indications also on the 'structural temperature' effects. The water structure breaking properties of the charged components promote the exceptional solubility of the $Mo_2(O_2CC_6H_3(NH_3^+)_2)_4$ tetracarboxylate.

Crystals of highly protonated 3,5-diaminobenzoic acid in the form of bis(hydrogen chloride) hemihydrate $(H_2N)_2C_6H_3CO_2H\cdot 2HCl\cdot 1/2H_2O$ were grown from a highly electrostricted ionic matrix of water " structure breaking " and " structure making" ions. These were the precursor components in the chaotropic synthesis of in a viscous acceptor microphase of interlattice H_2O and declustered Cl^- counterions. I.R. spectroscopic manifestations of N–H antisymm. and symm. stretch. at 3593 and 3494 cm^{-1} were detected accordingly to the longest C– NH_3^+ bond length 1.471(5) Å in the solved structure of the reference hemihydrate, but appreciably shorter C–N bond lengths 1.444(7) Å and 1.458(6) Å or 1.476(5) Å and 1.475(5) Å are given within equatorial ligands of the $Mo_2(O_2CC_6H_3(NH_2)_2)_4\cdot 8HCl\cdot 16H_2O$ compound with N–H antisymm. and symm. stretch. broadened and shifted to 3356 cm^{-1}. Proton jumps between $-NH_3^+$ and Cl^- in the neighbour water microphase lead to a small amount of double-bond character in the averaged length of C–N bonds, the prospected impulsive +I effects on the aromatic rings promote substantial donic (p–d)π interactions from the equatorial carboxylate groups to the attractive center on the axially tightened dimolybdenum(II,II) core. The shorter equatorial Mo—O_i mean distance 2.109(3) Å in comparison to 2.111(5) Å and 2.119(4) Å in tetrapivalate and tetraacetate compounds confirms the enhanced shielding effect of oxygen atoms on Mo atoms with a slight lengthening of the dimolybdenum quadruply bond 2.1063(8) Å in comparison to 2.088(1) Å, 2.0934(8) Å, 2.096(1) Å bond lengths in tetrapivalate, tetraacetate and tetrabenzoate complexes.

P07.15.003 GROWTH OF DOPED TRIGLYCINE SULFATE CRYSTAL BY SOLUTION METHOD K. Meera, S. Aravazhi and P. Ramasamy [1], [1] Crystal Growth Centre, Anna University, Chennai - 600 025, India

Triglycine Sulfate (TGS) is a ferroelectric material which finds application as room temperature IR detector. This material is synthesised by taking analar grade glycine and sulfuric acid in the molar ratio 3:1. TGS crystals are grown from aqueous solution by slow cooling technique. L-Cystine doped TGS crystals were grown for different mol% of L-Cystine. This dopant is added to the TGS solution in order to bring the crystal to the single domain state. Powder XRD and single crystal XRD has been carried out to identify the lattice parameters and also to demonstrate the crystallinity. Morphological changes has been observed and the results are discussed. Also the presence of dopants has been confirmed by the FTIR analysis taken in the wavelength range 400cm^{-1} to 4000 cm^{-1}. The ICP studies has been carried out to find the composition of sulfur in the crystal. Microhardness has been carried out in the (010) plane. The hardness is found to be decreased when compared with the pure TGS crystal. The results are presented in detail.

P07.15.004 GROWTH AND CHARACTERIZATION OF Cs_XRb_{1-X} $LiSO_4$ SINGLE CRYSTALS BY X-RAY POWDER DIFFRACTION AND RAMAN SPECTROSCOPY MEASUREMENTS. R.J.C. Lima, J.M. Sasaki, P.T.C. Freire, J.M. Filho, F.E.A., Melo, Departamento de Física/Universidade Federal do Ceará, 60455-760, Fortaleza, Ce, Brazil

Good perfect single crystal of mixed $Cs_xRb_{1-x}LiSO_4$ were grown from aqueous solutions by evaporation method at various temperature for nominal Cs concentration within the range of $0 \leq x \leq 1$. This set of crystals were studied by x-ray powder diffraction and Raman spectroscopy. Two distinct phases were observed by x-ray powder diffraction patterns in the range of concentration: monoclinic (for $0.5 > x \geq 0$) and orthorhombic (for $0.6 < x \leq 1$). The volume of the unit cell was determined using Rietveld method (DBWS9411) [1] applied to the x-ray powder diffraction patterns, and this result led to a good indication that the Cs element is getting into the unit cell. By Raman scattering data, we have found an evidence that the rotation mode of the SO_4 ions is more free in $RbLiSO_4$ than in $CsLiSO_4$ crystal. This result is in accordance with both the theoretical results of Katkanant [2] on increasing potential barrier of SO_4 ions as well as the results of Hasebe and Asahi [3] using single crystal x-ray diffraction data for low concentration of Cs. A new crystal was obtained for the nominal concentration of x=0.5 and x=0.6 at 40^{o}C. The attempt to refine the lattice parameter for these crystal with the same space group ($P2_1/c$ – ab2cβ) as proposed by Pietraszko [4] failed. A new symmetry for this crystal was obtained using the DICVOL [5] and ITO [6] programs yielding a good FOM. Both programs gave us an orthorhombic symmetry with lattice parameter: a=15.978Å, b=5.184Å, c=5.042Å. Also, the group theoretical analysis and the Raman results were used to aid the identification of the point group symmetry C_{2v}^4(Pma2) of the new material.

This work is supported by Brazilian Agencies CNPq, FINEP and FUNCAP/FCPC/UFC

P07.15.007 PRECRYSTALLIZATION CLUSTERS (QUATARONS) AND CRYSTAL GROWTH. A.M.Askhabov, Institute of Geology of the Komi Science Centre, Uralian Division of RAS, Syktyvkar, Russia.

There are two alternative concepts developing in the theory of crystal growth. According to the first, the building blocks for crystals are atoms (ions) or molecules (atomic growth). The second concept suggests that crystals grow by joining ready crystalline blocks (microblock growth). We have put forward a new model of crystal growth suggesting that peculiar atom or molecular associations (clusters of a transient "hidden" phase) arise in crystal-forming media. These clusters were named "quatarons" according to the characteristic ball-like shape ("quatara" means "a ball" in the native tongue of the author). Quatarons have a number of properties which distinguish them from ordinary clusters and crystal nuclei described in the classical theory of crystal growth. In particular, quatarons have the limiting size. The limiting size quatarons act as potential crystallisation centres. They display neither crystalline structure nor translational symmetry. The quataron mechanism of crystal growth is extremely simple. A quataron adsorbed on crystal surface grows in size at the expense of atoms from the crystal lattice. A situation when one part of atoms is arranged into a lattice and the other is in a dynamic state cannot long exist in such "effective" quatarons. Crystallisation of quatarons becomes unavoidable and occurs at far smaller supersaturations than the limiting one. Thus, quatarons resolve the fundamental problem of the origin of stages during crystal growth by layers and account for continuous crystal growth in weakly supersaturated media and in the absence of dislocations. The only exception from the rule is precipitation of rigid fullerene-like quatarons with fully closed bonds on a base. This case accounts for formation of solid noncrystalline materials - quatarites.

The work was supported by RFFI, grant No.99-05-64883.

P07.15.010 GROWTH AND CHARACTERISATION OF BISMUTH THIO CHLORIDE. D. Arivuoli and G. Kanchana Department of Physics, Anna University, Chennai-25, India.

Bismuth sulfo chloride belongs to SbSI type compounds showing interesting physical properties like ferroelectric and semiconducting. Single crystals of bismuth thiochloride were grown from sodium meta silicate gel at room temperature. Bismuth chloride and thiourea were used as the outer and inner reactants with various concentrations. The crystals were also grown in acidic medium at room temperature. The gel grown crystals exhibited interesting dendritic, platelet and hopper morphology depending upon the concentration of the inner and outer reactant. The dendrites grew within days when the inner and outer concentration exceeded 2M. The arms of the dendrites were not well pronounced with the primary arm orienting along (001) direction and in most of the dendrites secondary arms were observed only on one side of the primary arm. Some of the platelets showed dendritic patterns at the edges of the faces. Larger size single crystals of 16mm x 12mm x 8mm were obtained for the gel density of 1.05 with 1M bismuth chloride and thiourea. On increasing the concentration of the bismuth chloride, more crystals were found to be twinned. SEM pictures of hopper crystals showed step like structures and the hopper was found to be more pronounced along [100] direction than the other faces. Some of the solution grown crystals showed twinning. Thermal characteristics were determined using TGA and DSC. EDAX analysis showed the presence of stoichiometric composition of the elements. FTIR and X-ray analysis were also carried out to identify the compounds.

P07.15.011 GROWTH OF CUSO4×5H2O CRYSTALS IN SLIGHTLY CROSS-LINKED POLY(VINYL-CAPROLACTAM) GELS. Nasimova I.R., Evlanova N.F., Makhaeva E.E., Khokhlov A.R. Physics Department, Moscow State University, Moscow, 117234, Russia.

The present work is devoted to the study of the application of slightly cross-linked poly(vinylcaprolactam) (PVCa) gels as a medium for growth of CuSO4×5H2O crystals. PVCa is known to be a good absorbent for different substances. The efficient absorption of CuSO4 by the PVCa gels from aqueous solution was observed. The absorption was being accompanied with the gel shrinking. The further immersion of the gels containing CuSO4 into ethanol leads to the growth of CuSO4 crystals inside the PVCa gel. The growth of crystals was a result of the saturation of CuSO4 solution inside the gel due to diffusion of ethanol molecules into the gel and back diffusion of water molecules into external solution. The experiments were made for the gels with different polymer content (4% and 7% PVCa). In the both cases the growth of dendrite crystals was observed. It was shown that the crystals habit depends on the density of polymer network. A pattern of crystals growth in the gel differs from that in solution with the same water/ethanol ratio. This fact is explained by the absence of convection flows in gels. Therefore the results obtained show that slightly cross-linked PVCa gel is promising as a medium for growth of crystals.

P07.15.012 SINGLE CRYSTAL GROWTH OF POLYMORPHIC ER2SI2O7 CERAMICS. Asghari Maqsood Thermal Physics Laboratory, Department of Physics, Quaid-i-Azam University, Islamabad, Pakistan.

Optically clear single crystals of the polymorphic Er2Si2O7 have been produced by the flux method. X-ray diffraction studies show that Er2Si2O7 exists in three modifications - a triclinic low temperature phase(type B), a monoclinic modification (type C) and a high temperature monoclinic modification (type D). Starting compositions and experimental conditions for crystal growth are discussed at length. The lattice constants along with the space groups are also reported.

P07.15.013 MORPHOLOGY OF CARBON DIOXIDE CLATHRATE HYDRATE CRYSTAL. Tomoko Ikeda and Shinji Mae, Department of Applied Physics, Faculty of Engineering, Hokkaido University, N13 W8, Sapporo 060-8628, Japan.

In-situ study on crystal growth of carbon dioxide clathrate hydrate in aqueous solutions has been performed. Using a high-pressure cell on an optical microscope stage, we observed the formation and growth processes of CO_2 clathrate hydrate in temperature range of 275-283 K, and pressure range of 3.7-4.5 MPa. From observation of the growth rate and morphology of the crystal, we found that the orientation of the surface of the crystal as it growth is dominated by supercooled temperature DT. The crystal with the <110> axis perpendicular to the surface grows at DT < 3.5 K. We measured Raman spectra of the crystal in order to investigate the effect of motion of the guest molecules (i.e., CO_2) on the orientation of the crystal growth. It was found that the CO_2 molecule inside the tetrakaidecahedral cage rotates about the symmetry axis of the cage as proposed by the previous studies [1]. Using neutron powder diffraction, Ikeda et al.[2] showed that the surrounding hydrogen atoms are temporally attracted and released by the oxygen atoms of the rotating CO_2. Thus, the interaction between the CO_2 molecule and the hydrogen atoms of the lattice is thought to be strong. We conclude that the crystal growth of clathrate hydrate is influenced by the anisotropic rotation of the guest molecules.

P07.15.014 CONTROL OF POLYMORPHIC CRYSTALLIZATIONS BASED ON AN ENERGY-TEMPERATURE DIAGRAM. Joseph G. Stowell, Xiaorong He, Ulrich J. Griesser, and Stephen R. Byrn. Department of Industrial and Physical Pharmacy, Purdue University, West Lafayette, IN USA 47907-1336.

Four polychromic forms of 5-methyl-2-[(4-methyl-2-nitrophenyl)amino]-3-cyanothiophenecarbonitrile (4'-Me) were studied in order to develop laboratory-scale crystallization conditions that would control the polymorph obtained. The polymorphs were characterized by DCS, XRPD, FTIR, and hot-stage microscopy, as well as solubility and slurry-convertions studies. Based on these results, an energy-temperature diagram was constructed. Batch crystallizations of 4'-Me were performed at various supersaturations and various cooling rates in anhydrous ethanol.

The temperatures at which the four energetically similar, enantiotrop-ically related polymorphs [red (R), dark red (DR), light red (LR), and orange (O)] interconvert were predicted by the solubility and slurry-conversion studies. The results followed the density rule. The thermodynamically most stable form above 60 °C is R. The O, LR, and DR polymorphs transform to R upon heating to 100 °C in anhydrous ethanol. At 25–60 °C, O is the thermodynamically most stable form. Below –30 °C, LR is the themo-dynamically most stable form. Throughout the entire temperature range studied, DR is metastable.

Batch crystallization above 60 °C gave R preferentially without seeding. Similarly, LR was obtained at temperatures between 10 °C and 50 °C without seeding. Seeding supersaturated solutions with DR crystals (0.5% w/w) afforded DR when the crystals were harvested immediately after

crystallization. Prolonged slurrying of R, LR, or DR at temperatures between 25 °C and 60 °C yield O. Thus, the formation of a particular polymorph can be predicted by understanding the complex thermodynamic relationships between the four polychromic polymorphs of 4'-Me.

P07.15.015 STUDY OF SURFACE FEATURES AND POLYTYPISM IN DENTRITIC SINGLE CRYSTALS OF CdI_2. Binay Kumar & G. C. Trigunayat, Department of Physics & Astrophysics, University of Delhi, Delhi-110007.

Dendritic single crystals of cadmium iodide are grown by vapour method. The basal surfaces of the as-grown crystals are examined by optical and electron microscopy and then they are etched by water vapour for different time intervals and at different temperatures. The etch pits are examined by microscopic methods. Next, CdI_2 crystals are grown with doping of isostructural compound PbI_2 and subsequently subjected to similar studies. The crystal polytypes are identified by x-ray diffraction for both doped and undoped crystals. The x-ray photographs are found to display arcing and streaking of the reflections, too. A wide variety of growth features are observed on the crystal surfaces, viz. growth steps and their bunching, overgrowths, slip lines and slip bands, apart from usual dendritic features. The etching produces hexagonal pits in the case of undoped crystals while both hexagonal and triangular pits are observed in the case of doped crystals. The density, shape and size of etch pits differ for two cases. Regarding polytype composition, the undoped crystals are mostly found to consist of the common four layered hexagonal polytype, 4H. On the other hand, the doped crystals are found to contain twelve layered rhombohedral polytype, 12R, too. The occurrence of polytypes, arcing and streaking of the reflections are explained on the basis of defects created during the growth of crystals. The bearing of these defects on the surface features are also analysed.

P07.15.016 POLYMORPHISM AND NONLINEAR OPTICAL ACTIVITY IN SODIUM P-NITROPHENOLATE. S. Brahadeeswaran and H.L. Bhat, Department of Physics, Indian Institute of Science, Bangalore- 560012, INDIA.

In recent years extensive research has been done on polymorphism in organic nonlinear optical (NLO) materials. Prior knowledge of polymorphism is essential for crystal growers, particularly working in the field of organic NLO materials, since polymorphs may exist due to varying solvents, changing crystallisation conditions, etc. In this paper we report our results on the studies performed on sodium p-nitrophenolate (NPNa). Two solvents, viz. methanol and water were used to grow the crystals of NPNa. While the methanol solution gave transparent and stable crystals of NPNa dihydrate [1] the water solution gave two polymorphs which were very distinguishable from their colours (yellowish and reddish brown). One of the water grown forms (yellowish) lost its transparency on exposure to atmosphere whereas the other form (reddish brown) was quite stable. These two forms were also distinguishable by other characterisation studies such as thermal analyses, powder x-ray diffraction (XRD) and powder SHG employing Kurtz technique. Subsequently, we have solved the structures of these two forms by the single crystal XRD technique. Of these two forms, the yellowish crystal was identified as NPNa tetrahydrate and the reddish brown as NPNa monohydrate. While the former exhibited a centrosymmetric ($P2_1/C$) space group with lattice parameters a = 11.944 Å, b = 6.968 Å, c = 26.002 Å, β = 101.36° and Z = 8, the latter had a noncentrosymmetric (C2) structure with lattice parameters a = 21.193 Å, b = 3.669 Å, c = 10.358 Å, β = 117.22° and Z = 4, and exhibited NLO activity. The coordination and hydrogen bondings of these structures will be discussed in detail and compared with that of NPNa dihydrate.

P07.15.017 THREE DIMENSIONAL INSTABILITY AND TEMPERATURE OSCILLATIONS, INDUCED BY GRAVITY-DRIVEN AND ROTATIONAL FLOWS IN CZOCHRALSKI SYSTEM. MICROGRAVITY ALTERNATIVES. V.I. Polezhaev ,V.G. Kosushkin, S.A.Nikitin, N.V.Nikitin, Institut Of Problems In Mechanics Ras, Vernadskogo Pr. ,101, Moscow 117526, Russia

Temperature oscillations of gravity-driven fluid flow with rotation and nonlinear interaction in Czochralski system are studied using direct computer simulation and stability analysis on the basis of unsteady Navier- Stokes equations (Boussinesque approach) for axisymmetry and three- dimensional approaches. A focus of the paper is concentrated on the results of parametrical analysis of nonlinear coupling fluid flows using new mathematical modelling technique, comparison with experimental data and analysis of the microgravity alternatives to avoid instability and temperature oscilations in the melt.

Analysis with the use of the parameters of international benchmark (the case with prescribed temperatures on the seed and crucible wall, and isolation of the crucible bottom and linear temperature distribution on the melt surface) are done in a first part of the paper. Oscillations nature and damping of oscillations using adiabatic melt surface is discussed.

Second part of the paper is related to the parametrical analysis of ground-based regime of GaAs crystal growth with counterrotation. Oscillation's mechanism for the case of zero rotation and for the coupling nonlinear case are presented in axisymmetrical and three dimensial approaches. Two types of gravity - driven convection - Rayleigh - Bernard type due to cooling above of the disk and side heating of crucible are shown. Validation of computational solutions is discussed using comparison with experimental data of temperature oscillation.

Computer simulation and video visualization of the unsteady convective processes are done on the basis of special version of PC-based system "COMGA".

The work is supported by the joint NASA-RSA program (project N TM-11)

P07.15.018 VAPOR TRANSPORT GROWTH OF ORGANIC CRYSTALS: MORPHOLOGY VERSUS GRAVITY. M. Ittu Zugrav, Consortium for Materials Development in Space, University of Alabama in Huntsville, Huntsville, Alabama 35899, USA, F. C. Wessling, Department of Mechanical and Aerospace Engineering, University of Alabama in Huntsville, Huntsville, Alabama 35899, USA and W. E. Carswell, Alliance for Microgravity Materials Science and Applications, University of Alabama in Huntsville, Huntsville, Alabama 35899, USA.

Effusive ampoule physical vapor transport (EAPVT) has been used to grow crystals of N,N–dimethyl–p–(2,2 dicyanovinyl) aniline (DCVA). A series of multi-parameter experiments have been conducted both in microgravity on board the Space Shuttle Endeavour and in the laboratory as ground controls using the Moderate Temperature Facility (MTF). MTF uses very little power for materials processing and is capable of operating on several different microgravity experiment carriers, including the Space Transportation System (STS) and the International Space Station (ISS). Special design considerations allow the facility to operate at a 130°C interior temperature with a power consumption of 2.4 W in a 20°C environment. This thermal efficiency is achieved by minimizing radiative, conductive, and convective heat losses. The facility has flown on four Space missions so far and is planned to fly on the ISS. The EAPVT hardware consists of six

ovens and each oven contains two separate growth cells which allow the independent processing of two samples simultaneously. During Earth-based processing by EAPVT, DCVA forms exclusively bulk crystals. The space grown samples, however, showed a completely different growth form than did the ground samples. Instead of the bulk crystals, all of the space samples were thin film deposits. Oriented and ordered DCVA thin films were reproducibly grown in microgravity during two flights (STS-59; CONCAP IV-2 and STS-69; CONCAP IV-3). The experiments have demonstrated that the morphology of DCVA crystals is highly dependent upon gravity. The premise is that the bonds are weak in nature (Van der Waals) and are significantly impacted by gravity. Ground-based research have intensified to determine the validity of this theory, that is, if the impact of gravitational forces can be overcome by other process parameters. This result will add considerable insight into the "Van der Waals" nature of the epitaxial growth process for DCVA and will have influential impact in the field. To date, the STS-59 and STS-69 results obtained for the growth of DCVA in microgravity, have not been duplicated in a normal gravity environment. The results are discussed with reference to the growth parameters.

P07.15.019 MACROMOLECULAR CRYSTAL GROWTH EXPERIMENTS IN MICROGRAVITY. Karen Moore, Marianna Long and Lawrence DeLucas, Center for Macromolecular Crystallography, University of Alabama at Birmingham, 288 MCLM, 1918 University Boulevard, UAB Station, Birmingham, Alabama, USA.

Vapor diffusion crystallization experiments have been conducted in a microgravity environment since 1984, using a variety of launch vehicles including the US Space Shuttle and the MIR Station. Results from these experiments have shown that minimization of gravity-induced convective flows can be beneficial for macromolecular crystal growth. Crystals grown in microgravity frequently have improved optical and crystallographic quality relative to those grown in conventional 1-g experiments [1-3].

Vapor diffusion and temperature-induced crystallization experiments have been conducted by the Center for Macromolecular Crystallography aboard thirty seven missions of the US Space Shuttle. These experiments included an extensive selection of macromolecular compounds flown in collaboration with crystallographers throughout the world. Experiments conducted on three recent Shuttle flights, STS-94, STS-86 and STS-95, have produced outstanding results. Twenty eight different macromolecular compounds were involved in the vapor diffusion experiments conducted on STS-94 and STS-95, and the temperature-induced crystallization experiments conducted on STS-85 involved several formulations of the same protein.

A review of the development of space-flight hardware for vapor diffusion and temperature-induced crystallization experiments will be presented along with a discussion of experimental techniques developed for the microgravity environment. An overview of microgravity experiments conducted on STS the recent shuttle missions will be presented and the results of the crystallographic studies of crystals grown in these will discussed relative to results from earth-grown crystals.

P07.15.024 PACKING PATTERN AND CONFORMATION OF LOW-MELTING-POINT COMPOUNDS IN CRYSTALLINE STATE. Y. Yokoyama, Synthesis Technology Laboratory, Chugai Pharmaceutical Co., Ltd., Ukima, Kita-ku, Tokyo and Y. Ohashi, Department of Chemistry, Tokyo Institute of Technology, Ookayama, Meguro-ku, Tokyo

The crystal structure of the compounds that are liquid at room temperature and atmospheric pressure were studied with in situ crystallization technique and X-ray diffraction analysis. The systematic crystal structure analyses of the simple molecules revealed some intermolecular interactions in the crystalline state. Some of these interactions were responsible to the preference conformations that the conformation in the crystalline state is not in agreement of the stable one in the gaseous state or on the basis of the ab initio molecular orbital calculation.

The compounds, which have the CN group, tend to form the hydrogen bonds to H2C-CN. This tendency is emphasized in the compounds S-CN, thiocyanate ester. Therefore the substitution of the methyl group in ethylthiocyanate by chloro leads to isomorphism. In the compounds, which have C-O or C-S bonds, the dimer-like pairs through the C-H...O or C-H...S hydrogen bonds are observed and form the four-, six- and eight-membered ring. Two molecules are coupled by two antiparallel C-H...O or C-H...S hydrogen bonds to form a four-membered ring. Such a dimer-like pair may be strengthened by the intermolecular interaction between the C-O or C-S bond moments in the four-membered ring. The six-membered ring may be related to the stabilization of the gauche conformation in the crystalline state, when the trans conformation is preferred in the gaseous state or stable on the basis of the ab initio molecular orbital calculation. The intermolecular interaction such as the anomeric effect in the six-membered ring leads to the gauche conformation. In addition, the CN...halogen interaction seems to stabilize the gauche conformation.

P07.15.025 DEVELOPMENT OF A CRYSTALL-ISATION SCREEN FOR ORGANIC COMPOUNDS. C. Keats, K. Prout, D. Watkin, Chemical Crystallography Laboratory, 9 Parks Road, Oxford, OX1 3PD, UK and G. Tranter, Glaxowellcome Medicines Research Centre, Gunnelswood Road, Stevenage, Hertfordshire, SG1 2NY, UK.

Molecular structure determination by X-ray diffraction has the potential to become a routine analytical tool. Single crystal analysis has been revolutionised by CCD diffractometers, which can collect analytical quality data in a few hours, and powder diffraction is gaining importance through new methods of ab-initio structure solution. Eventually, both techniques will be limited by the availability of suitable crystalline material. For single crystal work, a sample size of a few tenths of a mm is adequate. Well-crystallised material is needed even for powder diffraction. It has been shown that usually sample quality rather than instrument capability is the factor limiting the diffraction data resolution.

The growth of crystals for either technique is not well characterised, and though some systems have been intensely studied, there are no generally applicable rules or guidelines. Solution crystallisation is the easiest technique to implement into a screening process; the modifying factors are the properties of the solvent of evaporation and the interaction of the crystallisation molecule with the solvent molecules. Cluster analysis of many organic solvent properties, such as dielectric constant, hydrogen bonding and dipole moment has produced a subset of 60 solvents, which cover the widest range of properties and thus comprise a useful screen. A search of the CSD revealed very few small organic molecules that have more than 3 reported polymorphs. A group of 10 compounds exhibiting polymorphism have been selected that are or have been of pharmaceutical interest, and are

being systematically crystallised using the screening method. Analysis of the polymorphs is done by single crystal X-ray diffraction.

Information generated from the screen can be used to assess which conditions produce good quality crystals for a variety of systems and which polymorphs or solvates can be formed. Utilisation of information concerning the behaviour of a compound could dramatically limit the screen.

P09.15.001 STRUCTURAL PECULIARITIES OF $LIGAO_2$. G.M.Kuz'micheva, M.V.Lomonosov State Academy of Fine Chemical Technology, Vernadsky prosp. 86, Moscow 117571, A.V. Gaister and E.V. Zharikov, D. I. Mendeleev University of Chemical Technology, Miusskaya sq. 9, Moscow 125047, and V. B. Rybakov, M. V. Lomonosov State University, Vorobyevy gory, Moscow 119899, Russia.

The enantiomorphism is an ability of crystal to exist in two mirror equal forms ("right" and "left"). There is not symmetry centre, symmetry plane and inversion axis in the point symmetry of these crystals (1, 2, 3, 4, 6, 222, 32, 422, 622, 23, 432). Earlier it was theoretically suggested to exhibit enantiomorphism for point groups -4, -42m, m, mm2. Crystal structure of $LiGaO_2$ (space group $Pna2_1$, point group mm2) is derivative of wurzite structure. Li^{1+} and Ga^{3+}- ions occupy tetrahedrally-coordinated sites, shared with each other by oxygen ions. An analysis of experimental x-ray results indicated that the "milky" single crystal $LiGaO_2$ (LGII) is twinned one, that consists of the crystals with corrected (C) and inverted (I) structures in the ratio 60:40(%), whereas the "transparent" single crystals $LiGaO_2$ (LGI) is completely C-type. Samples LG(I) (C) and LG(II) (C) differ from each other by lithium contents (in LG(II) less than in LG(I)) and value of Z-position (in LG(II) much less than in LG(I)) and the longest interatomic distance (cation-anion) associated with it. The observed behavior of these parameters probably can be related with tendency toward cation transition from present tetrahedral sites (C-structure) into another ones (I-structure). According to results of structure refinement of $LiGaO_2$:Li,V (LG(V)), $LiGaO_2$:Li,Al,Cr (LG(Al,Cr)) and $LiGaO_2$:Li,Sc,Cr (LG(Sc,Cr)) obtained by the Czochralski technique, I and C structures realize for LG(V) ($r_v<r_{Ga}$), LG(Al,Cr) ($r_{Al}<r_{Ga}$) and LG(Sc,Cr) ($r_{Sc}>r_{Ga}$) respectively. It was concluded that the changes in the structure depend on the radius (r,A) of the cation and the kind of point defects.

P09.15.002 ELECTRIC FIELD AS INSTRUMENT FOR OBTAINING AS-GROWN PERIODIC POLED LITHIUM NIOBATE CRYSTALS. E.P.Kokanyan, Institute for Physical Research National Academy of Sciences of Armenia, Ashtarak, Armenia.

The increasing interest in ferroelectric crystals with a periodic poled domain structure requires search of new technological methods of their obtaining.

In the present work lithium niobate crystals with a periodic poled domain structure (PPLN) have been grown by the Czochralski technique using an electric field applied to the crystal-melt system during the growth process. The change of the polarity of applied electric field and the density of electric current passing through the crystal-melt system lead to change of effective distribution coefficient of impurities and main components of the system caused by electrochemical processes arising in the crystal melt-system [1]. These instantaneous changes along the growth direction give a possibility of PPLN crystals with controlled period growing. The PPLN structure with a period of 3-60mkm obtained in this way was studied using selective chemical etching and electron microscope.

P09.15.003 PERIODICALLY POLED CZOCHRALSKI GROWN LITHIUM NIOBATE SINGLE CRYSTAL. T.O.Chaplina, I.I.Naumova, N.F.Evlanova, S.A.Blokhin, S.V.Lavrishchev[1], Physical Dep. Moscow State University, Moscow 119899, [1]General Physical Institute RAS, Moscow 117924, Russia

Bulk periodically poled $LiNbO_3$ single crystal is a promising material for nonlinear optical devices using quasi-phase-matching (QPM). The domain structure of crystals and the distribution of impurities depend on the crystallographic orientation of seed. Earlier we investigated periodically poled Nd:Mg:$LiNbO_3$ crystals grown by the Czochralski method along the normal to the $(01\bar{1}2)$ face[1,2]. The face on the growth front favored of formation of flat and regularly spaced ferroelectric domain boundaries. Using selective chemical etching, scanning electron microscope (SEM) and wave dispersive X-ray microanalysis we showed that the ferroelectric domain walls coincide with the maxima and minima Nd-impurity modulation[2]. Along this growth direction the concentration of Nd and Mg impurities are in antiphase.

Y: $LiNbO_3$ and Y:Mg: $LiNbO_3$ crystals were grown by the Czochralski method along $[2\bar{1}\bar{1}0]$ (X-axis). This growth direction is a good practice for using the highest nonlinear coefficient d_{33} in the QPM nonlinear-optical conversions. The regular domain structure with a period 7-60 mkm was studied with selective chemical etching and metallographic microscope. In a system of the regular domains corresponding to the usual rotation striations we observed additional domains associated with the concetration phenomena on the growth front.

The modulation of Y- and Mg- impurities along the growth directions was measured with wave dispersive X-ray microanalysis in the SEM. In the Nd:Mg:$LiNbO_3$ crystal grown along X-axis we showed earlier [1] that Nd-modulation in the periodically poled region had larger gradient of the concentration than in the nearest single domain region of this crystal In the present work we discuss the peculiarities of the domain structure and impurity concentration distribution associated with the used crystallographic growth direction.

P09.15.004 GROWTH AND OPTICAL PROPERTIES OF Nd-DOPED $Bi_4Ge_3O_{12}$ SINGLE CRYSTALS. C.M. Whang, Dept. of Ceramic Engineering, Inha University, Inchon 402-751, Republic of Korea and I.K. Bae, Division of Geology, Korean Institute of Geology, Mining and Materials, Daejon 305-350, Republic of Korea.

Single crystals of $Bi_4Ge_3O_{12}$ (BGO) doped with rare earth elements such as Nd is of practical interest because of its potential use as laser materials. The Nd-doped BGO has a broader absorption band at about 800nm compared with Nd:YAG, so it can absorb the pump light of a diode laser more efficiently.

In this work, the Nd-doped BGO crystals were grown in the auto-diameter control system equipped with frequency weighing sensor by the Czochralski method. The Nd doping level was varied from 1 to 3 at.%. The optimum growth conditions, under O_2 atmosphere, of the single crystals were as follows: Pulling rate; 1mm/hr: rotation rate; 34rpm: temperature gradient; 100 deg/cm. Transparent and light purple colored crystals grown have typical size of approximately 25mm in diameter and 50mm

in length. The preferred growth direction was confirmed to be <110>. The dislocation density was estimated to be $10^3/cm^2$.

Growth parameter, morphology and chemical composition of the grown single crystal were studied. Although Nd^{3+} needs no charge compensation as it substitutes for Bi^{3+} ions, its ionic radius is little larger than that of Bi^{3+}. The crystallochemical behavior of the Bi^{3+} ion is more closely related to the larger trivalent rare earth ions such as Nd^{3+} than to the smaller ones, just as Kaminskii [1] suggested. The effective distribution coefficient $K_{eff}(X_{crystal}/X_{melt})$ of Nd^{+3} ion obtained by chemical analysis was 0.93 which is in good agreement with the result of Kaminskii. Distribution of Nd ion concentration of Nd-doped BGO was investigated by PIXE analyzer and found to be uniform. Also, we report optical properties of the crystals obtained by IR, Raman and Luminescence spectra.

P09.15.005 X-RAY IMAGING OF ALLOY SOLIDIFICATION PROCESSES. R. H. Mathiesen[a], L. Arnberg[a], F. Mo[a], T. Weitkamp[b] & A. Snigirev[b]. [a] Norges Teknisk Naturvitenskapelige Universitet, NTNU, Trondheim, Norway. [b] ESRF, Grenoble, France.

In situ experimental studies of dendritic alloy solidification processes have been carried out for the first time. $Sn_{0.9}Pb_{0.1}$ enclosed in a glass cuvette of dimensions $30\times20\times0.15mm^3$ was melted and introduced rapidly into a directional temperature gradient field varied in the range $dT/dx \in$ [1,20 K/mm]. 23.89 keV monochromatic X-rays were used to make images of a 1×1 mm^2 cross section with resolution down to 2 μm during the solidification. Exposure times down to 0.1 s with a read-out time of the same magnitude was obtained using a Fast REad-Out Low Noise (FRELON I) CCD camera giving a 0.2 s time-elapse between consecutive frames. This time and spatial resolution was adequate to provide quantitative and qualitative information for dendritic growth rates as high as 2.5 mm/s. The dendritic growth of the $Sn_{0.9}Pb_{0.1}$ alloys showed the predicted relationship between dendritic tip radius, temperature gradient and growth rate. A balance between two effects was decisive for the growth process: Under-cooling of the melt at the solidification front with heat conducted through a crystalline solid and an effective diffusion field for the alloying elements at the solidus/liquidus interface. The latter effect has not been observed previously.

P09.15.006 GAS-BUBBLE ENTRAPMENT IN TeO_2 SINGLE CRYSTALS. R.M.Grechishkin, A.I.Kolesnikov and S.S.Soshin, Tver State University, Zheliabova Str., 33, 170000 Tver, Russia

Gas bubbles are inadmissible defects which restrict the use of paratellurite (TeO_2) single crystals in acoustooptical devices [1]. In the present work we study the gas bubble distribution by size and location inside the Czochralsky-grown paratellurite crystals by optical methods including polarized anisotropic dark field observation (PADO). Large single crystals produced under varying conditions of growth were examined. The bubbles were found to locate mainly in the central parts of the crystal corresponding to the crystallization front convex downwards. The measured bubble radii fall into the range of 1.5 to 25 μm and exhibit either one maximum at 8-10 μm or (unexpectedly) two maxima at 3-4 and 14-18 μm, respectively. In the latter case bubble radii in the range of 6-12 μm are completely absent.

To explain this phenomenon and to find the conditions for bubble-free Czochralsky growth of paratellurite we have calculated the bubble diffusion growth rates and the forces on the bubble near the ctystallization front. It was found that in the case of high axial temperature gradients in the melt and low pulling rates a complete push off of the bubbles is possible by the following mechanism. Bubbles having sizes below a critical value are dissolved in itself in the melt. The bubbles with a radius slightly above the critical value grow rapidly and are dragged downwards by the thermocapillar forces and so they are not captured by the growing crystal. These bubbles, when they become large enough during further growth, tend to float again to the crystallization front under the action of Archimedean force, but are carried out from under the crystal to the free surface of the melt by the horizontal flux component forced by the crystal rotation.

The results of the study were used in the refinement of the technology of producing bubble-free paratellurite single crystals of optical quality with a diameter up to 80 mm.

P09.15.007 COMPOSITIONAL DEISTRIBUTION AND DEFECTS OF HGCDTE CRYSTAL GROWING IN MAGENTIC FIELD. R. D. Xia [1], M. Lan, S. Ye, Y. Mei, S. Zhou [2], [1] Electrical and Electronic Engineering, University of Nottingham, University Park, Nottingham, NG7 2RD, UK, [2] Harbin Institute of Technology, Box328, 150001, P. R. China

The Cadmium Mercury Telluride (Hg1-xCdxTe) single crystal with homogeneous composition in large area is a potential material for infrared focal plane detector. However, the composition uniformity demanded for device fabrication can not be satisfied due to the large margin existing between solid and liquid lines on its phase diagram [1]. In this work, the compositional distribution and defects in Hg1-xCdxTe grown by means of Bridgman method are investigated. The result shows that the crystal quality can be improved by the suppression of magnetise field on convection, mass transportation and heat conduction.

The results of composition study indicate that the transverse magnetic field applied during the growth of Hg1-xCdxTe crystal can convert the axisymmetrical radial compositional distribution into eccentric distribution, which lead to a significant decrease on the deviation of the radial compositional distribution. The corrosion analyses on sub-boundaries and dislocations show that the average density of dislocation exhibits an axisymmetrical distribution with a maximum density at centre in the samples without magnetic field applied but a homogeneous distribution in those with magnetic field applied.

P09.15.008 GROWTH OF HIGH MOBILITY INSB CRYSTALS BY VERTICAL BRIDGMAN METHOD. Premila Mohan [1], N. Senguttuvan [2], S. Moorthy Babu [1] and P. Ramasamy [1], [1] Crystal Growth Centre, Anna University, Chennai - 600 025, India, [2] Shonan Institute of Technology, Fujisawa, Japan

Indium antimonide (InSb) is a technologically important III-V semiconducting material which finds application as a mid-wave infrared detector and infrared filter. Its relatively low melting point, direct small energy gap and large carrier mobility makes it suitable for such devices. The responsivity and detectivity of the detectors are directly related to the internal parameters of the semiconductor including electron and hole concentrations and mobilities. In the present work InSb crystals were grown from 6N pure In and 6N pure Sb by vertical Bridgman technique. An indigenously developed vertical Bridgman setup

consisting of a two zone resistive heating furnace controlled by two separate Eurotherm controllers and an electronic ampoule lowering assembly was used for the purpose. Series of experiments were carried out to optimise the growth conditions such as the axial temperature gradient and ampoule lowering rate. The ampoule geometry was also found to play a dominant role in the quality of the crystals. The grown crystals were characterised by various techniques such as powder x-ray diffraction, energy dispersive X-ray analysis and electron probe microanalysis. The electrical properties of the grown crystals were studied using the Vander Pauw technique. The variation of the carrier concentration along the length of the crystal was also studied. The mobility of the crystal was found to be nearly 60000cm^2/Vs.

P09.15.009 GROWTH RATE AND MORPHOLOGY OF WATER-SOLUBLE IONIC CRYSTALS: MODELING WITH COULOMB-ONLY POTENTIALS. L.J. Soltzberg, G.S. Defoe, Z. Khan, E. Madden, and D.L. Marr, Department of Chemistry, Simmons College, Boston, MA 02115.

We have recorded the crystal morphologies of ten water-soluble univalent ionic compounds grown over a wide range of supersaturation. These crystals represent a variety of space groups and structure types, including two with extensive hydrogen bonding. Growth rates range from very slow growth giving mature, "late-growth" crystals; through faster growth characteristic of the early stages of crystallization, giving "early-growth" morphology; to very rapid crystallization producing dendritic morphology. We have modelled the morphologies of each of these crystals using attachment energies computed with the MARVIN code [1]. The predicted morphologies generally give very good agreement with observed late-growth morphologies. Further, the early-growth morphologies can be modeled by artificially reducing the relative attachment energies of one or, occasionally, two growth directions as shown below. Directions of needle crystal growth marking the onset of dendritic crystallization correspond to high attachment energies and correspondingly rapid growth. It is noteworthy that we can model these morphologies using only Coulomb potentials, presumably because electrostatic interaction dominates the lattice energy in these ionic systems.

P09.15.010 NUMERICAL SIMULATION AND OBSERVATION OF THE GROWTH DIFFERENCE ALONG THE POLAR AXIS OF LiB_3O_5. J. H. Jung, H. M. Park* and S. J. Chung, School of Materials Science and Engineering, Seoul National University, Seoul 151-742, Korea. *Materials Evaluation Center, KRISS, Taejon 305-600, Korea.

The single crystals of lithium triborate (abbr.; LBO) were grown by top-seeded solution growth using <010> seed normal to the polar axis and the difference of growth rate between the opposite ends of polar direction was observed during the growth process.

In the beginning stage of cooling range down to 3º during the growth process, the growth rate in one of the polar direction is much higher than that of in the opposite direction. After cooling down to 3º the difference of growth rate is reduced gradually.

The growth rates and the lengths of grown crystal along the polar axis were numerically simulated with some known data related to LBO crystal and the solution. The assumptions that the spontaneous polarization of LBO crystal form an electric field only near the interface between the crystal and the conductive solution and this spontaneous polarization due to the asymmetric arrangement of structural building units results in the repulsive or attractive forces to the charged growth units and the difference of mass transfer between both ends of the polar axis were introduced in the simulation.

The calculated results were compared with the experimental observations and they fit well together. The polar direction of the grown crystals were detected by the observations of etch pits and the measurements of pyroelectric coefficient which was even much smaller then that of the other pyroelectric crystals.

P09.15.011 IDENTIFICATION OF CLEAVAGE PLANES IN SALTS USING MOLECULAR MODELLING. J.C. Osborn and P. York, Drug Delivery Group, School of Pharmacy, University of Bradford, Bradford BD7 1DP, UK, and R.C. Rowe and R.J. Roberts, Zeneca Pharmaceuticals, Alderley Park, Macclesfield Cheshire SK10 2NA, UK.

The cleavage properties of crystalline pharmaceutical materials are important in the processing of tablets. Previously molecular modelling has been employed to predict morphology and slip planes in molecular materials. However many drugs are formulated as salts so that an extension of these techniques to molecular salts is required.

The surface attachment energy which is calculated in models of crystal growth may be utilised to identify cleavage planes by postulating that the most weakly attached plane has the least resistance to slip. Attachment energy calculations for salts require allowance for the long-range electrostatic interactions. Calculations have been performed using the Cerius[2] molecular modelling package (Molecular Simulations, Inc.) and the MARVIN surface modelling program [1].

Results for several salts will be presented. Determination of the preferred slip planes is important in the study of powder processing, as milling enhances the exposure of the cleavage planes, thus modifying the sorption properties of the powder. A study of the effect of milling on the surface properties of the drug dl-propranolol hydrochloride, using inverse gas chromatography [2], has yielded results consistent with the slip plane predicted by molecular modelling.

P09.15.012 FACET FORMATION OF Ag_2S SMALL CRYSTALS EQUILIBRATED WITH SOLID Ag. T. Ohachi Department of Electrical Engineering, Doshisha University, Kyotanabe, Kyoto 610-0321 Japan

Self ordering of nano meter size crystals is currently studied extensively for application of quantum dots electronics devices. The understanding of equilibrium form (EF) needs the understanding of surface free energy density. The surface free energy density, which gives EF, is determined not only by the properties of bulk crystal but also the surface condition such as adsorption or contact substance at the interface. Facet formation of EF with sulfur vapor was determined only by vapor pressure and temperature. Facet formation, however, equilibrated with solid state silver is determined by temperature and the orientation difference between Ag2S and Ag. This paper reports experimental results obtained from the experiment mentioned the title of this abstract. Equilibrium crystals were prepared by annealing of single crystals of Ag2S grown by quenching from liquid Ag2S droplets within liquid silver. The high temperature phase of Ag2S, which is an ionic and electronic mixed conductor, has two crystal phases bcc and fcc and is easy to equilibrate even mm size.[1][2] Liquid droplets of Ag2S, which were nucleated in liquid silver, solidified after liquid silver solidification. The grain size of the matrix silver became large during annealing experiment. After the formation of the large grain size of the matrix silver, the Ag2S crystals, which were in the matrix silver, were melted and crystallized again to much the orientation of the matrix silver and equilibrated. Crystal shape was observed by scanning electron microscape at a scanning room temprature after removing the matrix silber. Above 700 deg C {111} facet of fcc Ag2S was obtained when 3 axis(2 axis) crystal orientations of the matrix Ag and fcc Ag2S were coincide. Only one axis coincidence formed circle disk of two facets. On nealing below 700 deg C rounded EF with {110} facets a belonging to bcc Ag2S were obtained.

P12.15.001 THE TWINS FORMATION DURING LEC GROWTH OF GaAs AND InAs CRYSTALS. V.G. Kossoushkin , Institute of Technics and Technologies, Kaluga, Russia, 248001, p/b 323, Kaluga, Russia.

One of the difficulties in the growth of GaAs and InAs single crystals is the strong tendency to twin. The twin formation during crystal growth has been correlated to many growth factors. The probability of twinning can be suppressed to a lower value by optimizing of the growth factors but the mechanism involved for the twin formation is not well understood at present.

The GaAs and InAs single crystals were grown by the LEC method with careful control of growth conditions. We used new method of temperature measurement in subcrystalline region during all crystal growth process. More than sixty crystals, some with twins and some twin-free were cut into {110} wafers. The {110} wafers were parallel to the growth direction and perpendicular to the twin boundary. The striations, facets and twin boundaries on the surface revealed by diluted Sirtl-like solution under light illumination (DSL solution) were observed by optical microscopy.

From chemical etching study it can be concluded that the growth conditions, which result in the generation of large irregular facets, also favor the formation of twins. However, the facets are not necessarily the nucleation sites of twins. Our results suggest that the 60^0 rotation twin has lower energy that the inversion twin.

In some crystals twinning begin at the facets and were found to depend on the peripheral interface shape, independent of the shape of the central parts. Twinning occurs during shoulder growth when facets extend deeply into the crystal and temperature fluctuations cause frequent meltbacks. The use of 1MHz ultrasonic vibrations was found to prevent twinning by stabilizing the growth conditions near crystal -melt interface. This results confirm that control of the growth interface shape is the key in the technology of crystal growth. The twinning can be reduce by the special low energetic influences.

P12.15.002 ON THE NATURE OF TWINNING. Robert A. Sparks, Bruker-AXS, Inc., 6300 Enterprise Lane, Madison WI, 53719, USA and Victor G. Young Jr., Department of Chemistry, University of Minnesota, 207 Pleasant St. S. E. Minneapolis, MN 55455, USA

Using the Bruker SMART CCD diffractometer it is almost always possible to solve and refine the crystal structures of twinned samples. It is also often possible to determine the type of twinning present and the molecular nature of the interface between the twin components.

With special twin software, TWINDX and TWUTIL, it is possible to determine the indices for each observed reflection for each twin component. With the lattice parameter least square procedure in the program, SMART, it is sometimes possible to measure the crystal center for each twin component. With the program, TWROT, it is possible to determine the twin axis and the angle of rotation about this twin axis. With the integration program, SAINT, the reflection intensities are obtained for all reflections for each twin component. With the program, TWHKL, the reflection intensities are merged into an HKLF5 file that the program SHELXTL can use to refine the atomic parameters of the twinned crystal structure. It is usually possible to solve and refine the crystal structure of most twinned samples with a precision almost as good as that obtained for single crystals.

By viewing the packing diagram from many different directions it is often possible to determine the nature of the bonding across the twin interface.

Examples are given of the use of these procedures. From the results of crystal structure determinations of many twinned samples conclusions concerning the nature of twinning are presented.

16. CHARACTERISATION OF DEFECTS, MICROSTRUCTURES AND TEXTURES

P05.16.000 SUBSTITUTION IN Ta_3O_7F AND ITS EFFECTS ON TWINNING. L. Jahnberg, and M. Sundberg, Department of Inorganic Chemistry, Arrhenius laboratory, Stockholm University, S-10691 Stockholm, Sweden.

The low-temperature form of Ta_3O_7F [1], as well as the high-pressure form of Nb_3O_7F [2], has a structure related to U_3O_8. It can be described as consisting of pentagonal bipyramids and octahedra, sharing edges and corners in the (001) plane. The polyhedra are repeated in the [001] direction by corner sharing. The ratio octahedra to bipyramids is 1:2.

In this structure the metal atoms can to some extent be replaced by titanium or zirconium. Since titanium occurs six-coordinated, the composition $TiTa_2O_6F_2$ was expected to be possible. It was synthesised from $TiO_2{\cdot}2TaO_2F$ in Pt-tubes. The obtained unit cell dimensions, a=6.394, b=10.487 and c = 3.888 Å, are somewhat shorter than those given in ref. 1.

EDS analysis using a JEOL 2000 FX II / LINK OX-200 microscope showed the Ti content to be approximately 28 atom% e.g. slightly less than 1/3, which agrees well with a small weight loss in the preparation.

A Rietveld refinement on powder diffractometer data and with 85% titanium in the octahedral position gave the R_F-value 0.089. This agreement was reasonable considering the problematic peak shapes from the sample which probably was due to extensive twinning and defects. Since the orthorhombic structure has a pseudohexagonal symmetry it has a tendency to grow as twins. This tendency seems to increase with titanium in the octahedra.

HRTEM images show alternating strings of two twins with the (110) plane as twin plane. This growing has a similarity to the periodicity in low-Ta_2O_5. Also substitution with zirconium has been performed and found to have a stabilizing effect on this modification of Ta_3O_7F and Nb_3O_7F.

P05.16.001 SIMULATION OF X-RAY DIFFRACTION PATTERNS OF A ONE-DIMENSIONAL DELTA-CRYSTAL. I.A. Kasatkin, Dept. of Crystallography St. Petersburg State University, Universitetskaya nab. 7/9, 199034, Saint-Petersburg, Russia.

Mixed crystals grown under non-stationary conditions are always inhomogeneous and can show a gradient of composition along a direction of growth resulting in a gradient of lattice spacing. Such crystals display some specific features of diffraction patterns if the change in lattice constant is about 1 % per cm. If properly cut and bent, they can serve as active elements of focusing monochromators, lenses, and other X-ray optic devices [1]. It is desirable to have a method for testing the value of gradient in as-grown delta-crystals.

A model has been designed [2] that allows to predict the distribution of the intensity of X-rays diffracted by a single crystal along a given direction in reciprocal space that is parallel to the direction of gradient. The intensity of the beam scattered by the crystal under a given Bragg angle is calculated as a sum of the intensities scattered by different "homogeneous" regions, each of which consists of a number of coherent domains with their sizes distributed according to a certain law. A region is characterised by a mean lattice constant that changes stepwise with the position (depth from the surface) according to the value of gradient. The absorption of X-rays by a crystal, the variability of the lattice constant gradient and the shape of instrumental function of diffractometer are taken into account in the model.

The profiles of 0k0 reflections from the delta-crystal of $(K_xRb_{1-x})C_8H_5O_4$ (x changes from 0 at the seed to 0.25 at the surface) [3] have been simulated with considerable precision. The values of gradient obtained were found to be close to those measured directly. The work was supported by RFBR.

P05.16.002 STRAIN-INDUCED INTERACTIONS OF β-STABILISING SUBSTITUTIONAL IMPURITY ATOMS IN H.C.P.-TITANIUM MATRIX. S.V. Shevchenko, V. A. Tatarenko, N.S. Kosenko, and C.L. Tsynman. Institute for Metal Physics, National Academy of Sciences of the Ukraine, 252142, 36 Vernadsky blvd. Kiev, Ukraine.

An instability with respect to the phase transformations in h.c.p.-Ti alloys with isomorphous (Mo, Ta, Nb) and eutectoid (Fe, Cr) β-stabilising elements is studied by analysis of the strain-induced and «electrochemical» interatomic interactions of substitutional impurity atoms, as well as related microstructural features of the martensite in binary titanium alloys.

The method of static concentration waves is used to describe impurity subsystem distribution. Dependencies of the «mixing»-energies Fourier-components' matrix eigenvalues along 12 main directions within the Brillouin zone are obtained. Analysis of these dependencies had shown that the alloys under consideration are unstable, and an atomic ordering with formation of antiphase isostructure domains is expected; besides, bulk modulations in substitutional atom distribution for these systems must occur within the basal plane, but along the corresponding directions. It has been found that the strain-induced contribution to the impurity—impurity interaction energy in α-Ti has a remarkable value and is about ~0.2-0.6 eV/atom in magnitude.

If the strain-induced interaction is considered only (which would be acceptable for the latest stages of decomposition), the h.c.p. solution should be unstable too, and the character of the phase transformations should be distinct. Isomorphous systems would be tend to spinodal decomposition, and layered atomic ordering along the hexagonal axis would occur in eutectoid systems.

P05.16.003 MICROINDENTATION STUDIES OF THE CHALCO HALIDES OF ANTIMONY AND BISMUTH. G. Kanchana and D.Arivuoli, Department of Physics, Anna University, Chennai-600 025, India.

Group Vb chalcohalides show interesting properties like ferro-elecity, semi-conducting and photo-conductivity and some of the crystals also piezoelectric and pyro-electric properties. The mechanical properties of these compounds have not been studied in detail due to the difficulty in growing larger size crystals. The compounds show needle morphology due to inherent chain type structure along the c-axis and hence higher growth rate along c direction than the other directions. The mechanical properties of the larger size single crystals, grown both by using vapour phase technique and gel growth technique, were studied using pyramidal vicker's indentation technique. The indentations were carried out along the (110) axis for all the crystals. The micro-hardness increased with increase of load and exhibited a constant value after a particular load. The hardness was found to decrease on annealing the compounds at different temperatures but below the dissociation temperature of the volatile compounds. The dislocation density was also found to decrease slightly with

annealing temperature. The surface of the indented regions at various loads was studied using SEM and also etching the crystals after indentation. In some of the crystals crack was found to propagate on increasing the load and hence the other related mechanical properties as brittleness index and fracture toughness were also deduced. An empirical correlation of the hardness with inter-planar spacing cell volume and bond energy were found for the compounds exhibiting the same crystallographic structure.

P05.16.004 RIETVELD REFINEMENT WITH WAVELET COMPRESSED DATA SETS. Lubo Smrčok, Institute of Inorganic Chemistry, SAS, SK-842 36 Bratislava, Slovak Republic

Recording of experimental data is one of the crucial steps in Rietveld refinement. The most widely accepted procedure prescribes to scan a pattern using an arbitrarily chosen, but a constant step, typically equal to hundredths of 2Θ. Such a simple strategy leads to oversampling, which is mostly ignored. The aim of this study was to explore how wavelet compressed data sets mimic the original ones in Rietveld refinement.

Crystal structures of triclinic kaolinite, cubic HMT and a part of the structure of a monoclinic rare sugar were refined using wavelet compressed sets of intensities. Wavelets are a family of basis functions which can be used to approximate measured signals either in one, or in multiple dimensions. Compression of intensities sets was accomplished by a discrete wavelet transform (DWT) [1] using Daubechies4 [2] wavelet. The original sets consisting of 4096 intensities were step-by-step compressed to 2048, 1024, 512 and 256 intensities, which were the inputs to refinements. It was found that accuracy of refined positional parameters did not change significantly even f the compression ratio reached 8:1, or 16:1. Similarly, quantitative phase analysis of a three-components mixture done by Rietveld method provided very close estimates of phase composition for compression ratios 2:1 and 4:1.

Application of DWT compressed data reduced the time needed for a refinement to 50-60% without significant loss of information [3]. This procedure may accelerate molecular modelling based on powder data, or speed up introductory steps of Rietveld refinements with extensive data/parameters sets.

P05.16.005 GRAIN BOUNDARY MAPS FROM EPIFLUORESCENCE SIGNALS OF EUROPIUM IONS INTO ALKALINE HALIDE CRYSTALS. A.E. Cordero-Borboa, Instituto de Física, UNAM, A.P. 20-364, D.A. Obregón, México D.F. 01000, México, and L.F. Jiménez-García, Facultad de Ciencias, UNAM, Cd. Universitaria, México D.F., México.

A simple method to make visible the three dimensional array of grain boundaries in transparent crystals has been developed and applied to the study of the architecture of grain boundaries in NaCl, KCl, RbCl and mixed alkaline halide crystals grown by the Czrochalski technique. In this method the grain boundaries are visible under an epifluorescence microscope by exciting the emission spectra of europium ions previously added as impurities to the melts from the which the crystals are going to grow. The as-grown crystals are heated and quenched to assure an hazardous distribution of the europium ions into the crystal matrices. Then the crystals are long annealed to allow the europium ions to gently move and found each other into the crystal lattices up to form europium chloride aggregates of microscopic size. These aggregates grow preferently at the grain boundaries of the alkaline halide crystals due to the mechanical relaxation of the stress in these boundaries. Three dimensional grain boundary maps for NaCl, KCl, RbCl and a mixed crystal particles are presented. These maps are accompanied by and X-ray diffraction study by using Weissenberg and Buerger-precession photographs.

P05.16.006 MEASUREMENTS OF BIREFRINGENCE IN NONHOMOGENOUS SAMPLES. M.A. Geday, W. Kaminsky and A.M. Glazer Department of Physics, Clarendon Laboratory, University of Oxford, Parks Road, Oxford OX1 3PU, UK.

A previously presented optical imaging system [1] has been revised and a Windows application has been written to derive and analyse birefringence data. Birefringence (= difference between refractive indices n2-n1 as a result of the anisotropy of the medium) is described by extinction angles and a phase difference (delta = (n2-n1)*L*2pi/lambda, where L is the thickness of the sample and lambda is the wavelength of the light).

The system is capable of determining the birefringence, its orientation and the absorption for each pixel within an image. The data are presented as colour coded images.

The system comprising a rotating polariser and a circular analyser was fitted to an optical microscope. Images of any transparent object are generated using a CCD-camera connected to a PC.

The new code has been extended to correct for polarising imperfections in the light path, and thus provides data of a higher quality needed to calculate the phase difference beyond the first order. This is done by a new algorithm based on comparisons between data generated at different wavelengths.

As examples conoscopic and orthoscopic images of mineral samples, crystals and biological specimens will be shown.

P05.16.007 THREE-FOLD TWINNED PARTICLES IN FE ION IMPLANTED GaAs. K. Sun, Structural Chemistry, Stockholm University, S-106 91 Stockholm, Sweden; Beijing Laboratory of Electron Microscopy, Chinese Academy of Sciences, 100080 Beijing, China.

In the study of iron ions implanted single crystal (100) GaAs wafers, submicron three-fold twinned particles were found in the ion implanted layers. These twins have been confirmed by dark-field electron microscopy and high resolution electron microscopy. The morphologies of these particles are mostly hexagonal cylinders, consisting of three pairs of large twins. Stacking faults were observed inside each part of the twins. The GaAs wafers were implanted with Fe ions with a total dose of 5´1017 Fe+/cm2 at an energy of 100 KeV. They were sealed in evacuated silica tubes and then furnace annealed at 600 °C for ten hours. The compositions of these particles were measured by energy dispersive X-ray analysis with ~97 at.% Ga, ~ 3 at.% Fe and ~ 2 at.% As (Ga-rich phase). Selected area electron diffraction and zone axis microdiffraction analysis indicated this Ga-rich phase is primitive orthorhombic. Its lattice parameters are about a = 0.46 nm , b = 0.89 nm, and c = 0.79 nm.

The Ga-rich phase is stable under the electron beam irradiation. But it is different from those usually found in Ga-As-Fe bulk materials [1] or in Fe ions implanted and rapidly thermal annealed layers of single crystal GaAs wafers [2]. In both two cases, only two different Fe-rich hexagonal Fe_3GaAs phases (H1: $P6_3/mmc$, a = 0.4006 nm, c = 0.5040 nm and H2: $P6_3/mmc$, a = 0.8012 nm and c = 0.5040 nm) had been found.

P05.16.008 PHASE INTERGROWTH WITHIN OH-BEARING INCLUSIONS IN EXPERIMENTALLY OXIDIZED OLIVINE: NANOMETER-SCALE INVESTIGATION. N.R.Khisina, Institute of Geochemistry and Analytical Chemistry of Russian Academy of Sciences, Moscow117975, Russia; R.Wirth, GeoForschungsZentrum Potsdam, Potsdam D-14473, Germany.

Olivine grain of natural origin annealed in a laboratory at 700 C in air was investigated by TEM including HRTEM, AEM, EELS SAED and CBED technique. Inclusions up to several hundred nanometers in size were observed in ion-thinned (100) section of the grain. The inclusions were of hexagon-like shape with the coherent inclusion/matrix interfaces parallel to (010), +/-(01-1), +/-(011) of the olivine matrix and exhibitted a chemical separation by Mg and Fe with a Fe-rich Mg-poor silicate core and a rim close by composition to the olivine matrix. Sharp coherent core/rim boundaries were observed parallel to (001), (010), +/-(021), +/-(021-) of olivine matrix with a strong moire patterns in the core. EELS spectroscopy data indicated a presence of water and/or Fe3+ in a core. SAED and CBED patterns were obtained with the electron beam parallel to [100], [2-11] and [31-1-] directions of the olivine matrix and a superposition of reflections from several phases was observed: olivine matrix (m); SiO2 beta-crystobalite (cr) and FeOOH feroxihite (f) in the core of inclusions; a secondary olivine (ol) in the rim of inclusions; with (100)m // (001)f // (111)cr // (100)ol; [010]m // [11-0]f // [110]cr // [010]ol. Inside the core the f and cr layers were found to be alternated along [100]ol. Such a complex microstructure of the inclusions is interpreted as a solid state transformation of inclusions created by a precursor phase like a hydrous Mg-silicate (HMS). The transformation of HMS under experimental annealing is assumed to involve the processes of oxidation and partial dehydratation of the precursor phase accompanied by a phase separation inside inclusions and Mg-Fe exchange between the Fe-free HMS inclusions and Fe-bearing olivine matrix.

P05.16.009 STRUCTURAL STUDIES OF QUANTUM DOTS BY TEM. W. Neumann, H. Kirmse, R. Schneider, Institute of Physics, Chair of Crystallography, Humboldt University of Berlin, Invalidenstrasse 110, D-10115 Berlin, Germany, and K. Scheerschmidt, D. Conrad, Max Planck Institute of Microstructure Physics, Weinberg 2, D-06120 Halle, Germany.

The optoelectronic properties of quantum dot (QD) test and device structures are essentially controlled by the structural perfection of the individual QDs, including their size, shape, and arrangement, as well as by their chemical composition. Owing to typical QD's dimensions of some nanometres transmission electron microscope (TEM) techniques have to be applied to elucidate the above-mentioned peculiarities.

Various II-VI compound semiconductor QD samples were investigated in detail by diffraction-contrast and high-resolution TEM imaging, where information on the size distribution, arrangement, and orientation relationship with respect to the wetting layer was particularly gained in plan view, and on the nanocrystal morphology in cross-section [1]. Since the image contrast visible in the QD regions is strongly influenced by the strain field arising from the lattice mismatch image interpretation was performed by means of image processing and computer simulation. Several crystallographic structure models, i.e. complete and truncated pyramids with different facets and different orientations to the underlying layer, were taken into account. The whole supercell used to describe the complex materials system (substrate, wetting layer with quantum dot, capping layer) was energetically relaxed by molecular dynamics calculations [2]. Simulated diffraction-contrast and high-resolution images are compared with the experimental findings.

P05.16.010 MICRODOMAIN STRUCTURE IN Fe_2O_3-DOPED ZnO AND THE FORMATION OF SPINEL. F. Wolf and W. Mader, Institut für Anorganische Chemie der Universität Bonn, Römerstr. 164, 53117 Bonn, Germany

Modulated structures in doped ZnO ceramics have been discussed in the literature [1-4]. However, the nature of the defect microstructure has not yet been clarified. In the present study zinc oxide crystals were prepared at 1200 C via conventional solid state route from powder mixtures of ZnO with 1 mol% and 12.5 mol% Fe_2O_3, respectively. The crystals were investigated by means of transmission electron microscopy. Elemental maps were calculated from energy-specific images obtained with a post-column electron energy imaging filter (GIF).

Typical are planar faults of two types: (i) faults parallel to the basal plane, {0001}, and (ii) faults parallel to pyramidal planes, $\{2\bar{1}\bar{1}5\}$. All these defects were identified as inversion domain boundaries (IDBs) resulting in an inversion domain microstructure. This was proved by dark field imaging using the {0002} reflections and by microdiffraction analysis from single domains. The elemental maps reveal the additive to be preferentially incorporated into the inversion domain boundaries.

The higher concentration (12.5 mol% Fe_2O_3) leads to a microstructure with alternating ZnO and spinel layers, where the ZnO layers still contain micro-domains. The crystallographic orientation relationship is: $(0001)_{ZnO} \parallel (111)_{ZnFe2O4}$ and $[2\bar{1}\bar{1}0]_{ZnO} \parallel [1\bar{1}0]_{ZnFe2O4}$. Hence, the close- packed planes and thus also the directions of the oxygen sublattices in both crystals are parallel.

The crystals with low additive concentration (1 mol% Fe_2O_3) cause diffraction streaks and diffuse lines which can be interpreted to be caused by lattice mismatch between ZnO and $ZnFe_2O_4$. Hence, the defects may be considered as nucleation sites of spinel.

P05.16.011 IN SITU INVESTIGATION OF DEFORMED ALUMINIUM TOPOGRAPHY. Afanasyev V. [1], Semukhin B., Zuev L [2], [1] Applied Mathematics and Cybernetic Faculty,Tomsk State University, [2] Department of Strenght Physics,Institute of Strength Physics and Material Science Siberian Branch of Russian Academy of Sciences, [3] Department of Strenght Physics,Institute of Strength Physics and Material Science Siberian Branch of Russian Academy of Sciences

Using a modified technique of the Fujiwara X-ray topography, the evolution of 200 and 311 images of coarse-grained aluminium specimens under deformation has been examined. A study has been made of the initial stage of deformation during which no marked changes occur in the

structure or substructure of the material investigated. The study was made on an Instron-1185 test machine with one immovable clamp using aluminium specimens having grain size of 1 - 3 cm. By specimen deformation, the position of the Lauer spot was defined for a large-sized grain of the working portion of the polycrystalline specimen and the rate of ultrasound propagation was measured simultaneously at the same point, the latter quantity being a structure-sensitive one. A microfocus tube having a 40 mm focus and a copper anode was used as an X-ray source.

As a result of the study it has been found that at the initial stage of plastic deformation, the material's substructure undergoes a change, which is manifested in rotations of individual grain volumes.With increasing level of deformation, the rate of ultrasound propagation also grows, which might be attributed to greater crystallite perfection due to grain volumes rotation. As the level of deformation, e, approaches 0.5 %, the local rotations become readily detectable.

Analysis of the electron density distribution over the grain area allows the microvolume sizes involved in the process of deformation to be evaluated; they are found to be a few hundreds of microns. Thus, using a modified technique of the Fujiwara X-ray topography, in situ investigations of plastic deformation can be carried out to yield scale parameters of the process that give an insight into the physical laws governing deformation of solids.

P05.16.012 FORMATION OF A RADIATION POINT DEFECTS ENSEMBLE IN THIN SI^+-DOPED GAAS LAYERS. K.D. Chtcherbatchev, V.T. Bublik, Yu.N. Parkhomenko, Moscow State Institute of Steel and Alloys, Leninskii pr.,4, 117936 Moscow, Russian Federation.

The formation of a radiation point defects ensemble in SI-GaAs (001) wafers that were implanted by Si^+ ions at 50 keV and various doses ($1\cdot10^{15}$ and $1\cdot10^{14}$ cm^{-2}) and annealed during 10 min at 850°C in arsine air was studied by high-resolution X-ray diffraction (HRXRD). Distribution of the implanted dopant was monitored by the secondary ion mass spectrometry (SIMS) method. Distribution of radiation point defects causes the distribution of strain in the distorted subsurface layer. Thus, an analysis of the strain depth profiles was used for an explanation of the behaviour of point defects in as-implanted and annealed samples. The Frenkel type defect is assumed to be a major one in irradiated samples. To reconstruct the strain depth profiles the diffraction patterns were fitted using the simulation software based on the theory of a dynamical diffraction. The strain depth profiles were found out to be extremely close in as implanted samples for both doses despite the tenfold difference in doses. Nevertheless, the analysis of an X-ray diffuse scattering showed that the total concentration of radiation point defects must be greater for the sample implanted by the highest dose. It can be explained by running of two processes that plays an essential role in the formation of defect layer during implantation. The first one is an annihilation that reduces the concentration of radiation point defects. Another one is the sink of the most mobile interstitials to the surface. It leads to the disbalance of interstitial and vacancy components of Frenkel's pairs and formation of the thin subsurface layer enriched by vacancy type point defects. The thickness of the layer increases after annealing. This layer is stable that can be caused by small mobility of vacancies. This layer is shown influence on redistribution of implanted impurity and stimulates diffusion of the impurity to the surface.

P05.16.013 CHEMICAL AND CRYSTALLOGRAPHIC CHARACTERIZATION OF SYNTHETIC CORUNDUM (Al_2O_3). C.Rinaudo and P.Orione, Dipartimento Scienze Mineralogiche e Petrologiche- Università di Torino, Via Valperga Caluso 35-10125 TORINO-Italy

Synthetic corundum samples, synthesized by Verneuil and Czochralski methods, have been studied as regards the chemical and crystallographic aspects.

The samples were "boules", colourless or red, cut in slices (about 1 mm in thickness) normal or parallel to the elongation axis. The different slices have been studied by optical microscopy, EDS, X-ray topography using white beam of the synchrotron radiation at LURE (Orsay-Paris). Analyses by Raman spectroscopy with a source in the NIR were also performed.

For all the examined samples, independently from the growth method, the slices obtained from the first-grown parts of the boule resulted single crystals, but the X ray topography revealed disorientation in different regions of a given slice. Studying the slices from the middle part and from the top of the boule, the samples were no longer single crystals but a trend to crack into subparallel domains were evidentiated.

Raman spectroscopy was applied on the slices with different orientation with respect to the laser source and the obtained results have been related to the crystallographic characteristics of the slices in the different orientations.

All the observed phenomena will be discussed taking into account the different stages of the growth process and a practical application on cut gem stones used for gemmmological applications will be shown.

P05.16.014 BRAGG-CASE SECTION IMAGES OF STACKING FAULTS IN DIAMOND. Moreton Moore and W.K. Wierzchowski[1], Royal Holloway University of London, Egham, Surrey, TW20 0EX, U.K., [1]Permanent address: Institute of Electronic Materials Technology, Warsaw, POLAND.

Bragg-case section images of stacking faults were obtained at experimental Station 7.6 at the synchrotron source of the CCLRC Daresbury Laboratory. The sample was a $4 \times 4 \times 0.7$ mm^3 slab prepared from a large truncated octahedral synthetic diamond grown by De Beers, which was used by us previously for studying plane-wave images of stacking faults in Bragg-case [1]. The sample was cut using a laser saw and polished along the (001) crystallographic planes.

Bragg-case section topographs of stacking faults were obtained using a well-collimated white synchrotron beam using the 400 symmetrical reflection of wavelength 1.26 Å (with a very small amount of higher harmonics). The images of the stacking faults may be classified as corresponding to the Bragg-Laue case, *i.e.* the wavefields decomposed by the stacking fault next undergo diffraction in the transmission case. The obtained images contained a series of distinct fringes appearing behind the direct image of the intersection of the stacking fault with the incident beam.

The experimental images of the stacking faults were compared with simulated theoretical images obtained by numerical integration of the Takagi-Taupin equations, where the stacking fault was approximated by a suitable step change of phase in the Fourier coefficient of dielectric susceptibility. Good agreement between the theory and the experiments was obtained. The formation of different parts of the image was also analyzed by visualisation of the distribution of $|D_o|^2$ and $|D_g|^2$ intensities in the plane of diffraction. The latter allowed us to find some analogies with the better known formation of images of stacking faults in transmission, avoiding difficulties associated with the validity of the plane-wave approximation.

P05.16.015 A HIGH RESOLUTION DIFFRACTION STUDY OF THE 222 'FORBIDDEN' REFLECTION OF DIAMOND. John S. Reid, School of Physics, University of Aberdeen, Aberdeen AB24 3UE, Scotland, Moreton Moore and Mina Golshan, Physics Department, Royal Holloway, University of London, Egham TW20 0EX, UK, Grzegorz Kowalski, Institute of Experimental Physics, University of Warsaw, Warsaw 00-681, Poland, Steve Collins and Bridget Murphy, CLRC Daresbury Laboratory, Daresbury, Warrington WA4 4AD, UK.

Recent theoretical calculations [1] of forbidden reflections suggest that such reflections are not actually forbidden but have high intensities and extremely narrow angular widths. We report here experimental evidence that supports the general predictions of this theory, using high-resolution reciprocal space mapping with 1 Å synchrotron X-rays at the Daresbury station 16.3. The specimens were (1) a type Ia natural diamond, (2) a single crystal of synthetic diamond grown under conditions of high pressure and high temperature by the reconstitution technique. In addition we took measurements on a 'perfect' single crystal of Si. All maps obtained from three different specimens confirm the existence of the forbidden 222 reflection in the diamond structure. A narrow sharp peak characteristic of this reflection has been displayed in each of the maps. However, it is noticeable that in the case of silicon the peak was smaller than that of both natural and synthetic diamonds, where the intensity of the reflection was increased by strain associated with defects. We believe that the forbidden reflection structure in diamond could be a sensitive measure of strain induced by cluster impurities and other defects.

P05.16.016 IN-SITU DOUBLE CRYSTAL X-RAY TOPOGRAPHIC IMAGING OF AS-GROWING CRYSTAL SURFACES. R. M. Vrcelj, P. J. Halfpenny, D. B. Sheen, J. N. Sherwood, Department of Pure and Applied Chemistry, University of Strathclyde, Thomas Graham Building, 295 Cathedral Street, Glasgow, G1 1XL

The (111) face of potassium aluminium sulphate dodecahydrate (potash alum) has been studied growing from an aqueous solution in-situ by both reflection and double crystal topographic methods utilising synchrotron sources. Comparison of these two methods shows that although the experimental layout and geometrical configuration for a simple reflection experiment are easier to maintain, the quality of results of the double crystal experiments exceed those from simple reflection.

The double crystal images show that it is possible to follow the growth processes of a crystal whether it has a well preserved or damaged surface, as long as the growth conditions are suitable for slow growth of the crystal surface. Much useful information, such as areas where refeacetting occur, the sites of emergent defects and areas of high perfection of the crystal can be clearly seen.

The ability to capture such images is a combination of a variety of factors, high photon flux from a synchrotron source, the design of an optimised cell and the availability of a choice of suitable reflections are among those of importance.

P05.16.017 OBSERVATION OF X-RAY ANOMALOUS TRANSMISSION EFFECT IN TUNGSTEN CRYSTALS. I.K.Bdikin, S.I.Bozhko and V.N.Semenov, Institute of Solid State Physicists, Chernogolovka, Moscow distr.,142432, Russia.

Dynamic diffraction effects are realize in perfect crystals only. At present there is limited number of crystals, technology of growth that, allows to reach to be required for the dynamic diffraction density of defects, not more $10^6 sm^{-2}$. Single crystals in which high melting temperature are grow with certain difficulty. This is connected with the small energy of arising the defects of lattice and with technical difficulties of getting the small temperature gradients when growing the crystals. Modern methods of preparing single crystals of tungsten allow get samples with density of defects less $10^4 sm^{-2}$ [1]. In given work are present results on observing dynamic diffraction on such crystals.

Crystals of tungsten by mechanical and electro polished were prepare plates by size $20x10x0.3mm^3$. Their broad grain oriented with the plane (110). X-rays anomalous transmission effect (Borrmann effect) in crystal tungsten realizes in scheme on transmission on copper and molybdenum radiation. Calculation on kinematics theory shows that for copper radiation at thickness of sample 0.3 mm ($\mu t \sim 98$) absorption is 10^{-43}. Under available X-ray sources to get intensity on the transmission impossible, however in dynamical perfect crystals of tungsten we easily realize topography in transmission geometry in copper radiation on (110) reflection. For molybdenum radiation exact measurements of factor of absorbing diffraction radiation $\mu_i t$=7.3. Design value of factor of line absorption tungsten by thickness 0.3mm on molybdenum radiation μt= 53.4 (μ/μ_i =7.3). Evident excess a relations μ/μ_i units be a direct effect of anomalous transmission of X-rays. However width of crocking curve determined in this case is ~50".

The interest presents using and development of theory the effects dynamic diffraction of X-ray for tungsten because it has Im3m simplest structure with two atoms in the unit cell and high X-ray absorption.

P05.16.018 X-RAY TOPOGRAPHY and SEM OBSERVATIONS OF $LnBa_2Cu_3O_{6+x}$ (Ln=Tm, Lu) SINGLE CRYSTALS. G.M.Rilov, Institute of Mineralogy and Petrology SB RAS, Novosibirsk 630090, Russia, and M.Yu.Kameneva, L.P.Kozeeva and A.N.Lavrov, Institute of Inorganic Chemistry SB RAS, University of Novosibirsk, Novosibirsk 630090, Russia

Using X-ray topography (XRT) and scanning electron microscopy (SEM) the microstructural features of high-temperature superconductors, $LnBa_2Cu_3O_{6+x}$ (123-Ln) with Ln=Tm, Lu single crystals, were studied. The crystals were grown by spontaneous crystallization from the flux and had an orthorhombic structure. For determination of the defects within the volume of the crystal XRT experiments were carried out by the transmission techniques with Mo K_α-radiation. The surface images were received by "reflection" techniques with Cu K_α-radiation. Diffraction reflection curve method on the set of reflections 200, 020 and 006 was used too. High linear (1-2μm) and angular (several sec.) resolution in diffraction contrast images was achievable using microfocus source in combination with linear collimator.

The defects in the form of large blocks and twin domains elongated in <110> directions were revealed. The domains misorientation (1 degree for large lamels and 10-30 min for smaller ones) was obtained. Along [001] direction the crystals constituted 2-3 subparallel layers (misorientation about 30 min.) with different defect images. No contrast directly attributable to growth screw dislocations on the (001) faces was detectable on XRT. To determine such defects the etching method was used. Besides the pyramidal etch pits associated with growth spirals numerous flat etch pits bounded by {100}/{010} walls were observed by SEM. Demonstrating the similar patterns the topographs of 006-type reflections gave evidence of their tilting.

Data obtained for crystals growing in different conditions was vital for conclusion about mechanism and optimization of the growth process.

The work is partially supported by grants of Federal directed Program K0042, “Superconductivity” Program № 98009 and “Russia Universities” № 1785.

P05.16.019 DISORDERED STRUCTURES BY HIGH RESOLUTION POWDER DIFFRACTION. R.E. Dinnebier, Laboratory of Crystallography, University of Bayreuth, D-95440 Bayreuth, Germany

According to a text book definition, the perfect crystal is a container in which the fundamental component (structural motif) is replicated in the 3-dimensions of space by a combination of symmetry operations and translations. On contrary, the real crystal has a number of defects and exhibits all kinds of disorder, where disorder means the distortion of translation symmetry. Disorder can be divided into two categories: static and dynamic disorder. Examples for static disorder are mosaic spread, surface defects (e.g. grain boundaries), substitution, point defects (e.g. Frenkel or Schottky type), planar defects (e.g. stacking faults), dislocations, impurities, lattice strain etc. Examples for dynamic disorder are reorientational jumps, thermal motion (translation + vibration), rotation of molecules, (continuous, stepwise, around axis, spherical) etc. With single crystal diffraction, it is often possible to detect certain types of disorder directly and to refine disordered crystal structures. In the case of powder data, the reduced content of information renders it quite complicated to model disorder. Nevertheless, in some cases, the occurrence and the type of disorder can be extracted from a high resolution powder pattern by analyzing diffuse scattering, additional lines inconsistent with space group symmetry, 'strange' line shapes, anisotropic peak broadening and reflection intensities. Examples of disordered structures will be given which have been solved from powder data by applying different methods like anomalous dispersion, the split atom model, Rigid Body Rietveld refinement, the maximum entropy method, energy minimization, spherical shell form factors, anisotropical FWHM distribution, pattern simulation, investigation of anisotropic temperature factors etc.

P05.16.020 THE ATOMIC-FORCE MICROSCOPY INVESTIGATION OF DYNAMICS VARIATIONS OF THE NEW FORMED CRYSTAL SURFACES. V.A. Liopo, A.F. Sen'ko, Physics & Ingineering Department of Grodno State University, Ozheshko st. 22, Grodno 230023, Belarus, and A.U. Sheleg, A.V. Kartavtzev, Institute of Solid State and Semiconductor Physics National Academy of Sciences of Belarus, P.Brovka st. 17, Minsk 220072, Belarus.

The most important and perspective direction of the applying atomic-force microscopy (AFM) as a variety of scaning probe microscopy is the using for investigation dynamics of changes (DC) of new formed surfaces (NFS). The DC of surfaces activity was analysed in the same points. We investigated NFS of monocrystals with perfect cleavage. For our analysis we took the di-and trioctahedral mica crystals. The new formed surfaces of these natural crystals are constructed by silicon-oxigen tetrahedron faces with random interlayer cations distributions. Besides we researched the isostructural semiconductors $TlGaSe_2$ and TlInSSe crystals. $TlGaSe_2$ crystalls have the trilayers structure from Se tetrahedron with Ga atom in its center. Tetrahedrons form the layers parallel (001)…. Point group of mica and analysed by us semiconductors is $C2/_m$. The NFS are obtained by means splitting along cleavage plane of the crystals directly before AFM-investigation. We revealed the surfaces active islands with sizes from 1,2 μm to 580 nm. The high of surface adsorbtion production are about 20-50 nm. Besides these processes we discovered the going out of some part of matter from inner bulk crystal regions as usually near the surfaces defects. Together with these processes the degree of surface roughness changings take place. All processes on the juvenile crystals surfaces may go on about tens minutes. The surface changing processes are the most appreciable for new formed surfaces constructed by tetrahedron structural layers. The processes are less noticeable for nontetrahedral crystal surfaces and practically absent for juvenile surface of different glasses.

P05.16.021 CLUSTERIC STATES OF METALLIC MATERIALS INDUCED BY ION IRRADIATION. V.S. Khmelevskaya and V.G. Malynkin, Institute of Nuclear Power Engineering, Studgorodok 1, 249020, Obninsk, Kaluga region, Russia

The new states of metallic materials including solid solutions and pure metals (Fe-Ni, Fe-Cr-Ni, Ni-Cr, Cu-Ni, Fe-Cr, V-Ti-Cr, Zr, Ti) have been found after ion irradiation within a narrow range of radiation parameters, namely, doses, irradiation temperatures and flux intensities. The main their features are following: significant changes of X-ray diffraction patterns (splitting of X-ray peaks or characteristic changes of X-ray line forms) indicating an appearance of heterogeneity in a formerly homogeneous and equilibrium systems; accompanied changes of material properties including increase several times of microhardness; unusual morphology, in particular, an appearance of little (30-40 A) clusters in a initial matrix. Adding to this phenomena of a spatial self-organization are observed on different scale levels (registered by both optical and electron microscopical methods) [1]. The model is proposed based on consideration of local restructuring of a crystal lattice in a vicinity of a point defects (vacancies). In FCC crystal lattice coordinational polyhedron (cuboctahedron) transforms into an atom group with icosahedral symmetry, then little clusters of changed symmetry appear in a matrix. In BCC crystal lattice deformation along <111> axis leads to the formation of the Frank-Kasper polyhedron [2]. As computer experiments show it is possible to explain experimental results described by such crystal lattice transformation. The formation of these states is apparently universal phenomenon since it observed in various materials with FCC, BCC and HCP crystal lattices and after different types of irradiation, namely, in an accelerator (Ar+, 20-50 keV; Ni+, V+, 30-50 keV; Ar+, 1 MeV), by impulse or stationary plasma (Ar+).

P05.16.022 THE EFFECTS OF TEMPERATURE AND NACL CONCENTRATION ON THE CRYSTAL GROWTH OF TETRAGONAL LYSOZYME USI. L. Rong and T. Yamane [1], N. Niimura [2], [1] Department of Biotechnology, Graduate School of Engineering, Nagoya University, Chikusa-ku, Nagoya 464-8601, Japan, [2] Neutron in Biology, Advanced Science Research Center, Japan Atomic Energy Research Institute, Tokai-mura, Naka-gun, Ibaraki 319-1195, Japan

It is known that the Atomic force microscope (AFM), a relatively new and rapidly advancing technique, could be applied to obtain useful information for the crystallization of macromolecules. In 1992, Durbin and Carlson first demonstrated that the AFM could be used to observe growth steps on the surface of lysozyme crystals in mother liquor [1]. However, for most experiments to date, since the sample solution is not tightly sealed in avessel, evaporation of solvent water was a problem because slight changes in solution concentration could occur during a measurement. It is, therefore, difficult not only to investigate the crystal growth of a protein quantitatively, but also to carry out measurement of the crystal growth for a long period using an AFM. In order to solve this problem, sealed AFM vessel was developed, and quantitative and long-time measurements of crystal growth step rate of hen egg-white lysozyme (HEWL), were

carried out under several supersaturated conditions [2]. Furthermore, the effects of temperature and NaCl concentration on the crystal growth are determined with the sealed vessel.

Crystals were grown on a round cover glass with sitting drop method and 0.5-1.0mm crystals were selected for use in the AFM measurement (SPI 3800, Seiko Instruments Inc., Japan). The cover glass was fixed to the bottom of the sealed vessel with teflon screws. It was found that bunching of growth steps were often observed at higher temperature (more than 25 deg.C) and that bunching of growth steps do not occur by changing NaCl concentration or lysozyme concentration. This phenomenon has not been explained yet at present time. However, at least this implies that the effect of temperature is different from that of NaCl or lysozyme concentration on the aggregates of protein in solution. The aggregates of protein in solution might be an indicator relevant to the crystal growth mechanism of protein.

P05.16.023 PARAMETERS FOR ANALYSIS OF SURFACE ROUGHNESS AND MICRORELIEF MATERIALS BY AFM. A.L.Tolstikhina, Institute of Crystallography, Moscow 117333, Russia, and P.A. Arutyunov and V.N. Demidov, Moscow State Institute of Electronics and Mathematics, Moscow 109028, Russia.

The system of parameters for analysis of the roughness and microrelief of thin film surfaces and crystals by means of Atomic force microscopy is developed. The parameters are determined in the terms of classical statistics, spectral analysis and fractal geometry. We classify two groups of parameters: metric parameters (amplitude, functional and 3-dimensional parameters) and fractal ones. Amplitude parameters are the following: peak-to-peak value, average roughness, root-mean-square roughness, ten point height, surface skewness, surface kurtosis, function of kurtosis, autocorrelation function, power spectral density, coherence function, roughness correlation function, roughness hierarchy function, mean summit curvature, root mean square slope. Functional parameters are the following: mean summit curvature, root mean square slope, surface area ratio, surface bearing index, core fluid retention index, valley fluid retention index, reduced peak height, core roughness depth, reduced valley height, density of summits. Many of them are governed by international standards. The functional parameters unlike amplitude parameters classified microrelief and properties of a smooth surface. The 3-dimensional parameters are the radial wavelength index, texture direction, texture direction index, radial wavelength. This group allows to determine the surface anisotropy and structural periodicity. In the latter group, the numerical data of surface image are used after the discrete Fourier transformation. The atomic force microscopy images of various material surfaces and calculated dependencies of roughness parameters are presented.

P05.16.024 RECIPROCAL SPACE MAPPING OF MACROMOLECULAR CRYSTALS IN THE HOME LABORATORY. Edward H. Snell [1], Paul F. Fewster [2], Norman Andrew [2], Titus J. Boggon [3], Russell A. Judge [1], Marc L. Pusey [1], [1] NASA, Code ES 76, Bldg. 4464, Marshall Space Flight Center, Huntsville, AL 35812, [2] Philips Research Laboratories, Redhill, Surrey, RH1 5HA, England, [3] Chemistry Department, University of Manchester, Manchester, M13 9PL, England

Reciprocal space mapping techniques are used widely by the materials science community to provide physical information about their crystal samples. We have used similar methods at synchrotron sources to look at the quality of macromolecular crystals produced both on the ground and under microgravity conditions. The limited nature of synchrotron time s to explore the use of a high resolution materials research diffractometer to perform similar measurements in the home laboratory. Although the available intensity is much reduced due to the beam conditioning necessary for high reciprocal space resolution, lower resolution data can be collected in the same detail as the synchrotron source. Experiments can be optimized at home to make most benefit from synchrotron time available. Preliminary results including information on the mosaicity and internal strains from reciprocal space maps will be presented.

P05.16.025 SYNCHROTRON X-RAY RECIPROCAL SPACE MAPPING AND TOPOGRAPHY OF MACROMOLECULAR CRYSTAL QUALITY. Titus J. Boggon [1], John R. Helliwell, David Moorcroft [2], Russell A. Judge, Edward H. Snell [3], D. Peter Siddons [4], Vivian Stojanoff [5], [1] Department of Physiology and Biophysics, Mount Sinai School of Medicine, 1425 Madison Avenue, New York, NY 10029, USA, [2] Department of Chemistry, University of Manchester, Oxford Road, Manchester, M13 9PL, UK, [3] NASA Laboratory for Structural Biology, Code ES76, MSFC, Huntsville, AL 35812, USA, [4] NSLS, Brookhaven National Laboratory, Upton, New York, USA, [5] ESRF, BP220, Grenoble Cedex, France.

A comprehensive study of microgravity and ground grown chicken egg white lysozyme crystals is presented using synchrotron X-ray reciprocal space mapping and topography techniques. Microgravity crystals displayed, on average, reduced intrinsic mosaicities but increased delta d-star over their earth grown counterparts. Topographic analysis revealed that in the microgravity case the majority of the crystal was contributing to the peak of the reflection at the appropriate Bragg angle. In the earth case at the diffraction peak only a small volume of the crystal contributed to the intensity.

The techniques prove to be highly complementary with the reciprocal space mapping providing a quantitative measure of the crystal mosaicity and stress (or variation in lattice spacing) and the topography providing a qualitative overall assessment of the crystal in terms of its X-ray diffraction properties. Structural data collection was also carried out both at the synchrotron and in the laboratory.

P05.16.026 PREPARATION OF STM/AFM PROBES OF SPECIAL SHAPE WITH DIAMOND TIPS. A.N.Stepanova, E.I.Givargizov, and L.N.Obolenskaya, Institute of Crystallography, Russian Academy of Sciences, Moscow 117333, E.S.Mashkova and V.A.Molchanov, Moscow State University, Moscow 119899, M.E.Givargizov, Crystals and Technology, Ltd., Moscow 117333, Russia, and I.W.Rangelow, University of Kassel, Kassel 34132, Germany.

For investigations of submicron grooves with vertical walls, typical for microelectronic technologies, and of objects with coarse surfaces such as biological macromolecules special STM/AFM probes with small-diameter cylindrical or prismatic upper part of probes are necessary. Such probes have been prepared by growing of special-geometry single-crystalline silicon whiskers on (111)-oriented substrates by the vapour-liquid-solid mechanism. In order to prepare (111)-oriented cantilevers for AFM probes, special technologies have been used. From the whiskers grown, ultrasharp tips with curvature radii as small as several nanometers were prepared. The tips were coated by crystalline diamond by hot-filament chemical vapour deposition. The diamond coating was then sharpened by ion-beam bombardment. Curvature radii of diamond tips as small as 100 nanometers were obtained.

P05.16.027 PERIODICAL SYSTEM OF CRYSTALLOGRAPHIC INDEXES AS BASIS FOR TEXTURE OF GRAINS AND BOUNDARIES. V.I.Slavov, O.M.Naoumova and T.P.Jakovleva. Severstal JSC, Russia

The main topic presented here is a theoretical approach to orientational factors on basis of Periodical System of Crystallographic Indexes (PSCI). A crystallographic indexes may be represented in form of PSCI, which consists of 8 groups (G) in accordance with the laws of square indexes sum. The components of axial or planar texture are subdivided on 7 types (N) with a different positions of lattice direction <uvw> or lattice plane (hkl) of unit cell relatively to the main external axes. Any crystallographic orientation can be expressed by group's symmetry orientation (GSO) as four numbers ($NG_1G_2G_3$) in the three-dimensional pattern. Lots of GSO are exactly coincident with the 230 number of well-know space groups of crystals.

If the stress field acts on polycrystalline material, physical sense of crystallographic orientation consists in a resulting symmetry of the interaction between a crystallite and stress field. Lots of stress fields may be described by 14 symmetry groups of second-order tensors. On the basis of the superposition principle for crystalline body and stress field it may predict the grain orientation in terms of GSO.

A great number of Σ for special boundaries of cubic polycrystals with different misorientation axes was calculated using PSCI.

In the present paper we have shown that it is possibly to calculate different CSL at any values Σ, to classify CSL on definite groups and to represent crystalline materials under a new point of view PSCI.

P05.16.028 GROWTH AND CHARACTERISATION OF NEARLY PERFECT BISMUTH GERMANATE CRYSTALS. Krishan Lal[a], R.V.Anantha Murthy[a], M.Ravikumar[a], A.Choubey[a], G. Bhagavannarayana[a], Lyudmila Kharachenko[b], V. Shleguel[b], V. Guerasimov[b] and Yu. Shubin[b], [a]National Physical Laboratory, Dr. K. S. Krishnan Road, New Delhi 110012, India, [b]Institute of Inorganic Chemistry, SB RAS, Novosibirsk, Russia.

Bismuth Germanium Oxide (BGO) $Bi_3Ge_4O_{12}$ are grown from melt to meet the stringent requirements as scintillators for X-rays and γ-rays. Till recently, Bridgman method had been employed to grow BGO crystals with good degree of perfection. Recent efforts have shown that nearly perfect BGO single crystals can be grown by Low Thermal Gradient (LTG) Czochralski method with Automatic Weight Control Process [Murthy et al, J. Crystal Growth 1999]. For structural characterization, high-resolution X-ray diffractometry and topography methods were employed. Point defects and their clusters have been investigated by diffuse X-ray scattering measurements. The crystal growth system has been developed at IIC, Novosibirsk and the multi-crystal X-ray diffractometers employed in this study were developed at NPL. The crucible weighing system has an accuracy of 10 mg in 1 kg range and 50 mg in 25 kg range. The diameter control is effected through crucible weight control. The temperature gradient above the crystal – melt interface is negligible in a zone of ~4 cm. Platinum crucible was used to melt the charge, which was heated at a rate of 250^o C/h. Nearly perfect crystals were grown under following growth conditions: pulling rate - 2.5 mm/h, seed rotation rate - 38 rpm, growth rate - 30 g/h and post growth cooling rate - 150^o C/h. Crystal dimensions were ~ 80 mm long and ~ 40 mm in diameter [weighing ~ 800g]. Diffraction curves were quite sharp with typical half width values of ~9 arc sec in the central region. Some regions at the periphery had *very* low angle grain boundaries with angular tilts of only ~33 arc sec. Thermal annealing at elevated temperatures reduced the tilt angles and improvements in crystalline perfection were observed. Diffuse X-ray scattering measurements showed significant differences in defect structure with direction of growth. Variations in trace impurities in starting materials, which apparently led to different tinges, did not produce appreciable effect on the point defect clusters.

P05.16.029 DIFFUSE X-RAY SCATTERING STUDY OF POINT DEFECT CLUSTERS IN BISMUTH GERMANATE SINGLE CRYSTALS. G. Bhagavannarayana[1], A. Choubey[1], Yu. Shubin[2] and Krishan Lal[1], [1]National Physical Laboratory, Dr. K.S. Krishnan Road, New Delhi –12 . [2] Institute of Inorganic Chemistry, SB RAS, Novosibirsk, Russia.

Recently, it has been shown that nearly perfect crystals of bismuth germanate (BGO) can be grown by the newly developed low thermal gradient Czochralski technique [Murthy et al, J. Crystal Growth, in press]. It has been observed that BGO crystals are generally colourless (Type A), but a yellow tinge is often observed in some crystals (Type B) due to different impurities in the raw material. Fairly large volumes of specimens are free from boundaries and dislocations in both types of specimens. However, these crystals contain point defect clusters. Crystals grown along both [111] and [112] directions have been chosen as specimens. A multicrystal X-ray diffractometer set in (+,-,-,+) configuration with a well collimated and highly monochromated $MoK_{\alpha 1}$ beam as exploring beam and a high resolution diffuse X-ray scattering (DXS) measurement technique developed at NPL have been employed. DXS measurements were made in symmetrical Bragg geometry around 444 and 224 reciprocal lattice points (RLPs), respectively for the samples grown along [111] and [112] directions. Diffraction curves were recorded before DXS experiments. Both types of crystals gave quite narrow curves with half widths ~7 arc sec for 444 RLP and ~9 arc sec for 224 RLP [theoretical values for perfect BGO crystals = 1.3 arc sec (444 RLP) and 3.4 arc sec (224 RLP)]. Experimental data of DXS intensity could be analyzed by using a phenomenological model for small concentration of dislocation loops wherein the point defects are loosely clustered with weak interactions among them. From the analysis, cluster radius R_{cl}, cluster volume A_{cl} and the number of point defects within a cluster N_{cl} have been determined. There was no significant difference in the values of R_{cl}, A_{cl}, and N_{cl} for type A and type B crystals. However, growth direction had appreciable effect. Typical values of R_{cl}, A_{cl} and N_{cl} were respectively 7.4×10^{-5} cm, 8.3×10^{-17} cm^3, 2.86×10^4 (grown along [111]) and 3.6×10^{-5} cm, 2.78×10^{17} cm^3, 9.6×10^4 (grown along [112]).

P05.16.030 STRUCTURAL CHARACTERIZATION OF III-V HETEROSTRUCTURES BY HIGH-RESOLUTION X-RAY DIFFRACTION TECHNIQUES. Niranjana Goswami and Krishan Lal, National Physical Laboratory, New Delhi-110012, India, A. Vogt and H. L. Hartnagel, Institut fuer Hochfrequenztechnik, Technische Hochschule Darmstadt, D-64283 Darmstadt, Federal Republic of Germany.

GaSb/GaAs, GaAs/InAs/GaAs and GaAs/AlGaAs/GaAs structures for resonant tunnelling diodes and high frequency applications have been characterized by using high resolution X-ray diffractometry and topography. These heteroepitaxial films were grown by molecular beam epitaxy (MBE) on (100) semi-insulating GaAs substrates. The film thicknesses were in the range: ~ 4 nm – 5 μm. A five crystal X-ray diffractometer, developed at NPL was employed in (+, –, +) configuration with $MoK\alpha_1$ exploring beam and (400) diffracting planes in symmetrical Bragg geometry. The diffraction curves consisted of film and substrate peaks separated by a large angle of more than a degree in some cases. Half widths of diffraction curves of GaAs substrates were in the range: 14 – 22 arc sec, showing good crystalline quality of the starting wafer. Broad diffraction curves but single peaks were observed from the interface and film regions. Half widths of film diffraction curves were found to be in

the range: 164 – 527 arc sec, showing considerable stress at the interface. The stress could be relaxed through the introduction of buffer layers as revealed by the decrease of diffraction curve half widths. The observed angular separation between the substrate and film peaks were found to be not only due to lattice mismatch but also due to large angles between the lattice planes of the substrate and films. A methodology was developed for quantitative determination of these two mismatches. Two azimuthal orientations of the specimen were selected at which the direction of the diffraction vector was in the plane of diffraction. From the observed angular separations at the two azimuthal orientations, the lattice mismatch was determined quantitatively. These experiments lead to determine correct values of the composition of films. In multilayered structures, different layers are found to have different physical misorientations. In GaAs/InAs/GaAs structures, the lattice planes of the GaAs film and GaAs substrate had substantial tilt with respect to each other.

P05.16.031 HIGH RESOLUTION X-RAY DIFFRACTOMETRIC AND TOPOGRAPHIC STUDIES OF AS GROWN AND ANNEALED BGO CRYSTALS. A. Choubey[1], Yu. Shubin[2], G. Bhagavannarayana[1] and Krishan Lal[1], [1]National Physical Laboratory, Dr. K.S. Krishnan Road, New Delhi –12 . [2] Institute of Inorganic Chemistry, SB RAS, Novosibirsk, Russia.

Crystalline perfection of bismuth germanate (BGO) single crystals grown by the recently developed low thermal gradient (LTG) Czochralski technique has been investigated by double crystal X-ray diffractometry and topography techniques. A variation in the degree of perfection of crystals grown under different conditions was observed. Good number of the specimens were nearly perfect. Half widths of their diffraction curves were in the range 6.5-8.8 arc sec for (444) planes, 9-10 arc sec for (422) planes and 9-11 arc sec for (400) planes. These values are close to the theoretical values [1.3, 3.4 and 3.8 arc sec respectively for (444), (224) and (400) planes obtained from the plane wave dynamical theory of X-ray diffraction]. Some of the specimens contained *very* low angle boundaries. Diffraction curves showed two or more peaks with tilt angles in the range: 20-140 arc sec. To improve the perfection of these specimens, these were annealed at ~1000 ^{o}C. Duration of annealing was increased step wise from 8 hrs to 80 hrs. Traverse topographs and diffraction curves were recorded after each annealing step. A considerable improvement in crystalline perfection of the specimens was observed even after first 8 hrs of annealing. Some low angle boundaries were removed and angular separation between the boundaries decreased from 58 to 41 arc sec in a typical case. After 32 hrs of annealing, the degree of perfection of individual grains is slightly improved and the angular separation further decreased upto 39 arc sec. Further increase in annealing time did not improve any degree of perfection. Higher annealing temperature would be necessary to remove these boundaries.

P05.16.033 CHARACTERIZATION OF FERROELECTRIC DOMAIN WALLS BY WEAK BEAM AND HRTEM ELECTRON MICROSCOPY. P.A. Buffat, A. Sfera, M. Foeth and P. Stadelmann, Centre Interdépartemental de Microscopie Electronique, Ecole Polytechnique Fédérale de Lausanne, 1015 Lausanne, Switzerland

New means for quantitative interpretation of Weak Beam and High Resolution Transmission Electron Microscopy images have been developed to study extended interfaces. They are applied here to the thickness determination of ferroelectric domain walls in $PbTiO_3$ at room temperature and their broadening close to the ferroelectric to paraelectric transition temperature.

HRTEM is in principle a straightforward method to observe the position of atom rows in crystals. However most often black or white dots do not correspond to the precise atoms position. Image simulation based on models of the structure and of the microscope is required for interpretation. The atom position shift remains small and this very detailed information requires some mathematical approach to be summarised into a few numerical values. This technique is limited to the cases where interfaces can be oriented parallel to the electron beam while remaining on a suitable zone axis with respect to the resolving power of the microscope and the low thickness of the sample may introduce relaxation effects.

The observation of thickness fringes at inclined boundaries under weak beam conditions is much less stringent (lower resolving power, sample thickness and orientation…). The interpretation of the fringe profiles is performed here using a fitting procedure. Although several parameters are required to model the interface, the material and the experimental conditions, only rough estimates of the parameters are required to lead to a fast convergence of the algorithm and all of them can be more accurately deduced this way. A check for consistency is easily performed by repeating the analysis on different thickness areas or orientations.

The relative merits and drawbacks of both techniques will be discussed with reference to recent results obtained on PbTiO3 ferroelectric domain walls at room temperature and to observations under way at high temperature.

17. ELECTRON MICROSCOPY

P06.17.001 CAPSID STRUCTURE OF A GEMINIVIRUS, AS DETERMINED BY CRYO-ELECTRON MICROSCOPY. Lee Faulkner [1], Wei Zhang [2], Norm Olson [2], Timothy S. Baker [2], Margaret Boulton [3], Jeffrey Davies [3], Mavis Agbandje-McKenna [1] and Robert McKenna [1], [1] Department of Biological Sciences, University of Warwick, Gibbett Hill Road, Coventry CV4 7AL, UK, [2] Department of Biological Sciences, Purdue University, West Lafayette, Indiana 47907-1392, USA, [3] Department of Virus Research, John Innes Centre, Norwich Research Park, Colney, Norwich, Norfolk NR4 7UH, UK

We have used cryo-electron microscopy (cryo-EM) and three-dimensional image reconstruction methods to determine the structure of maize streak virus (MSV). The first structure of a geminate virus to be obtained. Using an amino acid sequence comparison alignment of the capsid proteins (CP) of satellite tobacco necrosis virus (STNV) (1) to that of MSV, made possible, the fitting of an atomic model of the MSV CP into the cryo-EM density map, to build a complete geminate capsid. The twinned quasi-isometric geminate particle is made up of 110 CP subunits (~28kD) arranged in 22 capsomeres and has a dimension of approximately 20-30nm. The CP has the usual viral jelly-roll made up of eight stranded b-barrels. The corners of the b-barrel strands have inserted residues compared to the STNV structure and this can explain the increase in size of the MSV capsid to that of STNV. The five CP subunits closest to the interface of the two particles have their helical N-terminal domains “flipped out” such that they form a-bridges between the two particles. The helical region of the CP has been identified as the DNA binding site (2).

P06.17.002 CRYO-ELECTRON MICROSCOPY OF GDP-TUBULIN RINGS. W.V. Nicholson [1], M. Lee [1], K.H. Downing [2], E. Nogales [1, 2], [1] MCB, UC at Berkeley, Berkeley, CA 94720, USA, [2] Life Sciences, LBNL, Berkeley, CA 94720, USA

Rings of GDP-tubulin formed in the presence of divalent cations have been studied using cryo-electron microscopy. The structure of such rings resembles that of depolymerizing microtubule ends and corresponds to an unconstrained conformation of tubulin in its GDP state. The use of cryo-techniques has allowed us to image the ring polymers free from dehydration and flattening artifacts. Preparations of frozen-hydrated GDP-tubulin rings are generally heterogeneous and contain a mixture of double, triple and incomplete rings, as well as spirals and some rare single rings. Images of different polymer types can be identified and classified into groups that are then amenable for averaging and single particle reconstruction methods. Identifying the differences in tubulin structure between straight and curve protofilaments will be important to understand the molecular basis of dynamic instability in microtubules. A 3D reconstruction obtained from cryo-EM of tubulin double rings will be described.

P06.17.003 THE 3-D STRUCTURE OF ALEUTIAN MINK DISEASE PARVOVIRUS: IMPLICATIONS FOR DISEASE PATHOGENICITY. Robert McKenna [1], Norman H. Olson, Paul R. Chipman, Timothy S. Baker [2], Tim .F. Booth [3], Jesper Christensen, Bent Aasted [4], James M. Fox, Marshall E. Bloom, James B. Wolfinbarger [5], Mavis Agbandje-McKenna [1], [1] Department of Biological Sciences, University of Warwick, Coventry CV4 7AL, UK, [2] Department of Biological Sciences, Purdue University, West Lafayette, Indiana 47907-1392, USA, [3] NERC Institute of Virology and Environmental Microbiology, Oxford, UK, [4] Lab. of Virology and Immunology, Dept. of Veterinary Microbiology, The Royal Veterinary and Agricultural University, Copenhagen, DK, [5] Lab. of Persistent Viral Diseases, NIAID, Hamilton, MT, USA

The three-dimensional structure of expressed VP2 capsids of Aleutian mink disease parvovirus, strain G (ADVG-VP2), has been determined to 22Å resolution with cryo-electron microscopy and image reconstruction techniques. A structure-based sequence alignment of the VP2 capsid protein of canine parvovirus (CPV) provided a means to construct an atomic model of the ADVG-VP2 capsid. The ADVG-VP2 reconstruction reveals a capsid structure of mean external radius of 128Å with several surface features similar to those found in human parvovirus B19 (B19), CPV, feline panleukopenia virus (FPV), and minute virus of mice (MVM). Dimple-like depressions occur at the icosahedral two-fold axes, canyon-like regions encircle the five-fold axes, and spike-like protrusions decorate the three-fold axes. These spikes are not present in B19, and they are more prominent in ADV compared to the other parvoviruses owing to the presence of loop insertions which create 'mounds' near the three-fold axes.

Cylindrical channels along the five-fold axes of CPV, FPV and MVM, which are surrounded by five, symmetry-related b-ribbons, are closed in ADVG-VP2 and B19. Immunoreactive peptides made from segments of the ADVG-VP2 capsid protein map to residues in the mound structures. In vitro tissue tropism and in vivo pathogenic properties of ADV map to residues at the three-fold axes and to the wall of the dimples.

P06.17.004 EFFECT OF MICROSTRUCTURAL EVOLUTION ON IMPACT FATIGUE OF COMPRESSOR VALVE STEEL Ping Liu, Guocai Chai and Sören Olsson, R & D Centre, AB Sandvik Steel, 811 81 Sandviken, Sweden

Conventional stainless steel used for compressor valve with a composition of 0.37 C-0.39Si-0.60 Mn-13.5 Cr-1.0 Mo-0.20 P-0.002 S (wt%) consists of martensites (α') and Cr-enriched $M_{23}C_6$ carbites as shown in Fig.1. A modification of the structure resulted in an improvement of the impact and bending fatigue. These were partly attributed to the increase of retained austenite from 2 to 10 vol %(1). For the improved steel the number of $M_{23}C_6$ (Fm3m; a=10.6 Å) particles is dramatically reduced as shown in Fig. 2. As a result the carbon activity in the matrix increased and the precipitation of small particles (<100nm) of Fe_3C (Pnma; a=5.0915 Å, b=6.7446 Å and c=4.5276 Å) took place as indicated in Fig.3 and Fig.4. It is well known that large particles reduce the fatigue life by both facilitating crack nucleation by slip band/particle interaction and increasing crack growth rates by interface decohesion and voiding within the plastic zone at the crack tip. Small particles, on the other hand, can have beneficial effects by homogenising the slip pattern and delaying fatigue-crack nucleation. Thus, the precipitation of small carbide particles may also contribute to the improvement of impact fatigue of the studied steel.

18. ELECTRON DIFFRACTION

P05.18.001 KIKUCHI ELECTRON DOUBLE DIFFRACTION. R.K. Karakhanyan and S.E. Bezirganyan, Department of Physics, Yere-van State University, #1, A. Manoogian St., Yerevan 375025, Armenia.

The purpose of the present work is to extend the phenomenon of the Electron Double Diffraction (EDD) to include the Kikuchi patterns. Kikuchi EDD means that once and twice diffracted electron beams as well as the primary electron beam can become sources of Kikuchi patterns, i.e. these diffracted beams are exposed to inelastic scattering process, which takes place for the primary electron beam [1]. The resulting Kikuchi pattern is a superposition of the primary pattern with the source in the incident beam and of secondary patterns with sources in once and twice diffracted beams. The single crystalline silicon films were used as specimens for investigations. Silicon Kikuchi transmission patterns were obtained when the incident beam is approximately parallel to [112], [110], [210], [310] and [111] axes.

Formation of forbidden and unindexed Kikuchi lines, enhancement of excess forbidden Kikuchi lines near spot reflexes with the same indices, mutual reversal contrast of excess and defect Kikuchi lines under passing of excess line near strong spot reflex with other indices, enhancement of excess line near spot reflex with other indices under passing of correspondent defect line near strong spot reflex are the direct consequence of Kikuchi EDD. It is shown [2,3], that under decrease of diffracted beams' intensity by means of crystal thickness, temperature, orientation variation and electron energy change all above mentioned manifestations of Kikuchi EDD grow weak, which confirms correctness of mechanism of their appearance proposed in present work.

P05.18.002 SIMULATION OF DIFFUSE SCATTERING FROM SHORT-RANGE-ORDERED Cu_3Au TYPE FACE-CENTRED CUBIC STRUCTURE. X. J. Jiang, J. K. Bording and J. Tafto, Centre for Materials Science/Department of Physics, University of Oslo, Gaustadalleen 21, N-0371 Oslo, Norway.

It is well known that in some binary alloys, such as Cu_3Au, small domains of the ordered structure are present, separated by antiphase domain boundaries. The antiphase domains give rise to characteristic short-range-order diffuse scattering in the diffraction patterns. Several antiphase configurations and corresponding diffuse scattering have been proposed in the literature [1,2].

We have performed computer simulation using Cu_3Au as an example. In a wider perspective we intend to approach the more complex system Al-Zn-Mg that exhibits similar diffuse scattering. The atomic arrangement and resulting short-range-order scattering of Cu_3Au were simulated for different cooling rates. Special attention was focused on the antiphase domain boundary types and the accompanying diffuse scattering. The results of the simulation are in good agreement with the experimental observations of split spots presented in the literature.

P05.18.003 STRUCTURE DETERMINATION OF METAL-RICH COMPOUNDS FROM SELECTED AREA ELECTRON DIFFRACTION. Th. E. Weirich, Mat. Science, Darmstadt Univ. of Technology, 64287 Darmstadt, Germany, X.D. Zou, S. Hovmöller, Structural Chemistry, Stockholm Univ., 10691 Stockholm, Sweden, A. Simon, Max-Planck-Inst. f. Festkörperforschung, 70506 Stuttgart, Germany, G. Cascarano, C. Giacovazzo, CNR-IRMEC Dip. Geomineralogico, Campus Univ. Via Orabona 4, 70125 Bari, Italy

Electron diffraction (ED) is due to the strong interaction of electrons with matter an excellent tool for studying the interior structure of small crystalline samples down to few nanometers in size. On the other hand the strong interaction gives rise to dynamical diffraction (multiple scattering) effects which often leads to diffracted intensities far away from the predicted by the kinematic theory. Although ED without any dynamical contribution can hardly be realised in practice, it is possible to find experimental conditions under which the dynamical effects can be kept at a low level. Such data can be treated in the first approximation as pseudo-kinematic, *i.e.* traditional strategies for solving crystal structures are expected to work. Here we show that quantified ED patterns can be used for solving crystal structures of non-light element compounds to high accuracy. Several known metal-rich structures M_xX_y (M = Ti, Zr; X = S, Se; $x > y$) were investigated in a 300 kV Philips CM30ST microscope. Selected area ED patterns were recorded from prominent zone axis - in this series always along a short 3.5 Å crystal axis - and processed by ELD [1] for extracting integrated intensities. These 2D data sets were fed into SIR97 [2] modified with electron scattering factors and the most probable E-maps were calculated. The trial structures proposed by SIR97 revealed in all cases the complete structures. The projected atom positions agreed on average within 0.2 Å with those from the X-ray determination on single crystals. The obtained results show that dynamical effects can be controlled in a standard ED experiment so that direct methods can be applied for solving crystal structures in a quasi-automatic manner.

P05.18.004 NEW METHOD OF ANALYSING ELECTRON DIFFRACTION DATA. U. Wilke and W. Mader Institut für Anorganische Chemie der Universität Bonn, Römerstrasse 164, 53117 Bonn, Germany

Structure determination of small and defected crystals is the domain of electron diffraction. We present an application of a microdiffraction technique to inorganic crystal structure refinement. Our method is based on the program package ELSTRU by Jansen et al. [1]. We use convergent beam diffraction patterns taken with a spot size of $\approx$ 8 nm. Intensities for various beam directions are given by the corresponding position within the diffraction discs. This allows to obtain up to nine data sets for one specimen thickness. The discs obtained should not overlap because the background intensity around each diffraction disc needs to be substracted which is perfomed by extrapolation. The intensities serve as input data for the program package ELSTRU. The method was tested on simulated [2] and on experimental diffraction patterns of corundum (α-Al_2O_3). The results calculated from different data sets of diffraction pattern (simulated as well as experimental) reproduced the same thickness and the known structural parameters. The different data sets corresponding to different directions of the incident beam yield shifts of the centers of Laue circles as expected. Experimental intensities are recorded on a 2k×2k CCD camera (Gatan Megascan) attached to a Philips CM300 UT FEG electron microscope.

19. NON-AMBIENT CONDITIONS

P08.19.003 PRESSURE INDUCED T_C AND STRUCTURAL VARIATIONS OF $PrBa_2Cu_3O_x$ SUPERCONDUCTOR. J. Ye and A. Matsushita, National Research Institute for Metals, 1-2-1 Sengen, Tsukuba, Ibaraki, Japan, and Z. Zou, Electrotechnical Laboratory, 1-1-4 Umezono, Tsukuba, Ibaraki 305, Japan

T_C and structural parameters of $PrBa_2Cu_3O_X$ were investigated as a function of pressure up to 10 GPa. The compound has been considered as an exceptional material to be non-superconductive among the $RBa_2Cu_3O_X$ (R = rare earth) compounds, since the discovery of the oxide high-T_C superconductors in 1986. Recently, however, superconducting $PrBa_2Cu_3O_X$ has been grown by travelling-solvent floating-zone method [1]. In order to clarify the origin of the superconductivity, we have studied pressure dependence of T_c of the compound by electrical resistance measurements using a cubic anvil apparatus under hydrostatic pressure up to 10 GPa [2]. A large positive pressure coefficient of T_C, dT_C/dP, with a maximum of 7.4 K/GPa, was observed. The results showed an opposite behaviour with those expected from the widely accepted "hybridization model", which was proposed to explain the non-superconductivity of $PrBa_2Cu_3O_X$. We have further carried out X-ray diffraction under pressure using a diamond anvil cell. The *a*-, *b*-, and *c*-lattice parameters were found to compressed linearly as a function of pressure. The linear compressibilities, -dln*a*/dP, -dln*b*/dP, and -dln*c*/dP, were evaluated to be $2.07x10^{-3}$, $1.71x10^{-3}$, and $3.76x10^{-3}$ GPa^{-1}, respectively. The details of the experiment and Rietveld structural refinement to the high pressure diffraction patterns will be reported. The distribution of carriers in $PrBa_2Cu_3O_X$ under high pressure will also be discussed.

P08.19.004 HIGH PRESSURE STUDIES OF VANADIUM DOPED Bi 2212 SYSTEM. Ravhi S Kumar, A.Sekar, N.Victor Jaya and S.Natarajan, Department of Physics , Anna University , Chennai 600 025 , INDIA.

The Bi based 2212 superconductors exhibit metal insulator transition when a rare earth is doped at the calcium site [1- 4]. By keeping the rare earth concentration at the calcium site invariant, doping of Pb at the Bi site also drives the system to exhibit the phenomena [5]. We have synthesised ($Bi_{1-x}V_x)_2 Sr_2 Ca_{0.7} Y_{0.3} Cu_2 0_{8+y}$ samples with nominal V concentrations (0.025, 0.05 and 0.1) as successful V doping has been reported in Bi 2212 [6] . High pressure resistivity and high pressure X ray diffraction studies were performed up to 15GPa employing a diamond anvil cell on the system for V concentration 0.025 for possible structural phase transitions. The results will be discussed in comparison with the high pressure reports available for other systems.

P08.19.005 HIGH-PRESSURE STRUCTURAL STUDIES OF STRONTIUM. T.Bovornratanaraks, D.R. Allan, R.J. Nelmes, M.I. McMahon and S.A. Belmonte Department of Physics and Astronomy, University of Edinburgh, JCMB, Kings' Building, Mayfield Road, Edinburgh, U.K. EH9 3JZ.

The alkali-earth metals Ca, Sr and Ba have a rich variety of high-pressure crystal structure and have stimulated a substantial number of experimental and theoretical studies of their transition mechanisms. In previous high-pressure energy dispersive powder diffraction studies of Sr[1,2], the following sequence has been reported: face-centred cubic to body-centred cubic at 3.5 GPa; to Sr-III with the orthorhombic structure *Imma* structure at 26 GPa; to a more complex Sr-IV at 35 GPa; and to the Sr-V phase at 40 GPa. We have embarked on a re-examination of the high-pressure structures and transitions using angle-dispersive powder diffraction techniques with the image-plate area detector on station 9.1 at SRS Daresbury Laboratory. We find the same sequence as has been previously reported up to Sr-III, but the two-dimensional data obtained from the image plate clearly shows that Sr-III has the tetragonal β-tin structure[3], and not an orthorhombic *Imma* structure as previously thought [2]. We have now obtained extensive data through the transition to Sr-IV and in the Sr-IV phase. The transition appears to involve an intermediate structure that has yet to be understood, but the structure of Sr-IV has been solved as a quite complex monoclinic structure. Pseudopotential calculations are now also in progress using the CASTEP code. The lastest results of both the diffraction studies and the calculations will be presented.

P08.19.006 ACCURATE STRUCTURE ANALYSES OF Cs HIGH PRESSURE PHASES USING SR UNDULATOR BEAM AT SPring-8. Y.Ohishi and O.Shimomura, SPring-8, Hyogo 679-5198, Japan, M.Takata, Dept. of Material Science, Shimane University, Matsue 690-8504, Japan, and E.Nishibori and M.Sakata, Dept. of Applied Physics, Nagoya University, Nagoya 464-8601, Japan

In the last two decades, the progress of accurate structure analyses using an advanced synchrotron radiation x-ray source can provide the electronic level structural studies in the field of high-pressure science. Cesium shows bcc-fcc(I)-fcc(II) phase transitions through 0~5 GPa. The theoretical study has suggested that the charge transfer causes these transitions from *s*- to *d*-orbital under high-pressure (*s*-*d* transition). Although the lattice constant change at bcc-fcc(I)-fcc(II) transition is clearly observed, the direct structural evidence of the *s*-*d* transition has never been experimentally obtained. If the *s*-*d* transition really exists, the electronic level structure analysis should enable one to observe

deformation of electron density due to *s-d* transition. The purpose of the this study is 1) to establish such an electronic level structure analysis under high pressure utilizing third generation undulator beam and 2) to examine the phase transitions of Cs by the established method.

In order to observe an electronic level structure, the essential importance is to collect an accurate x-ray diffraction data. In the present study, synchrotron powder data of Cs under high pressure is measured using the Diamond Anvil Cell (DAC) with a high energy, high brilliance and high efficiency beam emanating from the undulator at BL10XU in SPring-8. The charge density analysis is performed by the Maximum Entropy Method (MEM).

P08.19.009 MAGNETIC AND CRYST. STRUCT. OF THE LAVES HYDRIDES. INFLUENCE OF CHEMICAL SUBSTITUTION AND APPLIED PRESSURE. O.L. Makarova [1], I.N.Goncharenko [2], I.Mirebeau [3], A.V.Irodova [1], [1] RRC "Kurchatov Institute", [2] RRC "Kurchatov Institute", Laboratoire Leon Brillouin, CEA-CNRS CEA/Saclay, [3] Laboratoire Leon Brillouin, CEA-CNRS CEA/Saclay.

RMn_2 compounds (R=Y, rare earth) show very interesting features, namely frustration in the Mn magnetic sublattice and instability of the Mn magnetic moments. Mn magnetism, being close to limit of instability between localized and delocalised state, is very sensitive to the change of the interatomic distances. Hydrogen doping increases the lattice parameter (acting as "negative pressure") and stabilizes Mn magnetism. At the same time, we found a very unusual coupling between structural and magnetic properties in the hydrides. The magnetic R, Mn and structural H sublattices order simultaneously through a first order magneto-structural transition. We present a neutron diffraction study of the magnetic and crystal structures of the Laves hydrides $RMn_2D_{4.3}$ and $(R_xY_{1-x})Mn_2D_{4.3}$ (R= Tb, Dy, Ho) at ambient pressure and pressures up to 12 GPa. The combination of chemical substitution and applied pressure allow us to separate the effects of interatomic distances, hydrogen order, and dilutions in the magnetic sublattices.

The compounds $(R_xY_{1-x})Mn_2D_{4.3}$ (R=Er, Tm, Lu) and $(Ho_xSc_{1-x})Mn_2D_{4.3}$ show another interesting example of coupling between magnetic and structural properties. In this case, chemical substitution leads to a change in the crystal structure from the cubic C15 to the hexagonal C14. We have studied the intermediate defect structures with stacking faults. We got a very unusual result: the defect phases, having no long range structural order, show a long range magnetic order.

P08.19.010 HIGH PRESSURE STRUCTURAL STUDIES OF ICES AND ICE MIXTURES. J.S.Loveday, R.J.Nelmes and M.Guthrie, Department of Physics and Astronomy, The University of Edinburgh, Edinburgh EH9 3 JZ, United Kingdom, S.Klotz, J.M.Besson and G.Hamel, Université P et M Curie, Paris 75252, France, D.J.Francis, Rutherford Appleton Laboratory, Chilton, OX11 0QX, United Kingdom.

The high-pressure behaviour of ices (for example H_2O, NH_3 ,CH_4, H_2S) and ice mixtures provides fundamental information on the density dependence of interatomic potentials. In addition, since ices are the major component of the outer planets and their satellites, high-pressure properties underpin modelling of these bodies. Accurate structural information at high-pressure is vital to the understanding of high-pressure behaviour, and the development of the Paris-Edinburgh cell for neutron diffraction has made it possible to obtain accurate structural information over a wide range of pressures on H-containing systems.

Studies of the high-pressure structures of deuterium sulphide (D_2S) suggest increasing orientational order of the molecules and the onset of significant hydrogen bonding at high pressure. A detailed comparison of the structures of ices VII and VIII to 20 GPa has explored the pressure dependence of both the dynamics and the multi-site disordering of the oxygen sublattice in ice VII. Neutron diffraction studies of ammonia monohydrate - the first neutron study of a molecular mixture above 0.5 GPa - reveal an unexpectedly rich phase diagram and suggest remarkable structural complexity at high pressure. Similar structural complexity is also observed in the high-pressure phases of methane. Complexity is emerging as a common feature of the high-pressure structures of ices, in contrast to previous expectations of a general trend towards structural simplicity under increasing pressure.

P08.19.011 THE CRYSTAL STRUCTURES OF TWO HIGH-PRESSURE POLYMORPHS OF Ta_2O_5. M. Sundberg[1], I.P. Zibrov[2], V.P. Filonenko[3] and P.-E. Werner[1], [1]Department of Inorganic and Structural Chemistry, Arrhenius laboratory, Stockholm University, S-106 91 Stockholm, Sweden, and [2]Institute of Crystallography, Russian Academy of Sciences, 117333 Moscow, Russia, [3] Institute for High Pressure Physics, Russian Academy of Sciences, Troitsk, 142092 Moscow Region, Russia

The crystal structures of two high-pressure forms of Ta_2O_5, B-Ta_2O_5 and Z-Ta_2O_5, prepared at *P*=80 kbar, have been solved from X-ray powder diffraction data. The X-ray powder pattern taken from the Ta_2O_5 sample was very similar to the one recently taken from a two phase mixture of B-Nb_2O_5 and Z-Nb_2O_5 (1). The X-ray data thus indicated that the Ta_2O_5 phases were isostructural with the niobium oxides.

The unit cell dimensions are: *a*=12.785, *b*=4.853, *c*=5.527 Å and β=104.26° (B-Ta_2O_5) and *a*=5.225, *b*=4.699, *c*=5.853 and β=108.20° (Z-Ta_2O_5).

The final R-values from the Rietveld refinement of the two-phase sample are 0.026 (B-Ta_2O_5) and 0.032 (Z-Ta_2O_5). The tantalum atoms are six-coordinated in B-Ta_2O_5 and seven coordinated in Z-Ta_2O_5. A similar kind of seven-coordination as found for Z-Ta_2O_5 has been observed in the mineral baddeleyite ZrO_2 (2). B-Ta_2O_5 has previously been prepared by hydrothermal methods (3), while Z-Ta_2O_5 represents a new polymorph of Ta_2O_5.

High-resolution electron microscopy studies of the sample showed defects and intergrowth of the two phases. Structure models have been deduced. It is interesting to note that the electron microscopy results showed that due to the similarities in structures, it would not have been possible to deduce the unknown crystal structure of Z-Ta_2O_5 from the HREM images only.

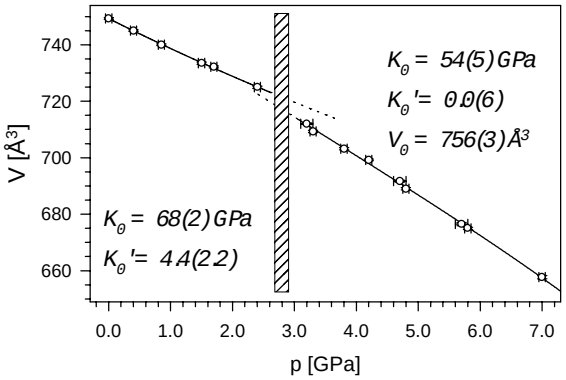
P08.19.012 COMPRESSIBILITY, PHASE TRANSITION AND STRUCTURE OF NOSEAN AT HIGH PRESSURE. H. Schulz, S. Werner, J. Wittlinger, Institut für Kristallographie und Angewandte Mineralogie, Universität München, Theresienstr. 41, D-80333 München, Germany.

The mineral nosean ($Na_8[Si_6Al_6O_{24}]SO_4$) crystallizes in the space group P23. The topology of the aluminosilicate framework is that of sodalite [1].

At a pressure of 2.8(4) GPa, nosean shows a phase transition as concluded from a discontinuity in the pressure dependence of the unit cell volume (Fig.).



Structure determinations at 0, 1.70(5) and 3.2(1) GPa revealed, that every second cage within the aluminosilicate framework is empty. Whereas the sulphate ion is disordered in the phase stable at ambient conditions, it adopts an ordered arrangement within the high pressure phase (space group R3). The symmetry reduction from cubic to trigonal allows separate compression mechanisms for the empty and filled cages.

At 7.6(1) GPa, a pressure induced amorphisation was observed.

P08.19.013 STRUCTURE ANALYSIS OF NON-MOLECULAR PHASE OF SnI_4 USING ANOMALOUS X-RAY SCATTERING AT HIGH PRESSURE. K. Sato and N. Hamaya, Graduate School of Humanities and Sciences, Ochanomizu University, Tokyo 112, Japan.

Molecular crystal SnI_4 exhibits novel phenomena such as metallization, amorphization, and molecular dissociation at high pressure. Our previous work demonstrated that SnI_4 showed the high-pressure structure sequence, first crystalline phase (CP-I ; insulator) - second crystalline phase (CP-II ; metallic) - amorphous state - third crystalline phase (CP-III). Diffraction patterns of CP-III measured above 61 GPa can be explained by the fcc lattice. A very small value of the nearest interatomic distance in CP-III is almost the same as that of non-molecular solid iodine, which indicates the dissociation of SnI_4 molecules. Three crystal structures can account for the observed fcc pattern; (1) phase separation into I_2 and amorphous Sn or amorphous SnI_2, (2) full disorder structure in which both iodine and tin ions are randomly located at the fcc sites, (3) partial disorder structure in which iodine ions are located at the ideal fcc sites and tin ions randomly occupy the interstitial sites. The purpose of this work is to clarify the atomic arrangement in CP-III of SnI_4 using x-ray anomalous dispersion effect near the K absorption edge of Sn.

We have carried out high-pressure powder x-ray diffraction measurements using synchrotron radiation at the SPring-8 (BL10XU). The radiation was monochromatized to an energy between 28.796 keV and 29.186 keV. The incident beam intensity was monitored continuously by a pin photodiode placed in front of a diamond anvil cell set at 63 GPa. Absorption coefficient of the sample was measured using another pin photodiode. Obtained intensities of reflections were found to decrease at energies very close to the absorption edge. Such an intensity variation is consistent with that expected from the full disorder structure model.

P08.19.014 STRUCTURES AND TRANSITIONS IN BARIUM ABOVE 12GPA: A SOLUTION FOR Ba-IV. R.J. Nelmes, M.I. McMahon, S.A. Belmonte and D.R. Allan, Department of Physics and Astronomy, The University of Edinburgh, Edinburgh EH9 3JZ, UK.

Barium is known to transform at 12.6GPa from an hcp phase to phase IV. The structure of this phase has eluded several attempts at solution [1]. The powder patterns are strongly textured and the structure is evidently quite complex [1]. We have collected image-plate diffraction data on station 9.1 at SRS Daresbury. These show that a gradual increase in pressure through the transition region over several hours leads to the formation of quite large crystallites, and 2-d patterns displaying strong diffuse scattering. In some cases, it has proved possible to obtain a small number of crystallites – just one in one case – which has allowed the collection of single-crystal data, both with the image plate and on a laboratory-source 4-circle diffractometer. It appears that there is an intermediate phase and that the structures of it and phase IV are of an unusual and complex kind, including a disordered component. These structures have been determined and refined from both the powder and the single-crystal data. Full details will be presented.

P08.19.015 HIGH-PRESSURE STRUCTURE VARIATION OF SPIN-PEIERLS CRYSTAL $CuGeO_3$. T.Yamanaka, A. Yoshiasa, T. Nagai, G. Yagyu Dept. Earth and Space Sci. Graduate School of Sci. Osaka Univ. 1-1 Machikaneyama Toyonaka Osaka 560-0043 Japan

$CuGeO_3$ characterized by spin-Peierls transition has several polymorphic transitions under the conditions of different hydrostaticity. Pressure-induced phase transition of $CuGeO_3$ has been elucidated using diamond anvil together with synchrotron radiation in order to comprehend the magnetic spin-lattice interaction under the condition of compression. Structure change of Phase I with pressure Phase I stable at ambient condition (Pbmm a=0.481nm, b=0.847nm, c=0.294nm) has an einer tetrahedral chain structure of GeO_4. CuO_6 octahedra link each other by shared edge in the direction of parallel to c axis. The octahedra is deformed by Jahn-Teller effect. Single crystal structure analyses at 2.93GPa, 3.90GPa and 5.3GPa reveal the rotation of octahedra and more deformation of octahedron to produced a dimarization. Jahn-Teller effect on Cu-O bond becomes less obvious with pressure. Volume of CuO6 is noticably compressed, while GeO_4 tetrahedron little changes. Hydrostaticity of compression brings different bulk modulus (Ko) of 47.1GPa under hydrostatic and 85GPa under nonhydrostatic condition. Structure determination of Phase IIUnder hydrostatic compression Phase I is reversibly transformed to a high pressure form (Phase II) at 6.3GPa. Despite the noticeable shrinkage of b axis and a little elongation of a axis of Phase I, this first-order transition is reversible. Consequetty in situ intensity measurement is required for the structure analysis. The structure of Phase II ($P2_1/c$ a=0.4935(57)nm, b=0.6754(7)nm, c=0.6208(11)nm β = 92.668(29)° has been clarified by single crystal structure analysis. Diffraction intensities were collected at 6.4GPa by using DAC with hydrostatic pressure media of methanol-ethanol mixture. Striking features are (1) germanium ion changes its coordination number to 5-fold (GeO_5), (2) copper ion occupies a position of 7-folded sites (CuO_7) and (3) these changes are caused by the martensic transition. Phase III and Phase IV under nonhydrostatic pressure Nonhydrostatic compression without pressure media brings Phase III (blue) at 7.5GPa and furthermore to Phase IV (green) at 9.5GPa. These structure transitions are brought about by the stress. At decompression, Phase Ireversibly changes to Phase III at 5GPa and the latter remains its structure at room pressure (Jayaraman et al., 1995). Phase III has an irreversible and then it is quenchable. The crystal structures of the both high pressure forms are still unknown. The nonhydrostatic stress produces various phases which are mostly irreversible and some indicate a monotropic path.

P08.19.016 HIGH PRESSURE STUDIES OF NbO_2F. S. Carlson, ESRF, B.P. 220, F-38043 Grenoble Cedex, France, and A.-K. Larsson and F. Rohrer, Inorganic Chemistry Dept., Stockholm University, S-10941 Stockholm, Sweden.

High pressure *X*-ray powder diffraction studies of NbO_2F, in the pressure range from ambient to 31 GPa, have been performed at the high pressure beamline ID30, ESRF.

The investigations were made with a membrane driven diamond anvil cell (diamond tip diameter 0.3 mm, and gasket hole diameter 0.125 mm). Pressure medium was silicon oil, and the pressure was monitored with the ruby fluorescence method. The *X*-ray radiation (0.4246 Å) from two phased undulators, reduced down to a beam spot size of 0.09x0.09 mm^2, was used.

Preliminary results show that the cubic ReO_3-type structure (space group: *Pm*-3*m*) of NbO_2F undergoes several pressure induced phase transitions in the investigated pressure range. At 9.2 GPa, the structure has transformed to the hexagonal symmetry, and Rietveld refinements indicate that it is of the VF_3-type (space group: *R*-3*c*). Over ~20 GPa, the diffraction patterns indicate that NbO_2F transforms back to cubic symmetry, but display also marked signs of amorphization with the disappearance of diffraction peaks at higher angles.

P08.19.018 IN-SITU HIGH PRESSURE X-RAY DIFFRACTION STUDY ON $CuGeO_3$. S. R. Shieh, H. K. Mao, R. J. Hemley, A. Jayaraman, Geophysical Lab and Center for High Pressure Research, Carnegie Institution of Washington

The discovery of spin-Peierls transition on $CuGeO_3$ at 14 K and ambient pressure has attracted lots of attention. Recently Raman spectroscopy and energy dispersive X-ray studies show that $CuGeO_3$ has encountered a phase transition near 7 GPa when pressure medium is strictly hydrostatic. However, the new high pressure phase has been assigned as either monoclinic (Adams et al. 1991) or orthorhombic (Jayaraman et al. 1997 and Ming et al. 1998). An attemp has been made to use the high resolution angular dispersive X-ray diffraction method to determine the high pressure structure of $CuGeO_3$ at pressure above 7 GPa.

In this study, the ungrinded $CuGeO_3$ powder was loaded in a Mao-Bell type diamond anvil cell with either He or 4:1 mixture of methanol/ethanol as pressure medium. Pressure was determined by the ruby fluorescence method. The sample was examined in angular dispersive X-ray diffraction using synchrotron radiation source with wavelength l =0.4956 angstron at Cornell High Energy Synchrotron Source (CHESS). Two phase transitions were observed when pressure was compressed up to 26 GPa. The first phase transition takes place at about 7 GPa, the other phase transition occurs at about 18 GPa. The detail structural information will be provided in this paper.

P08.19.019 ON THE PRESSURE-INDUCED CRYST-ALLINE-TO-AMORPHOUS TRANSITION IN BISMUTH OXIDE. S. Desgreniers S. Pilod, and C. Chouinard. Department of Physics and Ottawa-Carleton Institute of Physics, University of Ottawa, 150 Louis Pasteur, Ottawa, Ontario, Canada. K1N 6N5.

A crystalline-to-amorphous transition has been observed in pressure-densified bismuth oxide, starting the monoclinic α-phase. The onset of the transition to the amorphous state is at around 15 GPa and the disordered state is retained as the pressure is released from above 25 GPa to room pressure. From the X-ray structure factors, obtained by energy-dispersive and angle-dispersive X-ray diffraction and corrected for incoherent scattering, the average radial pair distribution function of the amorphous phase are extracted as a function of pressure. It is found that the Bi-Bi nearest neighbors distance in the disordered state changes by 7 % following a compression to 25 GPa. We also report on the Raman spectroscopic evidence for the crystalline-to-amorphous transition.

P08.19.020 MODELLING TRANSFORMATIONS OF HYDROGEN-BONDED STRUCTURES AT HIGH PRESSURES. Andrzej Katrusiak, Department of Crystal Chemistry, Adam Mickiewicz University, Grunwaldzka 6, 60-780 Poznan, Poland

Hydrogen bonds have much lower energy than covalent bonds binding atoms into molecules, or than electrostatic interactions in ionic crystals. Thus, like van der Waals interactions, the hydrogen bonds are prone to transformations when a substance changes its thermodynamic conditions. At the same time, because the hydrogen bonds are relatively weak, their transformations are often blurred by other effects in a transforming structure. Therefore it is important to understand and to be able to model the response of the hydrogen bonds to elevated pressures. Such models would be helpful for predicting the properties of hydrogen-bonded structures in the function of temperature and pressure, for example of pressure-preserved food, of high-pressure polymorphs of ices, or of hydrogen-bonded ferroelectric crystals. Of the immense variety of types of hydrogen bonds we chose bonds OH- -O, NH- -N and NH- -O for our initial studies. They are relatively strong and most abandoned in Nature. A simple model of the OH- -O bond transformations affords a straightforward explanation of the coupling between atomic displacements and H-disordering, of the occurrence of tricritical points in ferroelectric crystals, anomalies in thermal expansion, and gives the quantitative temperature function of their phase-transition temperatures [1-3]. Most recently we investigated the stability of protons in NH- -N bonds [4], and found a new group of NH- -N bonded ferroelectrics [5].

P08.19.021 ON THE ORIGIN OF 'DEBYE-SCHERRER ELLIPSES' FROM 3-D FULLERENE POLYMERS. L.Marques, Dept. Física, Universidade de Aveiro, 3800 Aveiro, Portugal. M.Mezouar, E. S. R. F., 38041 Grenoble, France. J-L.Hodeau, Laboratoire de Cristallographie, C.N.R.S., BP166 Cedex 09, 38000 Grenoble, France. M.Núñez-Regueiro, C.R.T.B.T., C.N.R.S., BP166 Cedex 09, 38000 Grenoble, France. N.R.Serebryanaya and V.A.Ivdenko, Inst. of Spectrosc. RAS, Troitsk Moscow Region, 142092 Russia. and V.D.Blank and G.A.Dubitsky, Res. Cent. Superhard Materials, 7-a Centralnaya Str., Troisk Moscow Region 142092 Russia.

High pressure studies have up to now determined the existence of 1-D and 2-D polymer fullerene structures. Synchrotron radiation powder diffraction measurements using a 2D fast scan detector were performed on C_{60} samples quenched from 13GPa and 820K. The analysis of all the reciprocal spectra indicates that the sample is a 3-D polymerized fullerite. For the same bulk sample, the observed elliptical shape of the Debye-Scherrer rings varies, depending on the orientation of the sample with respect to the incident beam, and can reach nearly perfect circles. These fullerene samples have been produced under uniaxial compression conditions and therefore we must conclude that the stress gradient, under which they were made, remain recorded in the quenched samples via a lattice deformation. This observed permanent anisotropic deformation is due to an irreversible change in the intermolecular bonding during the phase transformation. Structural models for the 3D C_{60} polymer will be presented.

P08.19.022 EXPERIMENTAL AND COMPUTATIONAL STUDIES OF InSb-IV. M.I. McMahon, G.J. Ackland and R.J. Nelmes, Department of Physics and Astronomy. The University of Edinburgh, Edinburgh EH9 3JZ, UK.

The high-pressure structures and phase diagram of InSb continue to attract considerable attention. Recent room-temperature imaging-plate studies [1], and high-temperature energy-dispersive studies [2], have revealed a phase diagram very different from that constructed in the 1960's. Below 8GPa and 300°C, the dominant form of InSb is InSb-IV, or the P4 phase, the structure of which is a surprisingly complex superstructure of that proposed initially in 1978 [1,3]. Although the P4 structure does have the same spacegroup (Cmcm) as the high-pressure phase of several other III-V and II-VI semiconductors, the superstructure nature of P4 remains, as yet, unique to InSb.

In this paper we review the most recent phase diagram of InSb, and present results from ab-initio pseudo-potential calculations aimed at understanding the reasons for the structural complexity of InSb-IV. The calculations confirm the superstructure to have a lower energy than the simpler Cmcm structure observed in other III-V and II-VI systems, and verify the nature of the atomic ordering.

P08.19.023 X-RAY DIFFRACTION STUDY OF DILUTE MAGNETIC SEMICONDUCTORS (DMS) UNDER HIGH PRESSURE PART I: $Zn_xCo_{1-x}S$. D. Gómez, Grupo de Cristalografía Dpto de Química, Facultad de Ciencias. Universidad de Los Andes Mérida, Venezuela. T. Tinoco, S. A. López. Lab. de Física Aplicada, Dpto de Física, Facultad de Ciencias, Universidad de Los Andes,Mérida, Venezuela. A. Polian and J.P. Itié. Physique des Milieux Condensés, Université Pierre et Marie Curie, B 77, 4, Place Jussieu, Paris-France.

Dilute magnetic semiconductors (DMS) constitute a class of semiconducting materials formed by randomly substituting a fraction of cations (in the II-VI or III-V compounds) by magnetic ions X(X= V, Cr, Mn, Co or Ni). These alloys exhibit a variety of novel magneto-optical properties coming from the exchange interaction between the magnetic ions and the conduction or valence electrons (s-p exchange interaction). This interaction is increased at high pressure and may induce phase transitions. In this work, $Zn_{0.9}Co_{0.1}S$ has been studied under high pressure up to 28 GPa. At high pressure the most intense peaks of the blende phase have been observed up to 17 GPa, but new peaks appear above 12,7 GPa. The new peaks have been indexed in a disordered rock-salt phase. This phase is stable at least up to 28 Gpa (maximum pressure reached in this experiment) The unit cell volume has been fitted with a firstorder Murnaghan equation of state. This deduced bulk moduli are B = (84 2) GPa in the zinc blende phase and B = (119 16) GPa in the NaCl phase, with B' = 4 in both cases. The recovered phase is identical to the initial phase at 0 GPa.

The samples used were prepared by chemical transport with nominal cobalt concentration x=0.1 The present experiments were conducted in a diamond anvil cell. Stainless-steel gaskets were used to confine the samples. The pressure-transmitting medium was silicon oil and the pressure was measured using the linear ruby fluorescence scale. EDX experiments were performed at the DW11 station on the wiggler line of the LURE synchrotron facility (Orsay, France) using the DCI storage ring.

P08.19.024 PHASE TRANSITION IN $CaCuGe_2O_6$. M. Tovar and W. Eysel, Mineralogisches Institut, University of Heidelberg, Germany

The compound $CaCuGe_2O_6$ [1] exhibits at room temperature a distorted pyroxen structure ($P2_1/c$) [2]. With increasing temperatures a sluggish phase transition between two monoclinic pyroxen-like forms $P2_1/c \rightarrow P2_1/n$ occurs [3]. High temperature X-ray powder investigations were performed by means of a Siemens powder diffractometer D500 (Ge primary monochroma-tor, $CuK\alpha_1$) with a high temperature device Buehler HDK 2.3 (platinum strip as sample holder and heater).

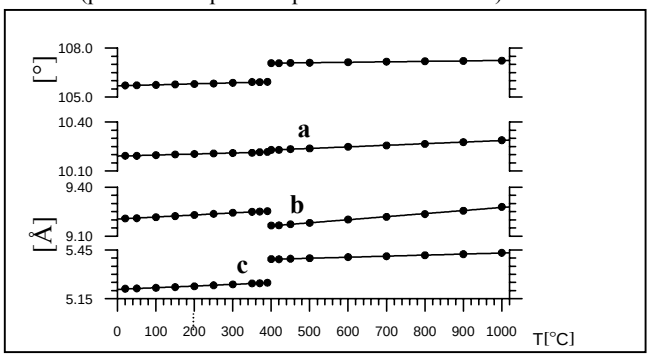

Fig. 1: Lattice parameters of $CaCuGe_2O_6$ from 20° to 1000°C

Applying whole powder pattern fitting the lattice parameters were determined from room temperature up to 1000°C in varying temperature intervals (Fig. 1). These measurements reveal the phase transition at 400°C. In both phases the lattice parameters change linearly. Together with previous DTA results the jump in the lattice parameters indicates a first order transition. High temperature Rietveld refinements are in progress.

P09.19.001 X-RAY DIFFRACTION UNDER NON-HYDROSTATIC CONDITIONS. L. Dubrovinsky, N. Dubrovinskaia, S. Saxena Department of Earth Sciences, Uppsala University

The stress state in a solid specimen compressed between two flat and parallel anvil faces (in a diamond anvil cell (DAC), for example) is nonhydrostatic. The resulting lattice strains measured by X-ray diffraction exhibit certain features which are absent if truly hydrostatic conditions prevails. We analysed the influence of deviotoric stresses on the behaviour of the samples in DAC from a point of view of nonhydrostatic thermodynamics. Such phenomena as recrystallization and preferred orientation, changing the pressure and temperature parameters of phase transitions and chemical reactions under stress could be quantitatively described. Application of the theory is demonstrated on an example of a study of wustite FeO at pressure up to 16 GPa. We found that pressure of phase transition is proportional to the uniaxial stress component and rises from 10.1 GPa for compression without pressure medium to the 15.4 GPa in Ar pressure medium. Extrapolation to zero stress conditions gives the value 16.8 GPa. This value is in good agreement with data by Fei (1996) (powder diffraction data, compression in He pressure medium, Ptr= 17(1) GPa) and Shu et al. (1998) (single crystal diffraction data, compression in He pressure medium, Ptr= 18(1) GPa).

Recently, a method to estimate single-crystal elastic moduli from polycrystalline X-ray diffraction of non-hydrostatically compressed material has been introduced (Singh, 1993; Singh and Balasingh, 1994; Singh et al., 1998). The method of analysis of lattice strain in non-hydrostatic stress states (NSS) is

based on transformation of the stress axis into crystal axis and further on calculations of the strain for given direction (diffracting plane normal) from elastic moduli (Singh, 1993; Singh and Balasingh, 1994; Uchida et al., 1996; Singh et al., 1998). It was assumed that the stresses for all crystallites with common direction of diffracted plane normal, could be averaged out (if crystallites are randomly oriented) (Singh, 1993; Singh and Balasingh, 1994; Uchida et al., 1996; Singh et al., 1998). But if the load direction is fixed, stresses transformed to crystal axis, depend on the orientation of the crystal and produce different strains. We propose the algorithm for calculating the shape of the diffraction lines from the non-hydrostatically compressed solid and apply it to study CsI and Pt at high pressures and temperatures.

P09.19.002 MICRO: A NEUTRON DIFFRACTOMETER, SPECIALIZED FOR HIGH PRESSURE MAGNETIC STUDIES. Goncharenko I.N. [1], Mirebeau I. [2], Gabriel A. [3], Molina P. [4], Böni P. [5], [1] Laboratoire Leon Brillouin, CEA Saclay, 91191 Gif-sur-Yvette, France and Russian Research Center "Kurchatov Institute", [2] Laboratoire Leon Brillouin, CEA Saclay, 91191 Gif-sur-Yvette, France, [3] European Molecular Biological Laboratory, 38043, Grenoble, France, [4] Ecole Centrale de Nantes, 1 rue de la Noé, 44000 Nantes, France, [5] Laboratoire for Neutron Scattering ETH&PSI, CH-5232 Villigen PSI, Switzerland

Starting from 1992, a project for neutron diffraction under very high pressures (up to 40- 50 GPa) is under development in the Laboratoire Léon Brillouin (Saclay), in collaboration with Kurchatov Institute (Moscow). The important part of the project is a new powder diffractometer MICRO (modified version of the spectrometer G6.1), specialized for high pressure studies of small samples in diamond or sapphire anvil cells. The diffractometer is located on a cold neutron guide of the ORPHEE reactor and operates with a long wavelength, very suitable for studies of magnetic or medium-scale structures. Focusing systems (made from Ni-Ti supermirrors) allow us to increase the flux at the sample place by one order of magnitude, whereas special environments reduce background down to a very low level (a few counts/per channel/ per hour). The allowed temperature range is from 1.5 to 300 K, the pressure range could vary from 0 - 8 GPa to 0 - 50 GPa depending on the values of magnetic moments and the complexity of crystal and magnetic structures.

The diffractometer is operating in the high pressure mode for about 150 days per year and is open for research proposals from external groups. This year we expect a new important step in the development of the MICRO diffractometer. A new multidetector, based on the delay line technique, is now under construction in the European Molecular Biological Laboratory (Grenoble). The multidetector, covering a higher solid angle, is expected to increase luminosity by another factor of 5.

P09.19.003 TEXTURE AS AN AID TO INDEXING AND STRUCTURE SOLUTION IN POWDER DIFFRACTION. Scott A. Belmonte and Richard J. Nelmes, Department of Physics and Astronomy, The University of Edinburgh, Mayfield Road, Edinburgh, EH9 3JZ, U.K.

The presence of texture in a sample is generally regarded as a hindrance when trying to determine a crystal structure from powder diffraction data. However, if handled correctly, there is potentially a wealth of additional information available from a textured sample, over a non-textured sample, which can possibly **aid** the structure determination process.

In a textured powder sample, the relative intensities of the diffraction peaks depend not only on the arrangement of atoms in the unit-cell, but also on the orientation of the sample with respect to the incident beam. The manner in which the intensities vary as the sample orientation is changed depends on the orientation distribution of the crystallites in the sample **and** the magnitude and direction - with respect to the unit-cell axes - of the reciprocal lattice vectors that contribute to each reflection. By collecting diffraction patterns from a textured sample in many different orientations and fitting the observed changes in intensity it is possible, in principle, to use the (hkl)-dependence of the variations to obtain reciprocal lattice vectors and thus index the powder pattern.

A description of texture and how it can be used to index a powder pattern will be given. It will also be shown how, once the correct unit-cell is known, texture can make it possible to extract relative intensities from exactly overlapping reflections thus helping structure solution. Examples of the successful application of these techniques to actual data collected from highly textured samples will be presented.

P09.19.004 CORRECTION OF DIFFRACTION OPTICS AND P-V-T DATA USING MULTIPLE THERMOELASTIC EQUATIONS OF STATE. Yusheng Zhao, Robert B. Von Dreele [1], Donald J. Weidner [2], [1] LANSCE, Los Alamos National Laboratory, Los Alamos, NM 87545, U.S.A, [2] CHiPR and Mineral Physics Institute, University at Stony Brook, NY 11794, U.S.A

The necessity of P-V-T data correction is vital in case of misalignment in diffraction optics and/or failure of thermocouple. This paper discusses how to correct the observed P-V-T data and diffraction optics from a diffraction spectrum using thermoelastic equations of state (EOS) of multiple phases. The unit cell volumes of multiple phases (derived from the same diffraction pattern) can be used to derive the experimental P-T conditions when the thermoelastic EOS of the multiple phases are well established and sufficiently different. The large intersection angle of isochoric lines of these phases in P-T space ensures the determination of P-T with satisfactory precision. Apparently, this method is very helpful when thermocouples fail in the experiment. On the other hand, severe “strain-shift” problem can be caused by the displacement of diffraction center as pressure and/or temperature changes. The strain-shift is calculated to be: $\delta(d/d) = \delta(2\Theta) \times \cot(\Theta)$, where $\delta(2\Theta) = (\text{dis.}/L)$, and dis. is the displacement of the diffraction center along the incident beam (Θ=180) direction and L is the distance of the diffraction center to detector. For the high P-T neutron diffraction experiment, such strain-shift problem becomes very serious when using a ceramic gasket for simultaneous high pressure and temperature experiment, where the hydraulic ram movement (roughly about twice of the dis.) is significant, especially at the initial compression stage. The consequence of the strain-shift is an apparent over-compression of the unit cell dimension and thus an overestimate of the pressure. This problem can be solved simply by monitoring the movement of the diffraction center and mechanically adjust of the press so as to restore the correct diffraction optics as calibrated at ambient conditions. As an intellectual exercise and also for the practical necessity, we have worked out a method to correct the strain-shift using the known thermoelastic equations of state of multiple phases. This approach assumes that all the multiple phases in the sample mixture experience the same pressure and temperature in the diffraction volume. The analytical solution of pressure, temperature, and volume can be derived by simple algebra. In real practice, the iso_(P,T) condition can be achieved readily via numerical computation by step-iteration of the strain-shift. The uncertainty of the P-V-T determination is inversely correlated to the precision of the diffraction refinement as well as to the contrast of thermoelastic parameters of the pressure standards. The experimental uncertainties of the P-V-T data related to the sample mixture method of the multiple phases are also discussed.

P11.19.001 THE ANISOTROPY OF STRUCTURAL DISTORTION OF Co^{III}-NITROAMMINES AT HIGH PRESSURE. E.V. Boldyreva and D.Y. Naumov, Institute of Solid State Chemistry and Mechanochemistry SB RAS, Kutateladze, 18, Novosibirsk, 128, 630128 Russia, email elena@solid.nsk.su, and H. Ahsbahs, Institute of Mineralogy of Marburg University, Hans-Meerwein Strasse, 35043 Germany.

Hydrogen bonds were shown to play a major role in the anisotropy of structural distortion of Co^{III}-nitropentaammine coordination compounds on cooling [1]. In the present contribution we report on the role of hydrogen bonds in the anisotropy of structural distortion of the same compounds induced by another isotropic action - hydrostatic high pressure - which was shown to be qualitatively different from that on cooling [2]. Single-crystal X-ray diffraction in the diamond anvil cell was used to follow the changes in lattice parameters with increasing pressure up to 5.0 GPa and to refine crystal structures at several pressures. The changes in the intra- and intermolecular distances and angles were followed. The compressibility of NH...O and NH...Cl hydrogen bonds was measured. The role of these hydrogen bonds in the anisotropy of pressure-induced structural distortion is discussed. It is compared with the role of hydrogen bonds in the distortion of the same structures on cooling and during homogeneous linkage isomerization [3]. The data from diffraction experiments are correlated with the results of high-pressure IR-spectroscopy [4].

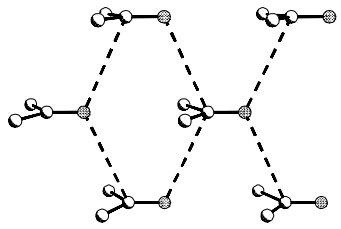
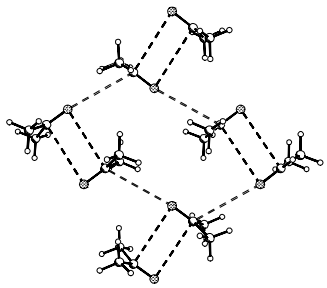
P11.19.004 THE INFLUENCE OF TEMPERATURE AND PRESSURE ON ACETONE. S. Parsons and C.R. Pulham, Department of Chemistry, The University of Edinburgh, Edinburgh, EH9 3JJ, D.R. Allan, Department of Physics and Astronomy, The University of Edinburgh, Edinburgh, EH9 3JZ, S.J. Clark, Department of Physics, The University of Durham, Durham, DH1 3LE, R.M. Ibberson, ISIS Facility, Rutherford Appleton Laboratory, Chilton, Didcot, OX11 OQX and L. Sawyer, Institute of Cell and Molecular Biology, The University of Edinburgh, EH9 3JR.



At high pressure (15 kBar) acetone forms layers in which each molecule is involved in four C..O contacts formed in a sheared-parallel motif. Although this structure is metastable at low temperature (165 K), the preferred structure at low temperature consists of layers in which pairs of acetone molecules interact in an antiparallel fashion, with each pair forming C..O contacts perpendicular to the planes of the molecules forming neighbouring pairs. Frozen acetone exhibits an unusual change in its heat capacity at around 130 K, although the nature of this transition has remained a mystery since it was first identified in 1929. Neutron powder-diffraction measure-ments at 5 K and a variable temperature X-ray diffraction study enable us to suggest that this is ascribable to strengthened C..O and CH..O contacts.

P11.19.007 HIGH-TEMPERATURE X-RAY DIFFRACTION STUDY OF Al-Ni-Cr INTERMETALLIC COMPOUND ALLOYED WITH VANADIUM AND TITANIUM. S.A.Petrova, R.G.Zakarov, V.L.Zyazev, and N.A.Vatolin, Institute of Metallurgy, Urals' Division, Russian Academy of Science, Ekatherinburg, 620 016, Russia.

Ternary Al-Ni-Cr intermetallic compound alloyed with vanadium and titanium were investigated using an automated diffractometer DRON-UM1 ($Cu_{K\alpha}$-radiation, pyrographite monochromator). Crystal structure of the main phase (85%) was defined to be of Al_3Ni_2 structural type, P-3m1 space group (PSC: hP5). X-ray phase analysis of the samples after DTA revealed an oxidation of the non-alloyed compound (a = 4.044(1) Å, c = 4.897(1) Å, F20 = 79 (.012, 21)); no oxidation of the compound alloyed with vanadium (a = 4.048(1) Å, c = 4.900(1) Å, F20 = 65 (.013, 24)) and titanium(a = 4.047(1) Å, c = 4.899(1) Å, F20 = 95 (.008, 26)) was observed by X-rays. With the use of the UVD-2000 attachment a high-temperature X-ray investigation of the above-mentioned alloys was carried out in the temperature range of 25-1350°C *in situ* in helium atmosphere. According to the results obtained temperature dependencies of crystal lattice parameters for phases available and coefficients of thermal expansion along *a* and *c* axes have been detected. It was found a structural transition of the initial phase with Al_3Ni_2 structure to the phase with AlNi-type structure (PSC: cP2) nearby 1000°C.



This work is supported by the Russian Foundation for Fundamental Research (grand N 98-03-32655).

P11.19.009 LOW TEMPERATURE CRYSTAL GROWTH & MULTIPLE TEMPERATURE STRUCTURAL STUDY OF $Cu(H_2PO_2)_2$ & ITS COMPLEXES. D.Y. Naumov and E.V. Boldyreva, Institute of Solid State Chemistry and Mechanochemistry SB RAS, Kutateladze, 18, Novosibirsk, 128, 630128 Russia, email d.y.naumov@iname.com, and D.S. Yufit and J.A.K. Howard, Chemistry Department, University of Durham, Durham DH1 3LE, UK.

Copper hypophosphite $Cu(H_2PO_2)_2$ and its complexes find important applications in the advanced technologies. Solid-state decomposition of these compounds gives at the initial stages latent copper centers with unusual chemical properties and increased catalytic activity, and can therefore be used as the basis of a number of new cheaper and cleaner technologies, including recording and storing information using non-silver photographic materials, metallization of dielectrics, manufacturing of printed forms in polygraphy [1].

Although they were needed for understanding the mechanism of the decomposition and for optimizing the technologies, molecular and crystal structures of these compounds remained unknown, since the compounds are highly unstable, low temperatures are required for crystal growth, low temperatures and rapid data collection - for a structural study.

The present contribution describes the results obtained with a Oxford Cryosystems Cryostream cooling device applied both for crystal growth and for data collection. Three polymorphs of copper hypophosphite and its urea complex were grown and studied with a Siemens SMART CCD area detector (down to 100K) and a Huber 4-circle diffractometer with a Siemens rotating anode generator with a Displex LT-unit (15K). The variable temperature data collection made it possible to study hydrogen bonds in the crystals and to discuss their possible role in solid-state reactivity.

P11.19.010 STRUCTURAL CHANGES OF TITANIUM UNDER ELECTRO THERMAL TREATMENT IN LIQUID NITROGEN ENVIRONMENT. I.S.Braude, F.F.Lavrentev, V.N.Nikiforenko, O.P.Salita, B.Verkin Institute for Low temperature Physics and Engineering, Ukraine Nat. Acad. of Sci., Kharkov 310164, Ukraine

Effect of electrical heating by current of $5x10^5$ A/cm^2 density in liquid nitrogen on titanium structure has been studied. The research is carried out on commercial Ti (BT-1.0) with initial grain size 6 mkm. The applied experimental methods are X-ray, resistometric and metallographic technics. The rolled specimens put into the bath with liquid nitrogen and current in impulse regime passed through them. X-ray phase determination has revealed the formation of new phase rutile TiO_2 simultaneously with grain size increase (by factor of about 3). The latter observation was supported by metallographic measurements. The rutile formation was explained by activation of oxygen diffusion from liquid nitrogen under heating by current. The grain size increased with collective recrystallization. Resistometric measurements favored with the view that electro thermal treatment facilitated higher mobility of oxygen and the role of the latter in the structure changes was a basic one. The role of the other defects of titanium crystal in the structure evolution after electro thermal treatment is discussed.

P11.19.011 A SCHEME FOR UNIQUELY LABELING POLYMORPHIC PHASES. Reuben Rudman, Chemistry Department, Adelphi University, Garden City, NY 11530, USA.

The nomenclature used for identifying polymorphic crystalline phases is inconsistent. Roman numerals, Greek letters, and, occasionally, Arabic numerals have all been used; the sequence of symbols may follow the historical order of the discovery of the phases, or it may start with the room-temperature phase or the phase formed from the melt or the low-temperature phase. Usually once a particular phase has been labeled and referred to in the literature, any new phases that are discovered subsequently are given their own unique labels. The reason for this is obvious. If the same symbol is used for different phases, unique identification of the phase in the literature will be difficult and retrieval from subsequent databases will be impaired. Unfortunately, in some cases the authors have relabeled all the phases, so that the literature now contains two different phases with the same label. This is singularly unfortunate, especially, in cases where the purported new phase is later shown not to exist. Other authors have commented on this problem too. For example, van Eijck et al. [Acta Cryst. (1998) B**54**, 291], in discussing the pressure-induced polymorphs of benzene, state: We deplore the practice of renaming known modifications, which is bound to lead to confusion sooner or later.

It is proposed here to uniquely identify a crystalline phase of a pure material by incorporating into its label the following information: (i) phase identifier, (ii) temperature of formation, (iii) pressure of formation, (iv) whether it forms as the temperature (or pressure) is being raised or lowered, and (v) the phase identifier of the immediately preceding phase.

Examples of the application of this phase-labeling nomenclature will be presented, along with a comparison of this system with that proposed by the IUCr Working Group on Phase Transition Nomenclature [Acta Cryst. (1998) A**54**, 1028]. Hysteresis effects, solid solutions, and label compactness are some of the topics the Working Group did not fully address.

P11.19.012 PHASE TRANSFORMATIONS IN TITANIUM OXYCARBIDE. M.Yu.Tashmetov, V.T.Em [1], B.N.Savenko, G.Batdemberel [2], [1] Institute Nuclear of Physics Uzbekistan Academy of Sciences, Uzbekistan, [2] Joint Institute Nuclear of Research, Russia.

According to theory, the ordering in interstitial phases is principially caused by the deformation interaction between the interstitial solutes. It is known that in interstitial phases interaction between the interstitial solutes determines crystall structure and its properties. In this work X-ray and neutron diffraction methods used to investigate phase transformations in titanium oxycarbide.

The titanium oxycarbide were found to have cubic (sp.gr.Fd3m) and trigonal (sp.gr.P3121) ordered structures. In the space group Fd3m,the Ti atoms occupy the 32(e) positions whereas the carbon and oxygen atoms occupy the 16(c) and 16(d) octahedral interstitial positions. In the trigonal structure, the titanium atoms occupy position 6(c), while the carbon and oxygen atoms occupy positions 3(a) and 3(b). In both ordered structures the metal atoms are shifted from vacancies toward the nonmetal atoms, also positions 16(c) and 3(b) are partially occupied by nonmetal atoms. The cubic ordered structure (sp.gr.Fd3m) is low temperature phase and high temperature phase is trigonal. At 1020K trigonal ordered phase decomposes into two phases. Phase transformations takes place according to the following scheme:
Cubic (Fd3m)→Trigon(P3121)→Ti+Trigon(P3121) →Ti+Cubic(Fm3m)

P11.19.013 X-RAY DIFFRACTION AND CALOR-IMETRIC STUDIES ON PHASE TRANSITION IN $CsPbCl_3$. Y.Yoshimura, Y.Kawase, C.Kimura, H.Iwasaki [1], A.Kojima [2], K.Tozaki [3], [1] Faculty of Science and Engineering, Ritsumeikan University, Kusatsu, Shiga 525-8577, Japan, [2] Department of Materials Science, The University of Shiga Prefecture, Hikone, Shiga 522-8533, Japan, [3] Department of Physics,Faculty of Education, Chiba University, Inage, Chiba 263-8522, Japan

A "hyperfine multistage transition" within 0.1 K was first observed at the 320 K transition in $CsPbCl_3$. Besides this transition, the crystal undergoes phase transitions at 315 and 310 K, explained by the condensation of a soft phonon mode. Another phase change was also reported to exist at 200 K. Hence, X-ray photographic and calorimetric studies were performed over the wide temperature range 340 - 90 K, to make clear the whole transition mechanism. On cooling from room temperature, at approximate 260 K, an abrupt increase of intensity was observed at R- and X-point superlattice reflections appeared at 315 and 310 K transition, respectively. No increase was, however, observed at the temperature concerning M-point appeared at 320 K transition. Corresponding to the X-ray data, a little change of the baseline was observed by means of heat flow measurements. These results suggest there is a new structural phase transition at 260 K and also heterogeneous structural change takes place from the 320 K.

P11.19.014 THE CRYSTAL STRUCTURE OF SPINEL-TYPE $CuIr_2S_4$ AT LOW TEMPERATURE. H. Ishibashi, T. Sakai and K. Nakahigashi, College of Integrated Arts and Sciences, Osaka Prefecture University, Gakuen-cho 1-1, Sakai, Osaka 599-8531, Japan, and R. Oshima, Research Institute for Advanced Science and Technology, Osaka Prefecture University, Gakuen-cho 1-2, Sakai, Osaka 599-8570, Japan.

We have studied the crystal structure of a spinel-type compound $CuIr_2S_4$ at low temperature by using powder X-ray and electron diffraction. $CuIr_2S_4$ is known to show a metal-insulator transition at T_t = 230 K with a structural transition from cubic phase to tetragonally distorted one[1]. However some weak reflections cannot be explained by the assumed structure, therefore, the crystal structure below T_t has not been determined completely.

The high resolution powder X-ray diffraction experiments at 50 K were performed by using synchrotron radiation at Photon Factory in Tsukuba. The powder pattern shows that 400 and 440 reflections split into three and six peaks, respectively, where the basis vectors are corresponding to the cubic axis in the high temperature phase, therefore the crystal structure of the low temperature phase has a triclinic symmetry. Furthermore, there appear many superlattice reflections which are indexed by h, k, l = (all half integer) such as 1/2 1/2 1/2 and (all integer). Consequently, all reflections including superlattice ones can be indexed by assuming a triclinic structure with the cell parameters of a = 19.3787 Å, b = 11.9480 Å, c = 6.9841 Å, α = 91.02°, β = 90.04°, γ= 144.27°. The new unit cell vectors $\boldsymbol{a}$, $\boldsymbol{b}$ and $\boldsymbol{c}$ are given by $\boldsymbol{a} = 2\boldsymbol{a}'$, $\boldsymbol{b} = (-2\boldsymbol{a}' + \boldsymbol{b}' + \boldsymbol{c}')/2$ and $\boldsymbol{c} = (-\boldsymbol{b}' + \boldsymbol{c}')/2$, where $\boldsymbol{a}'$, $\boldsymbol{b}'$ and $\boldsymbol{c}'$ are lattice vectors corresponding to the cubic axis. This structural model also can explain the results of electron diffraction pattern. The detail of the atomic displacements of each atom will be discussed in the conference.

P11.19.015 ^{7}LI AND ^{23}NA SPIN-LATTICE-RELAXATION IN $LINASO_4$. H.-C. Freiheit, A. Fischer, H. Kroll, A. Putnis, Institut für Mineralogie, Muenster, Germany

$LiNaSO_4$ is a plastic crystalline at high temperatures, where Na atoms become highly mobile. The phase transition relating from the trigonal LT-phase (*P31c*) to the superionic conducting phase (*Im3m*) occurs at T_{tr}=788K. It has a pronounced first order character. Anomalies in the heat capacity C_p, the cell volume V and the isotropic displacement parameters of the oxygen atoms $B(O)$ observed at T>500-600K indicate a continuous increase of the orientational disorder of the SO_4-groups well below T_{tr} [1]. The phase transition may thus be triggered by the rotation of SO_4-groups in the low temperature form. In addition coupling between the rotation of the SO_4-groups and the cationic motion is to be expected. In order to verify the supposed transition model we have carried out T_1-spin-lattice-relaxation measurements for ^{7}Li at 155.5 MHz and16 MHz using a (n·90°-τ-90°)-acquisition – and ^{23}Na at 105.8MHz and 16 MHz using a (180°-τ-90°)-acquisition. A mono-exponential recovery of the magnetization at all temperatures is observed for the Li nucleus at both Larmor frequencies and for the Na nucleus at 16MHz. At 105.8MHz the Na nucleus shows a bi-exponential behaviour below 550K resulting in two relaxation times T_{1a} and T_{1b} due to quadrupole interactions [2]. At low temperatures the relaxation is slow for both nuclei with a slight temperature dependence ($\propto T^2$) due to phonons. Above 550K the relaxation rates follow a BPP-behaviour ($T_1 \propto \omega^2$). The change from phonon-induced relaxation to BPP-behaviour at 550K, i. e., the onset of "successful" jumps, indicates a coupling of the cationic motion and the SO_4-rotation according to the trigger-model.

P11.19.016 ELASTIC SCATTERING FROM INTERMEDIATE STATE IN AUCD ALLOYS. T. Ohba [1], K. Sato [1] and K. Otsuka [2]. [1] Dept. of Materials Science and Engineering, Teikyo University, 1-1, Toyosatodai, Utsunomiya, 320-8551, Japan. [2] Institute of Materials Science, University of Tsukuba, Tsukuba, 305-8573, Japan.

Martensitic transformation is understood to be a diffusionless and displacive transformation. It has been utilized a steel hardening and it is an origin of shape memory effect of alloys. Despite of many industrial applications of martensitic transformation, fundamental research of martensitic transformation has not completed yet. 'Phenomenological theory of martensitic transformation' was proposed in 1950's and successive researches revealed that macroscopic feature such as habit plane, twin plane of martensite were described well by the theory. However, mechanism of transformation from microscopic point of view was not solved completely. AuCd alloy is one of typical alloys which shows martensitic transformation. It has distinct martensite called gamma2' and zeta2' close to equi-atomic composition. gamma2' phase appears close to Au-47.5at%Cd and zeta2' phase appears close to Au-50at%Cd. Crystal structure of gamma2' martensite is produced by alternative motion of (110) plane and that of zeta2' is produced by motion of every three planes of (110). Phonon softening, which correspond to the above and is attractive picture of transformation, were observed for both composition alloys. X-ray measurements were performed around 1/3 and 1/2 reflections at parent phase. Considering crystal structure of gamma2' martensite, 1/2 reflections were expected in composition of Au-47.5at%Cd. However no extra reflection was observed at 1/2 position in Au-47.5at%Cd. Diffuse scattering were observed at 1/3 position for both composition and different feature was observed for each composition. When temperature was lowered below transformation temperature, the diffuse scattering was split into two reflections corresponding to martensite phase. This means that diffuse scattering observed at parent phase did not come form martensite and that intermediate state exists prior to the transformation.

P11.19.017 THE ELASTIC SOFTENING UNDER THE COMMENSURATE - INCOMMENSURATE PHASE TRANSITION. V.K.Yatsenko[1], I.N.Mochtchenko[2], A.N.Sadkov[1], V.I.Snejkov[2], [1]Institute of Physics, Stachki 194, Rostov-on-Don, 344090, Russia, [2]North Caucasus Scientific Center, Pushkinskaia 140, Rostov-on-Don, 344006, Russia.

The monocrystal of $Na_{4.5}FeP_2O_8$ (NFP) superionic (presented by H.B.Bolotina, B.A.Maximov, Crystallography Institute of RAS) was investigated by acoustic methods in the 20° - 550° C region. The elastic anomaly under the commensurate – incommensurate phase transition (about 440° C) was observed. The elastic modulus C_{33} is decrease under the increasing of temperature. However the inverse dependence is observed for range 440° - 550° C with sharp minimum at 440° C and slow maximum at about 550° C. In this temperature region the intensities of the main reflections are decrease and of the satellite ones are increase [1]. Two variants of the structure may cause such behavior. The first is the mixture of the phases. The second is the intermediate state with the superlattice formed by the commensurate phase modulated by the incommensurate one. In the framework of the phenomenological theory of the phase transition the temperature dependencies of the elastic moduluses were calculated for both cases. The theoretical results correspond

to the experimental ones for the second variant and it show that softening of phason mode inducing the modulation in the intermediate phase causes the elastic anomaly. Hence in the NFP superionic under the heating occur two phase transitions: commensurate – intermediate states and intermediate - incommensurate states. The measuring and theoretical calculation of the temperature dependencies of the conductivity confirmed this and showed that the superionic properties arise only in the last phase and that the superlattice of the intermediate state was modulated along one direction.

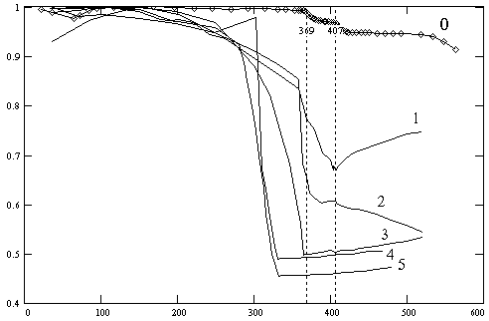
P11.19.018 COMPLEX INVESTIGATION OF THE SUPERIONIC COMPOUNDS. A.N.Sadkov[1], I.N. Mochtchenko[2], V.K.Yatsenko[1], [1]Institute of Physics, Stachki 194, Rostov-on-Don, 344090, Russia, [2]North Caucasus Scientific Center, Pushkinskaia 140, Rostov-on-Don, 344006, Russia.

In 20° C - 550° C temperature region the x-ray, acoustic and electrophysics measurements were performed for superionic compound consisting from the CuI matrix and Al_2O_3 addendum (0-25 mol.%). The x-ray structure investigations showed that the γ-β phase transition temperature is decreased when the Al_2O_3 concentration is increased. The acoustic measurements confirmed this result. For example, the temperature dependence of the longitudinal sound velocity for different Al_2O_3 concentrations (0-0%, 1-5%, 2-10%, 3-15%, 4-20%, 5-25%) is presented in figure.



The γ-β phase transition is clear indicated by the sharp full of the velocity. It was also obtained that at the temperature above 200° C the Al_2O_3 addendum in CuI lead to the softening of the elastic moduluses. These results show that the intermediate interphase boundary layer occupies macroscopic region and forms all physical properties of superionic compound.

P11.19.019 NONEQUILIBRIUM STATES IN SOLIDS AS STUDIED USING THE MOST POWERFUL NEUTRON SOURCE IBR-2. G.M.Mironova, Frank Laboratory of Neutron Physics, JINR, 141980 Dubna, Moscow reg., Russia

The unique experimental tool – angle-resolved TOF neutron transmission and scattering method developed at the most powerful neutron source IBR-2 has been applied to investigations of nonequilibrium state of matter in real time. Thermal shock (sample heating-cooling) acts as a kind of a pump and induces a response in the sample consisting in after-bleaching or after-absorbing in the small angle scattering region. The strength of the effect depends on the material, point of temperature reverse and prehistory of the sample. The details of the responses are very similar to those occurring at the phase transition temperatures. General mechanism of these phenomena is proposed.

P11.19.020 METHOD OF DETERMINATION OF MULTI-k STRUCTURES. A.V.Yeremenko, Department of Magnetism, Institute for Low Temperature Physics and Engineering, Kharkov, 310164 Ukraine, and Yu.G.Pashkevich, Donetsk Phystech Institute, Donetsk, 340114 Ukraine.

A new method of determination of the multiple spin-density wave states (multi-**k** structures) in crystals is proposed. By historical tradition the most part of neutronograms has been interpreted *a priori* as the domains of collinear magnetism. However, the latter one (1**k**-structure) has no advantages and, therefore, is a particular case of the multi-**k** structures. Besides, despite of the essential progress of the magnetic neutronography methods, the problem of determination of the multi-**k** structures is still very difficult to solve either for homogeneous magnets, or for inhomogeneous structures.

An alternative method of determination of the multi-**k** structures is based on the symmetry analysis of the spin-dependent first order (one-phonon) infrared absorption in crystal exhibiting crystallographic cell replication at the Neel temperature. This phenomenon has been theoretically predicted and experimentally found in the exchange-noncollinear, but coplanar magnet Nd_2CuO_4 [1]. In the present report we discuss different effective mechanisms of infrared absorption in non-coplanar structures like UO_2 with the special emphasis on the related problem of crystal structure distortions, and also in magnetic spiral structures. The proposed method has to stimulated experimental and theoretical reinvestigation of the a wide set of magnetic crystals.

This research is supported in part by INTAS (grant 96-0410).

P11.19.021 ON THE GROUND STATE OF NaV_2O_5. Tapan Chatterji, Institut Laue-Langevin, B.P. 156X, 38042 Grenoble Cedex, France, and Max-Planck-Institut für Physik Komplexer Systeme, Dresden, Germany, G.J. McIntyre, Institut Laue-Langevin, B.P. 156X, 38042 Grenoble Cedex, France, and A. Revcolevschi, Laboratoire de Chemie des Solides, Université Paris XI, F-91405 Orsay, France

The recent discovery of a spin-Peierls-like ground state in the inorganic system α′-NaV_2O_5 has induced many investigations. Magnetic susceptibility measurements on both polycrystalline samples and single crystals have shown that a spin gap opens below $T_{SP} \approx 34$ K, and X-ray diffraction measurements showed superstructure reflections corresponding to the propagation vector [(*k*)\vec] = $^1/_2,^1/_2,0$) below T_{SP}. We have performed X-ray and neutron diffraction measurements on single crystals of α′-NaV_2O_5. Least-squares refinements of the structure models against the X-ray and neutron diffraction data at room temperature were performed in both the centrosymmetric (*Pmmn*) and the non-centrosymmetric ($P2_1mn$) space groups. A comparison of these two refinements led us to conclude that the space group of α′-NaV_2O_5 is the centrosymmetric *Pmmn* and not the non-centrosymmetric $P2_1mn$ as claimed previously. There is therefore only one symmetry independent V atom in the unit cell and to describe the structure as having magnetic V^{4+} chains separated by non-magnetic V^{5+}-chains along the b axis is not correct, at least not at room temperature. Instead one should consider zig-zag chains of crystallographically indistinguishable V ions with an average valence of 4.5. We detected superlattice reflections below $T_{SP} \approx 34$ K corresponding to the cell doubling along a and b and quadrupling along c both by X-ray and neutron diffraction. We measured the intensities of several main and superlattice reflections at 5 K by using a neutron wavelength of 1.26 Å. The superlattice reflections are very weak being of the order of about 10^{-4} of the main reflections. We have also measured the intensities of the main and the superstructure reflections by synchrotron X-

ray diffraction at T = 15 K. Joint refinement of the X-ray and neutron diffraction data has led us to a possible model of the low-temperature structure of α'-NaV_2O_5.

P11.19.022 AVERAGED STRUCTURE RESPONSE TO SUPERCONDUCTIVITY. V.N.Molchanov and V.I.Simonov Institute of Crystallography RAS, Leninsky prospect 59, 117333, Moscow, Russia

The behaviour of the crystal structure during the phase transition to the superconducting state is one of the most important problems concerning superconductivity phenomena. Detailed comparison of our precision X-ray diffraction studies of $Tl_2Ba_2CaCu_2O_8$ and $YBa_2Cu_4O_8$ single crystals with some published results on other high-T_c superconducting samples provides the following insights into averaged structure response to charge (hole) redistribution upon the phase transition to the superconducting state.

The most significant changes in the interatomic distances involve oxygen atoms in the CuO_5 pyramid with short in-plane Cu-O bonds and a longer bond to apical oxygen. The Cu-O(apical) distance is minimal exactly in the vicinity of T_c, thus reflecting charge redistribution between the 'reservoir layer' and the 'superconducting slab' *via* the bridging oxygen atom. It should be noted that longer Cu-O apical bonds, such as in Tl-based superconductors, decrease more readily than shorter bonds in yttrium compounds. This effect is accompanied by a small jump-like decrease of Cu-O and/or O-O distances in CuO_2 plane. Both effects clearly indicate an increasing of formal positive charge of Cu atom, thus reflecting transfer of a small portion of holes from reservoir layer to CuO_2 planes. It seems to be the common structural feature for hole-doped high-T_c superconductors.

Anomalous changes of atomic displacement parameters of in-plane oxygen atoms could be interpreted in terms of the strengthening of Cu-O bonds, decreasing or increasing of rotational instability of CuO_5 pyramids and hardening of thermal vibration along *c*-axis. Also, these effects must be closely related to the changes in the character of locally correlated dynamic displacements of atoms above and below T_c.

This work was financially supported by the Russian Scientific Council on High Temperature Superconductivity, Project No 96077.

P11.19.023 MARTENSITIC TRASFORMATION AND MAGNETIC TRANSITION OF HEUSLER-TYPE Ni_2MnGa-BASED COMPOUNDS. Kazuko Inoue, Kazuyuki Enami [1], Yasuo Yamaguchi, Kenji Ohoyama [2], [1] Fac. Sci. & Tech., Ryukoku Univ., Otsu, 520-2194, Japan, [2] IMR, Tohoku Univ., Sendai, 980-8577, Japan

We replaced some atoms of Heusler-type Ni_2MnGa compounds with the other kind of atoms, in order to bring the martensitic transformation temperature (about 200K) and the Curie temperature of mother Heusler alloy (about 370K) close to the room temperature. Then we can control the martensitic transformation using the external magnetic field at room temperature and the shape memory effect originated from the transformation. In the case of $Ni_2(Pd_{0.16}Mn_{0.84})Ga$, we have been able to bring the two transformation temperatures near to the room temperature. We have made the magnetization measurements and the powder neutron diffraction of this material and investigated the phenomena occurring around the transformation region. From magnetization measurements, the martensitic transformation temperature is near 280K and the Curie temperature is near 310K. Rietveld analysis of the powder neutron diffraction pattern of cubic paramagnetic phase at 400K shows that the best fitting is obtained when Pd atoms exist on Ga sites and the eliminated Ga atoms go to Mn sites. At low temperatures, two structures coexist, those are, an orthorhombic structure distorted from the cubic structure and a monoclinic structure with the periodic shuffling of 6 layers of (220) planes of this orthorhombic one. Between 280K and 350K, three structures coexist and the mass fraction of the cubic structure increases gradually with increasing temperature.

P11.19.024 DIRECT OBSERVATION OF CHARGE-ORDERED STATE IN NaV_2O_5. H. Nakao, K. Ohwada, N. Takesue, Y. Fujii, M. Isobe, Y. Ueda , ISSP, University of Tokyo, 7-22-1 Roppongi, Tokyo 106-8666,Japan, M. v. Zimmermann, J. Hill, D. Gibbs, J. Woicik, BNL, Upton, NY 11973-5000, USA, I. Koyama, and Y. Murakami, Photon Factory, KEK, Tsukuba, Ibaraki 305-0801, Japan.

A mixed valent compound NaV_2O_5 [1] undergoes an exotic phase transition associated with its spin, charge and lattice systems at T_C = 35 K. Recent X-ray[2], NMR[3], and theoretical[4,5] works imply that all V-sites are equivalent as a mixed valent state of V^{4+} and V^{5+}, namely an average valence of $V^{4.5+}$ (*disorder model*), above T_C. The crystal structure and charge ordering pattern below T_C, however, are still open question. The charge-ordered state is theoretically predicted as either *chain model* [4] or *zigzag model* [5]. In order to experimentally analyze the charge ordered state of V atoms above and below T_C, we have carried out X-ray anomalous scattering experiments at PF (KEK) and NSLS (BNL). By this method using the *K*-absorption edge, we can obtain an exclusive information on V atoms. The absorption energies of V^{4+} and V^{5+}, moreover, are different by about 1.8 eV; therefore, one can distinguish between V^{4+} and V^{5+}.

We have succeeded in observation of the anomalous energy dependence of superlattice peaks such as ([15/ 2],$^1/_2$,$^1/_4$) and ([17/ 2],$^1/_2$,$^1/_4$) indicating charge ordering. These anomaly can be successfully explained only by the *zigzag model*, while the *chain model* is ruled out. Moreover, the order parameter of the charge-ordered state, i.e. the charge disproportionation, was found to continuously develop below T_C.

P11.19.025 STUDY OF THE METASTABLE EXCITED STATE MS1 OF $Na_2[Ru(NO_2)_4NOOH]2H_2O$ BY SYNCHROTRON RADIATION. A. Puig-Molina, H. Müller, H. Graafsma, Å. Kvick, European Synchrotron Radiation Facility, 38043 Grenoble, France.

$Na_2[Ru(NO_2)_4NOOH]2H_2O$ is a photochromic material suitable for information storage on the basis of long-living metastable excited states [1]. The study of its metastable excited state MS1 by synchrotron X-ray diffraction and IR spectroscopy is presented. A phase transition was detected at 240K by differential scanning calorimetry. The structure at 298K exhibits the C2/m monoclinic space group. The low temperature structure exhibits the P21/n monoclinic space group. The study of the low temperature phase by synchrotron X-rays diffraction is also presented.

The IR spectroscopy was carried out at 80K on laser light-excited sample. It showed the appearance of a new band at 1792 cm^{-1} corresponding to the ν(NO) stretching mode. The band disappeared above 210K.

Synchrotron X-rays diffraction data was collected on laser-irradiated $Na_2[Ru(NO_2)_4NOOH]2H_2O$ monocrystals at ID11 at the ESRF using the Brucker Smart CCD at 110K and 50.2KeV. In the analysis of the excited data different models were used for the geometry of the MS1 taking in account the IR results and considering excitation percentages from 0 upto 50%. The best

results were obtained with a rigid body model for the ground state and MS1 molecules with freedom to refine the Ru-N-O geometry of the MS1 molecules considering 20-30% of the molecules in the excited state MS1. An agreement factor R of 7.86% for 1732 and 52 parameters (isotropic refinement) was obtained with this model. The excited state shows an increase in the N-O distance by 0.19(5) Å as well as a decrease in the Ru-N-O bond angle by 6(2)º relative to the ground state geometry.

20. SYMMETRY AND ITS GENERALISATIONS

P13.20.002 ALGORITHMS FOR DERIVING CRYST-ALLOGRAPHIC SPACE-GROUP INFORMATION. R.W. Grosse-Kunstleve Yale University, New Haven, Connecticut 06520-8114, U.S.A.

Algorithms are presented for 3-dimensional crystallographic space groups, handling tasks such as the generation of symmetry operations, the characterization of symmetry operations (determination of rotation-part type, axis direction, sense of rotation, screw or glide part and location part), the determination of space-group type (identified by the space group number in the International Tables for Crystallography) and the generation of structure-seminvariant vectors and moduli. The latter are an algebraic description of allowed origin shifts, which are important in crystal structure determination methods or for comparing crystal structures.

The space-group type determination produces a change-of-basis matrix which transforms a given space-group representation to the standard one according to the International Tables. This change-of-basis matrix can be used to transform symmetry related information which is difficult to generate from first principles, but easily tabulated for the standard space-group representations, for example asymmetric units and Euclidean normalizers.

The algorithms were implemented and tested using the SgInfo library, which is written in the programming language ANSI C. The source code can be obtained free of charge for non-commercial applications.

P13.20.003 ANTISYMMETRY OF PLASTIC DEFORMATION M.Sh.Akchurin, R.V.Galiulin [1] [1] Shubnicov Institute of Crystallography, Russian Academy of Sciences, Moscow, Russia

We suggest the experimental results of the motion of point defects in fields of mechanical stress in a (Y, Al)-garnet crystal in which the center of inversion is replace by an anticenter. It connect the directions of motion of interstitial atoms with the directions of motion of vacancies. In such way, a crystal acquires the ability to remove the stress arising under the action of various mechanical factors. This experiment show, the motion of interstitial atoms and vacancies is not necessarily associated with dislocation. The absence of the center of inversion in these crystals was checked by morphological methods. The discrepancy between the symmetries determined by the X-ray and the morphological methods was noticed earlier. We believe that the well-known controversy between A.V.Shubnikov and N.V.Belov about which method is more appropriate for determining the crystal structure - morphology or the X-ray structure analysis - can be solved based on the consideration of antisymmetry. In the light of the above consideration, we can state that the reduction of the symmetry group indicated by the morphological methods is associated with the change of the center of symmetry to the anticenter, which can hardly be recorded by the X-ray diffraction method.

P13.20.004 A MODEL WITH P1 SYMMETRY, SHOWING CUBIC SYMMETRY M3M IN DIFFRACTION. Takeo Matsumoto and Sinichi Hashimoto, Dept.Earth Sciences, Faculty of Science, Kanazawa University, Kakumamachi, Kanazawa, 920-1192, Japan.

Enhancement of diffraction symmetry, which means the appearance of a higher Laue symmetry than normally expected, has been reported by several authors. This is caused by special relations among the symmetry operations in the unit cell, and has been theoretically studied mainly in Japan.

Sadanaga and Ohsumi (1979) have shown that the symmetry of diffraction equals to the point group symmetry of the corresponding vector set and arrived the conclusion that an enhanced vector symmetry necessarily leads to a structure built up according to self-homometry or a certain space groupoid. Many examples and models with enhancement of diffraction symmetry have been reported, however, the structure model of triclinic symmetry, showing the cubic symmetry in diffraction, has not been reported.

Here we show such a model. The structure is composed of the same 7x7x7 atoms. The lattice is metrically cubic, and three homometric mates on three axes (Patterson,1944). The atomic parameters as follows;

A:1/16{0,1,2,3,6,11,15},B:1/16{0,1,2,3,5,6,10},
C:1/16{0,1,2,3,6,7,14}.

One plane configuration denoted A*B has been derived by modified convolution of A with B, where B is homometric with A. In this case, the A*B configuration corresponds to the intersections of xj in A and yk in B, where 1ÅÖj,kÅÖ7. Although this plane model is triclinic (plane group:p1, point group:1), its vector symmetry (diffraction symmetry) is not triclinic but tetragonal,4mm. The B*C and C*A configurations are the same situation.

Moreover, a model denoted A*B*C, is obtained in the same way by convolution of A*B with C. The space group of this model is P1, point group 1, however, the diffraction symmetry (vector symmetry) is m3m. Then this structure should show the enhancement of diffraction symmetry, if anomalous dispersion can be ignored. There are special phase relations, in addition to Friedel's law, among 48 reflections (corresponding to equivalent reflections in m3m), such as αhkl+αlhk+αklh = αlkh+αkhl+αhlk.

This model shows the highest enhancement of diffraction symmetry (from 1 to m3m).

P13.20.005 SYMMETRY OF SURFACE. Yu.M. Smirnov, Tver State University, Zheliabova Str., 33, 170000 Tver, Russia

According to Gyarmati [1] the tensor of pressure for moving liquids and gases has the form $\vec{\vec{P}} = (p + p^v)\vec{\vec{\delta}} + \vec{\vec{P}}^{vs} + \overset{\circ}{P}{}^{va}$, where p is the equilibrium pressure, p^v is the viscous pressure, $\vec{\vec{\delta}}$ is the unit tensor, and $\vec{\vec{P}}^{vs}$ and $\overset{\circ}{P}{}^{va}$ are the symmetrical and antisymmetrical parts of the viscous pressure tensor, respectively.

For p (p^v), $\vec{\vec{P}}^{vs}$ and $\overset{\circ}{P}{}^{va}$ the most general Curie groups will be $\infty/\infty m$, ∞/mmm and ∞/m, respectively. Drawing an analogy, one may express in a similar form the surface characteristics of systems – free energy, tension and stress. The surface free energy (scalar quantity) will be described by the Curie group $\infty/\infty m$, while the Curie group ∞/mmm will be associated with the surface tension (polar tensor of the second rank). Then it follows that the surface tension is an axial vector described by the Curie group ∞/m. The axial vector is dualistic to an antisymmetrical tensor of the second rank [2]. All components of pressures and stresses have a common element in their symmetry groups – inversion, and, from this point of view, they are even tensor quantities [2].

In expressions for energy and work the thermodynamical forces (stresses) are directly connected to the surface change of a system. As an example one may consider a simple equation $dW = \sigma dA$, where A is the surface (area). It follows that the surface should be considered as an even tensor quantity, whose symmetry is described by one of the subordinated Curie groups $\infty/\infty m$, ∞/mmm and ∞/m.

P13.20.006 LINEAR CONTINUOUS INHOMOGENEOUS STRAINS IN QUASICRYSTALS. Serguei Rochal, Igor Lebedyuk Physical Faculty, Rostov State University, 5 Zorge St., Rostov-on-Don, 344090 Russia

Together with the well-known linear phasons, a quasicrystalline symmetry permits the existence of the linear continuous inhomogeneous strains (LCISs) related to the "freezing" of certain vibrational degrees of freedom of the QC lattice [1]. At such strains, the magnitudes of position displacements are proportional to the strain value and the flip-flaps of positions are absent. Under a certain LCIS value, the QC lattice transforms into the appropriate defect average periodic lattice. Manifestations of the LCIS in a reciprocal space lead to a redistribution of intensities of the reflections without changing their positions. In a quasicrystalline structure, LCISs may arise spontaneously with variation of the environmental conditions, e.g., with the decrease of temperature, and forcedly - in the case of application of external fields, e.g., under the action of the linear homogeneous field of stresses. As the phason strains, LCISs contribute to the free energy of the quasicrystal (QC) state of a substance. The spontaneous LCIS may be used as an intrinsic order parameter for describing phase transitions from the QC to the low-symmetry aperiodic structure, whose reflections are indexed by the reciprocal-space basis vectors of the ideal QC. LCISs can be also the non-intrinsic order parameters at different phase transitions from the QC phase, for instance, at the QC-to-crystal transformation [2].

21. APERIODIC AND INCOMMENSURATE STRUCTURES

P13.21.001 STRUCTURE ANALYSIS OF $Bi_2Sr_2PrCu_2O_{8+\delta}$ AND $(Bi_{1-X}Pb_x)_2$ $Sr_2CaCu_2O_{8+\delta}$ SINGLE CRYSTALS USING WEISSENBERG METHOD. Tsong-Jen Lee, Chien-Fon Wan, Chin-Chiang Teo, Ting-I Hsu, Yuping Sun, Huan-Chiu Ku, Yu Huang and Kow-Wei Yeh, Dept. of Physics and Material Science Center, National Tsing Hua University, Hsinchu 300,Taiwan –China.

The difference in the modulated structure for high quality $Bi_2Sr_2PrCu_2O_{8+\delta}$ and $(Bi_{1-x}Pbx)_2Sr_2CaCu_2O_{8+\delta}$ single crystal samples was investigated, using Weissenberg images taken with high intensity synchrotron hard X-ray (λ = 1 Å) in Photon Factory. The two kinds of crystals were prepared by the traveling solvent floating zone and self-flux melting methods, respectively. The crystal symmetry of $Bi_2Sr_2PrCu_2O_{8+\delta}$ belongs to orthorhombic Amaa with lattice parameters: a = 5.490(1), b = 5.525(1), c = 30.425(3) Å. The crystal have a structural modulation along the b-axis with q* = 0.247b* + c*. The effect of Pr substitution for Ca and Pb doping in Bi site on structural modulation of Bi-2212 system is discussed.

P13.21.002 TREATING INCOMMENSURATES AS QUASI-COMMENSURATE. L.Häming, M.Ruf, C.Campana, Application Laboratory, Bruker Analytical X-ray Systems, Karlsruhe, Germany

Incommensurate structures often lead to problems when standard diffractometers equipped with szitillation detectors are used. Either the satellite reflections are not found, or the super-cell will increase the data acquisition time enormously. The first will lead to a data set with reasonable intensity statistics and systematic absences, but finally the structure can not be solved or refined properly. Due to the much bigger number of reciprocal lattice points the later case will keep the instrument busy for weeks.

Modern CCD area detectors like the Bruker SMART can scan the complete reciprocal space. The full three circle goniometer does not miss a single satellite reflection. The short readout time of about one second allows to scan the crystal very time efficient. Once the reciprocal space has been stored these digital information can be interpreted with different unit cell definitions.

Incommensurate problem structures may be treated as quasi-commensurate. The seven fold incommensurate structure of a carbaborane will be presented. The point detector system did give a 7x10x16 Å unit cell. The structure could not be solved nor refined. Therefor the crystals were left on the shelf for many years. Whereas the SMART detector did immediately find the satellite reflections to index on the 49x10x16 Å super-cell. More than 112.000 reflections were collected in a single day on a standard SMART lab system. All hydrogen positions of the seven carbaborane molecules could be found in the difference fourier map. In addition the final model did show two rotational disordered carbaboranes.

Scanning complete reciprocal space with the SMART CCD detector offers an easy and fast way to work on problem structures like modulated structures. Without additional software tools incommensurate structures can be treated as quasi-commensurate.

P13.21.003 FIFTY EIGHT NEW SILICON CARBIDE POLYTYPES. Chang-lin Guo, X-Ray Crystallography Laboratory, Shanghai Institute of Ceramics, Chinese Academy of Sciences, 1295 Dingxi Road, Shanghai, 200050, P.R.China

Silicon carbide is a most typical substance of polytypism. Up to present more than 160 polytypes of SiC are discovered, in which we have discovered 84 new polytypes. In this paper, 58 new silicon carbide polytypes which have been found by using the analytical method of the relationship between lattice points in reciprocal lattice are described. More than 1000 industrial silicon carbide single crystals have been studied by X-ray modified Laue method. 10% of the crystals contained higher-layers polytypes other than basic-types 6H, 15R, 21R, 4H and 8H. High resolution X-ray special Laue photographs were taken for the crystals containing higher-layer polytypes by using the large-diameter (ϕ 153mm) cylindrical camera with very narrow -incident slit[1]. Since the coaxial coalescence of high-layer polytypes with the basic type in silicon carbide is a very general phenomenon, the point relation method [1] based on the analysis of relationships between lattice points of polytypes and the basic type may be considered as the most effective method on the investigation on SiC polytypism. 58 new SiC polytypes we have found as following: 234H, 136H, 133H, 126H, 117H, 114H, 113H, 102H, 87H, 70H, 67H, 30H, 1116R, 1026R, 891R, 879R, 759R, 714R, 585R, 582R, 570R, 543R, 528R, 525R, 519R, 438R, 432R, 423R, 402R, 399R, 396R, 390R, 375R, 372R, $357R_{(a)}$, $357R_{(b)}$, 327R, 324R, 315R, 312R, 309R, 297R, 291R, $267R_{(b)}$, 258R, 255R, 225R, 219R, 204R, $201R_{(b)}$, 198R, 186R, 177R, 144R, 138R, $75R_{(b)}$, 63R and 54R.

The crystal structures of several new polytypes were determined by a special Laue method [2,3]. The crystal structure of $357R_{(a)}$ is $[(33)_{19}32]_3$, $357R_{(b)}$ is $[(23)_{23}22]_3$, $267R_{(b)}$ is $[(33)_{14}32]_3$, $201R_{(b)}$ is $[(33)_{10}34]_3$ and $75R_{(b)}$ is $[(33)_334]_3$.

P13.21.004 INCOMMENSURATE CRYSTAL STRUCTURE OF LAZURITE. N.B. Bolotina, V.I. Simonov, Institute of Crystallography RAS, 117333 Moscow, Russia

Lazurite, a sodalite-group mineral, ideally $Na_6Ca_2(Al_6Si_6O_{24})$ $(SO_4,S)_2$, is known in cubic, orthorhombic, monoclinic and triclinic modifications [1,2], where three last ones are superstructures with linear parameters a, $a\sqrt{2}$, $na\sqrt{2}$ (n - integer) in reference to the cubic cell with parameter a. Given crystal sample from Baikal region corresponds to the case of incommensurate modulation of basic cubic cell, a = 9.07 Å. Satellites are located on six plane diagonals, so that up to 12 satellites could be located at $\pm 0.218a^*\sqrt{2}$ around each main reflection. Average cubic structure corresponds to sp. gr. $P\bar{4}3n$ [1].

To explain observed diffraction pattern and describe the symmetry of modulated structure, different models of modulation are calculated.

(1) There is 3D modulation with wave vectors $q_1 = (\gamma, 0, 0)$, $q_2 = (0, \gamma, 0)$, $q_3 = (0, 0, \gamma)$, $\gamma \cong 0.218$ in the basis of given cubic cell. All satellites are described as the second order ones of the *hkl110* type, whereas the first order satellites of the *hkl100* type are not observed. This fact should be taken into account with extinction rule $m+n+p = 2N$ for *hklmnp* reflections, so that for symmetry description (3+3)D group P23:P23 with additional translation (0, 0, 0, 1/2, 1/2, 1/2) should be chosen. The group P23 is selected instead of $P\bar{4}3n$ on view of intensities of symmetry - equivalent satellites.

(2) There is 3D modulation with wave vectors $q_1 = (\gamma, \gamma, 0)$, $q_2 = (\gamma, 0, \gamma)$, $q_3 = (0, \gamma, \gamma)$, $\gamma \cong 0.218$ in the basis of the same cubic cell. All satellites are separated into two types: the first order satellites

along q_1, q_2, q_3 directions and the second order satellites along three other plane diagonals.
(3) The sample is twin formed by six parts. For a cell of each part, its $a_o b_o$ plane (cell parameters $a_o = b_o = a\sqrt{2}$, $c_o = a$) is coinsident with a side of twinning cubic cell and rotated on 45°, whereas the symmetry of each part is orthorhombic one, its structure is modulated on *x* and *y* directions.

P13.21.005 THE MODULATED STRUCTURE OF QUININIUM (R)-MANDELATE - AN INCOMMENSURATE DESCRIPTION IN SUPERSPACE. A. Schönleber and G. Chapuis, Institut de Cristallographie, Université de Lausanne, BSP Dorigny,1015 Lausanne, Switzerland

In addition to main reflections the diffraction pattern of quininium(R)-mandelate, $C_{20}H_{25}N_2O_2^+ \cdot C_8H_7O_3^-$, exhibits satellites up to very high order. A commensurate structure model in a 15-fold supercell was presented by [1].

In agreement with [1] single crystal diffraction measurements at room temperature and at T = 120 K show no changes in the cell parameters or in the $\vec{q}$ -vector components. The main reflections can be indexed in a $P2_1$ basic cell with one formula unit per asymmetric unit and a =6.57 Å, b = 18.46 Å, c = 10.26 Å and β =107.23°. With respect to this cell, the $\vec{q}$ -vector is $\vec{q} = 0.33\,\vec{a}^{\,*} + 0.27\,\vec{c}^{\,*}$ (T = 120K).

The structure was solved within a commensurate approximation in a 3X5 supercell in $P2_1$ with 15 formula units per asymmetric unit and a = 19.71 Å, b = 18.46 Å, c = 50.27 Å and β =77.29° (T = 120 K).

The results of the refinements of the incommensurate structure with MSR [2] and JANA'98[3] will be presented. The temperature dependence of the satellite intensities in respect to the main reflections will be investigated.

P13.21.006 NEUTRON DIFFRACTION STUDIES OF INCOMMENSURATE MAGNETIC ORDER IN TRANSITION METAL OXOSALTS. J P Wright, J P Attfield [1], J B Forsyth, W I F David, D Martin y Marero [2], [1] Department of Chemistry, Cambridge University, Lensfield Road, Cambridge CB2 1EW, [2] Rutherford Appleton Laboratory, Chilton, Didcot, Oxon OX11 0QX

The use of cold neutrons for long d-spacing powder diffraction at the spallation source ISIS allows very high resolution data to be obtained for the solution and Rietveld refinement of complex magnetic structures. We have used the IRIS and OSIRIS diffractometers to study incommensurate magnetic order in monoclinic $FeAsO_4$ [1] and the isostructural doped compounds $Fe_{(1-x)}Ga_{(x)}AsO_4$ for x=0-8% and $FeAs_{(1-x)}P_{(x)}O_4$ for x=0-16%. The propagation vector of (0.04994(3), 0, -0.24725(2)) indexes the helimagnetic structure in $FeAsO_4$ where the spins of 4.01(2) Bohr magnetons rotate in a plane containing b* and making an angle of 34.1(7) degrees to [001] in beta-obtuse. All of the doped compounds exhibit an analogous magnetic structure to that of $FeAsO_4$, although the propagation vector varies in the ac plane proportionally to the degree of substitution. We have also studied the $CrP_{(1-x)}V_{(x)}O_4$ system (x=0-8%) using the HRPD diffractometer. The cycloidal spiral magnetic structure is incommensurate with the crystal structure, having a propagation vector of (0.3305(2),0,0) for x = 0 and which increases with x. This indicates that any single ion anisotropic effects are too weak to lock this structure into a commensurate configuration, and that the near-commensurate structure arises through a coincidental balance of exchange interactions.

P13.21.007 ON THE DIFFUSE LAYERS IN DECAGONAL AlCoNi QUASICRYSTALS. F.Frey and E.Weidner, Institut für Kristallographie, LMU, 80333 München, Germany, K.Hradil, Institut für Mineralogie, Universität, 97074 Würzburg, M.deBoissieu, LTPCM/ENSEEG, 38042 St.Martin d'Heres, France, and R.Currat, ILL, 38042 Grenoble, France

Diffraction patterns of many decagonal phases exhibit diffuse layers perpendicular to the "periodic" axis c (1(. The layer line distance corresponds to a period 2c in most cases, a period 4c was observed in Al71.5Co16.5Ni11. The layers consist of a homogeneous diffuse background and superimposed short range order maxima (2(. Their widths and positions depend on the exact stoichiometry as well as on the prior thermal history of the sample. A diffuse background exists also beneath the Bragg layers. The layers vanish at high temperatures (3(. The temperature behavior differs from that of other diffuse phenomena within the quasiperiodic planes. From the characteristics in reciprocal space a column-like order along c is concluded. Lateral short range correlations between the columns are responsible for the sro maxima. Co/Ni superorder along c can be excluded due to the results of a neutron diffraction experiment on Al71.5Co16.5Ni12, binary decagonal phases exhibit diffuse layers as well (4(. A chemical superorder can be ruled out due to absent sharp reflections at positions (0000n/2) (n=1,2,..). A displacive disorder along c is most conclusive. A quantitative analysis is performed which is based on a 1D (domain) model consisting of columns of icosahedral clusters. Due to molecular dynamical calculations (5(icosahedral clusters are formed by Al atoms which have left the decagonal layers. As the diffuse layers remain sharp up to high Q-values - shown by neutron diffraction - a long range order of the 1D superstructure exists along c.

P13.21.008 STRUCTURE OF DECAGONAL QUIASICRYSTALS AND THEIR APPROXIMANTS WITH FIVEFOLD ATOM CLUSTERS. K. Saitoh, T. Yokosawa, M. Tanaka [1], A. P. Tsai [2], [1] Research Insitute for Scientific Measurements, Tohoku University, Sendai 980-8577, JAPAN, [2] National Research Institute for Metals, Tsukuba, 305-0047, JAPAN

High-angle annular dark-field (HAADF) images of a melt-quenched $Al_{70}Ni_{15}Fe_{15}$ decagonal quasicrystal and a monoclinic tau2-$Al_{13}Co_4$ approximant have been taken using a scanning electron microscope. We have found that both alloys are composed of 2-nm diameter atom-clusters with fivefold symmetry. Structural models of both alloys have been constructed on the basis of the HAADF images and a structure of the monoclinic $Al_{13}Fe_4$ approximant. Furthermore, we have been constructed, on the basis of the observation of high-resolution electron microscope images, a model of a structural transformation from

the tau2-monoclinic $Al_{13}Co_4$ approximant to the Al-Co decagonal quasicrystal which has the same structure as $Al_{70}Ni_{15}Fe_{15}$.

P13.21.009 SYMMETRY ANALYSIS OF MAGNETIC ORDERING IN RFe_4Al_8 (R=La, Ce, Y, Lu, AND Tb) COMPOUNDS. W.Sikora, Faculty of Physics and Nuclear Techniques, UMM, al.Mickiewicza 30, 30-059 Krakow, Poland, P.Schobinger-Papamantellos, Laboratorium fur Kristallographie, ETHZ, CH-8092 Zurich, Switzerland, K.H.J.Buschow, Van der Waals-Zeeman Institute, University of Amsterdam, 1018 XE Amsterdam, The Netherlands

Representation analysis [1] [2] of the neutron diffraction data of RFe_4Al_8 (R= La, Ce, Y, Lu, and Tb) tetragonal compounds (I4/mmm), for the wave vectors $\mathbf{q}_1=(00q_z)$, and $\mathbf{q}_2=(q_xq_x0)$ [3] leads to various modulated structures. The R atoms at 2(a) positions remain in one orbit in relation to the G_k group for both **q** vectors. The calculations lead to the following models: sin-wave, simple spirals or cycloid spirals . For $\mathbf{q}_2$ the Fe atoms at (8f) positions split into two distinct sets (orbits), which may order independently as sine wave, simple spiral or cycloid spiral structures. The spirals of the two Fe orbits may have different chiralities and even different planes of rotation. For a given model, within each orbit the relation between magnetic moments is fixed by symmetry. This leads to considerable parameter reduction. The phase shift between various orbits, not fixed by symmetry relations, has to be found by data analysis. For $\mathbf{q}_1$, the Fe atoms at 8(f) positions remain in one orbit and there is a large number of sine wave structures described by one irreducible representation of I4/mmm group, with different directions and fixed couplings. All models with components in (001) plane comprise two groups of atoms, the magnetic moments of these groups are either confined to mutually perpendicular planes or are shifted by the phase $\pi/2$. Representation analysis provides a) the full information concerning the free parameters needed for the refinements, b) the order parameters describing the phase transition and their dimension, and c) enables a systematic classification of the used models in the neutron data analysis.

P13.21.010 COMMENSURATE AND INCOMMENSURATE Li^+-ORDERING IN ε- AND ε′-$Li_xV_2O_5$ AS A FUNCTION OF TEMPERATURE. H. Katzke and M. Czank, Institute of Geosciences, Olshausenstr. 40, 24098 Kiel, Germany.

ε- and ε′-$Li_xV_2O_5$ belong to a group of intercalation compounds which are formed during the topotactic intercalation reaction of lithium ions into the host structure V_2O_5. With means of electron diffraction the possibility of superstructure formations, due to Li^+ ordering processes, was studied as a function of temperature. In the course of these investigations a series of thermally induced structural phase transitions was detected, which can be mostly attributed to order/disorder transitions of the intercalated lithium ions. The structural diversity comprises phases with dynamical disorder, incommensurately modulated structures and commensurate phases with statical disorder. In the temperature range 550 K - 110 K two reversible phase transitions can be detected for ε- ($0.32 \le x \le 0.52$) and ε′-$Li_xV_2O_5$ ($0.52 \le x \le 0.80$). The high-temperature phase crystallizes in both cases in the orthorhombic space group *Pmmn* with probably dynamically disordered Li^+ ions. On decreasing temperature, the Li^+ ions order, resulting in incommensurately modulated structures at room-temperature [1,2], and commensurate structures with probably statical disorder at low-temperatures [3,4]. Structural models on the basis of competing interactions of attractive guest/host- and repulsive guest/guest-interactions are proposed for the different states of Li^+-ordering.

P13.21.011 DISTORTIONS OF SECOND ORDER IN THE INCOMMENSURATE CDW STATE OF $NITA_2SE_7$. S. van Smaalen, J. Lüdecke, M. Schneider, Laboratory of Crystallography, University of Bayreuth, D-95440 Bayreuth, Germany

The incommensurately modulated low temperature structure of $NiTa_2Se_7$ has been studied in detail using synchrotron radiation. The modulated low temperature phase is a charge density wave (CDW) state caused by chains of transition metal atoms along the crystallographic b-axis [1]. To determine the modulated structure, satellite reflections up to second order have been measured at a temperature of 15 K. The structure was refined with two harmonics of the modulation functions. Modulation with the first harmonic was found on the Ni atoms and the surrounding Se atoms, which is in good agreement with an earlier investigation [2]. As a surprising result, the modulation with the second harmonic appeared on completely different atoms. One of the Ta chains was modulated longitudinally. The distortions of first and second harmonic on different parts of the structure clearly rules out the latter to be a second-order effect. This result is in agreement with the temperature dependence of the q and the 2q critical scattering observed by electron diffraction above T_{CDW}. It indicated different origins of both distortions. A complete understanding of the observed distortions has not been achieved yet.

P13.21.012 WEAK BRAGG SCATTERING IN ICOSAHEDRAL Mg-Y-Zn. M.A. Estermann, T. Haibach, A. Cervellino and W. Steurer, Laboratorium für Kristallographie, Eidgenössische Technische Hochschule, ETH-Zentrum, CH-8092 Zürich, Switzerland.

At present, Mg-Y-Zn is the best ordered quasicrystalline material available, and with crystal sizes suitable for neutron diffraction experiments. No disorder diffuse scattering was observed in our sample which had the composition $Mg_{29}Y_9Zn_{62}$. Therefore it is possible to address the nature of perfect quasiperiodic ordering directly, without the need to include short-range structural disorder in the analysis of the perfect long-range order. The obvious question is whether the present Mg-Y-Zn phase is an ideally perfect crystal in accordance with the mathematical framework of higher-dimensional crystallography [1]. Of particular interest are the weak intensities of the Bragg peaks with high perpendicular component of the scattering vector, and the study of possible structural models. To clarify this question experimentally, two diffraction experiments were performed. One experiment was performed at the HASYLAB synchrotron radiation source with a fixed wavelength rotation geometry set-up and a marresearch imaging plate detector system. Software was developed to index the data automatically and to produce arbitrary slices through reciprocal space [2]. The other experiment was performed at the ISIS time-of-flight neutron spallation source with the SXD Laue diffractometer. The results of this two complementary studies will be presented.

P13.21.013 THE QUASICRYSTAL MODELS WITH THE DISCRETE SPECTRUM. E.V.Olchanskaia, I.N.Mochtchenko, A.M.Mojaev, North Caucasus Scientific Center, Pushkinskaia 140, Rostov-on-Don, 344006, Russia.

The quasicrystal models characterised discrete Fourier images are presented. The models were constructed by using the quasilattice algorithm early elaborated. The spectrums of these models were investigated by analytical methods and the methods of quantity analysis including the theory of approximation of the integral functions. The structures with discrete spectrum were selected. The examples of such models are the quasilattices with the knots determined by the maximum of the next functions:

$Z=\max(\cos k_i r)$, $k_i=(\cos(2\pi i/5); \sin(2\pi i/5))$, $i=0\ldots4$; (1)

$Z=\Sigma(\cos(k_i r))$, $k_i=(\cos(2\pi i/5); \sin(2\pi i/5))$, $i=0\ldots4$; (2)

Then spectrums were numerical calculated using regularisation methods. The elaborated models and their spectrums are the base elements for the determination of the quasicrystal structures from diffraction data. For example, using the model (1) we approximated the experimental data and calculated the quasicrystal structure as a Fourier image of the model. The result is presented in figure (left), where the high-resolution electron micrography is also presented (right) for comparison.

22. CRYSTALLOGRAPHIC TOPOLOGY

P13.22.001 ENUMERATION OF CRYSTAL-STRUCTURE TYPES USING A FINITE SUPERGROUP OF ALL THE BRAVAIS LATTICES. Masahiko Hosoya Dept. of Physics, University of the Ryukyus, Senbaru 1, Nishihara, Okinawa 903-0213, Japan

A finite group was found which derives all the Bravais lattices as its subgroup. The analysis of its structure enables us to enumerate many crystallographic objects such as the point groups automatically. Especially this method is useful when it is applied to the enumeration of crystal-structure types. Every crystal-structure type is regarded as a Bravais lattice type in the higher-dimensional space.

P13.22.002 SELF-INTERSECTING MINIMAL SURFACES: SPATIAL SUBUNITS AND LABYRINTH GRAPHS. Elke Koch, Institute for Mineralogy, University of Marburg, D-35032 Marburg, Germany.

Three-periodic minimal surfaces with self-intersections along straight lines subdivide R^3 either into a finite number of three-periodic spatial subunits (labyrinths) or into infinitely many two-periodic, one-periodic or finite spatial subunits (flat labyrinths, tubes or polyhedra, respectively).

So far, 78 different families of such self-intersecting minimal surfaces have been derived with the aid of skew polygons formed by the even-fold rotation axes of some space group [1, 2], and their geometrical and topological properties have been analysed. Their Euler characteristics χ vary between −3 and −20. Most of these surfaces (68 families) are non-orientable.

The minimal surfaces of 47 families subdivide R^3 into a finite number of congruent, three-periodic labyrinths with Euler characteristics χ_{lab} between −4 and −24. Two labyrinths occur 42 times, four labyrinths 3 times and eight labyrinths 2 times [3].

Congruent flat labyrinths are generated by the minimal surfaces of 14 families [4]. In most cases (11 families) all flat labyrinths run parallel. The flat labyrinths of 3 families, however, are subdivided into two sets which run perpendicular to each other.

8 families of minimal surfaces subdivide R^3 into congruent tubes, 1 family into two sets of non-congruent tubes, 3 families into tubes and polyhedra, 1 family into congruent polyhedra, and 4 families into two kinds of polyhedra [5].

P13.22.003 TILINGS ON HYPERBOLIC SURFACES AS REPRESENTATIVES OF CHEMICAL NETWORKS. S. Leoni, R. Nesper, Laboratory of Inorganic Chemistry, ETH Zurich, Universitätstrasse 6, CH-8092 Zurich, CH

The great benefits of using a structure-enveloping continuous function in the description of chemical structures have been exemplified many times [1-3]. The strategy of calculation takes advantage of the topological information contained in the most fundamental structure factors, as was proposed by Nesper and von Schnering [1]. The result is a family of continuous, orientable, 3-periodic surfaces, which resume the symmetry information of a space group. The surface, which corresponds to the roots of the generating function, is called PNS [1]. The consequence of the application of such shapes to periodic structures is the understanding of their organisation. The two-dimensional character of iso-surfaces of such three-dimensional functions reveals a hierarchical organisation of the forces involved in the structures. Further deepening of the relation between symmetry and covalent networks can be gained if a new method is implemented, which allows to design hyperbolic networks directly on the curved shape of a PNS. Two different iso-surfaces are allowed to overlap [3]. The result is a complete covering of the hyperbolic surface by hyperbolic tiles. With this method it is an easy task to redesign the network of well-known zeolites, other networks like the one those of clathrates, but also some hypothetical graphitic-like networks, like those already proposed [4] and finally some completely new networks [3]. This method allows for an easy generation of new networks, but also for an enumeration of all the networks which are compatible with a given curved shape, permitting to grasp the correlation between growing complexity, organisation and hierarchy of the forces.

P13.22.005 AlPdMn QUASICRYSTALS REVISITED. L. Loreto, R. Farinato [1], C. Janot [1,2], [1] Dipartimento di Scienze della Terra, Universita' di Roma 'La Sapienza', P.zzale A. Moro 5, 00185 Roma, Italy, [2] Laboratoire de Cristallographie, CNRS, BP 166 38042 Grenoble Cedex 9, France

The structure of icosahedral quasicrystals of the AlPdMn has been previously investigated using X-ray and neutron diffraction [1]. The result is a periodic image in a six-dimensional space from which it is possible to deduce a physical three-dimensional arrangement of the atoms. This structure is essentially based on atomic clusters whose geometry is close to that of a Mackay icosahedron and that have been termed Pseudo-Mackay icosahedron (PMI). The whole structure can be described as a dense covering of space by overlapping PMI. Two PMI, when overlapping, have in common a double hexagonal-like flat pyramid whose axis is along a two-fold direction. The PMI overlap around vacancy-like sites (t^3 times smaller than a PMI, t=1.618033 the golden number) which are distributed at the vertices of big dodecahedra and icosahedra. Space scans around these vacancy sites show that they are the empty center of pseudo-Bergman clusters (PBC). Indeed, one find two shells of atoms surrounding these vacancies, one icosahedron and one dodecahedron respectively. Further atomic shells are triacontahedra and truncated icosahedra (soccer-ball like). The interesting point is that PBC show up here as a mere consequence of the PMI. If the geometry of the PMI is rather well defined within the whole structure, there is quite a large distribution in their chemical composition and in details of their shapes. Central atoms of the PMI are basically Mn, sometime Pd. The internal shells, or cores, contain an average of 7 atoms that can fluctuate from 5 to 14. The external shell is well defined and is made of 30 sites of an icosidodecahedron plus 12 sites of an icosahedron. The chemical composition of the external shell fluctuates around two main contributions of about 70% and 30% respectively (30Al + 6 to 9Mn + 3 to 6Pd on the one hand; 20 to 23Al + 22 to 19Pd on the other hand). The 66% of the cores are pentagons of Al, with various orientations. Other cores have complex polyhedral shapes with 10 to 14 atoms, mainly Al with occasional Pd. Cluster geometry and composition along with their association rules are basic ingredients that can be used for modelling the structure of real quasicrystals.

P13.22.006 THE GROWTH OF QUASICRYSTALS D. Joseph [1], V. Elser [2], [1] Max-Planck-Insitute for Physics of Complex Systems Noethnitzer Str. 38, 01187 Dresden, Germany, [2] Laboratory of Atomic ans Solid State Physics, Clark Hall, Ithaca NY 14853-2501, USA

The growth of quasicrystals is one of the unsolved problems in condensed matter theory. Although the problem was attacked right at the beginning there is no complete picture at hand. For the class of entropically stabilized quasicrystals we recently proposed a model that circumvents some major concerns. So it is possible to grow macroscopic big samples without violating the limits set by experiment. In this contribution we present the model and discuss its properties in 2 and 3 dimensions.

P13.22.007 ICOSAHEDRAL ORDER AND DISORDER IN Si AND Ge. V.E. Dmitrienko, Institute of Crystallography, 59 Leninski pr., Moscow, 117333, Russia and M. Kléman, Laboratoire de Minéralogie-Cristallographie, Universités Paris VI et Paris VII, 4, place Jussieu, Paris Cedex 05, 75252, France.

Hidden icosahedral symmetry of interatomic bonds is found in four-coordinated phases of silicon and germanium. For example, in the BC8-*Ia* $\bar{3}$ phase, three bonds of each atom are directed almost exactly along *fivefold* icosahedral axes and the fourth bond is directed along a threefold axis. It is shown that this phase may be considered as a 1/0 crystalline approximant of a hypothetical icosahedral quasicrystal with a *body-centred* six-dimensional lattice and that all the atomic positions in BC8 crystals may be obtained as projections from that six-dimensional lattice. The diffraction pattern of the BC8 phase has hierarchical organisation typical of both approximants and quasicrystals.

A specific type of topological disorder, related with phason flips, is suggested. Those phason flips are quite unusual because they lead to 90° rotation of icosahedral directions. The experimentally observed BC8-R8 phase transition can be regarded as resulting from coherent phason flips of this type. The positions of atoms in the perpendicular space and the perpendicular projections of the phason flips are analyzed. It shown that the phason flips may result in many other structures, ordered and disordered, without dangling bonds. The X-ray scattering in the phason-disordered structure is shown to be similar to the scattering in the amorphous Si. A new *scenario* for crystalline-to-amorphous transformation is proposed.

A dual relationship with approximants of conventional quasicrystals is used to construct a 1/1 approximant with *Ia* $\bar{3}$ symmetry (64 atoms per unit cell). In this approximant, the phason flips provide a mechanism of annihilation of dangling bonds. Construction of higher order approximants is discussed.

P13.22.008 TEMPERATURE BEHAVIOUR OF THE DISORDER SCATTERING IN DECAGONAL ALNICO INVESTIGATED BY SYNCHROTRON RADIATION. K. Hradil and R.B. Neder, Universität Würzburg, Institut für Mineralogie, Am Hubland, D-97074 Würzburg, Germany, E. Weidner and F. Frey, LMU München, Institut für Kristallographie und Angew. Mineralogie, Theresienstr. 41, D-80333 München, Germany.

Decagonal phases are two-dimensional quasicrystals (qc) exhibiting translational order along the unique 5- or 10-fold axis and quasiperiodic order perpendicular to it. Diffraction patterns of thermodynamically stable decagonal phases in the Al-Ni-Co systems exhibit, beside very sharp Bragg reflections corresponding to a long-range ordered average structure, disorder diffuse and superorder scattering in the qc layers and along the periodic direction [see e.g. 1]. In this work we focus on the temperature dependence of the disorder and superorder scattering within the qc Bragglayers of a decagonal sample with nominal composition Al:Ni:Co=72.5:11:16.5.

The in-situ temperature measurement was carried out around two Bragg reflections up to 1100 K in reducing atmosphere at the 4-circle-diffractometer at beamline D3, DESY/HASYLAB, Hamburg using a mirror furnace [2]. Both the intensities of the Bragg reflection and the surrounding satellite reflections were collected in **Q**-scan mode with a resolution of 1.5×10^{-4} Å^{-1}.

As evident from two-dimensional **Q**-scans around the $(100\bar{1}0)$ and (10000) Bragg reflections the sample was in a decagonal state at room temperature. A complex temperature behaviour of the disorder diffuse and superorder scattering around these Bragg reflections is observed within the temperature range up to 1100 K. Between 870 K and 990 K a significant intensity decrease of the satellite scattering (30%) can be found. Heating up to 1100 K a remarkable intensity increase is observed. This is accompanied by a broadening of the satellite profiles.

P13.22.009 STRUCTURAL ANALYSIS OF AN $Al_{72}Ni_{20}Co_8$ DECAGONAL QUASICRYSTAL. Hiroyuki Takakura[1,2], Akiji Yamamoto [3], Steffen Weber [3], An Pang Tsai[1], [1] Natonal Research Institute for Metals, Tsukuba 305-0047, Japan.[2]CREST, Japan Science and Technology Corporation, Kawaguchi, Saitama, Japan.[3]National Institute for Research in Inorganic Materials, Tsukuba 305-0044, Japan.

The structure of a water quenched $Al_{72}Ni_{20}Co_8$ ($P10_5/mmc$, c=4.11Å) decagonal quasicrystal has been analyzed using the single crystal X-ray data for the first time by higher dimensional structure analysis. Newly developed softwares for imaging plate Weissenberg camera were used to obtain 607 independent integrated intensities. The $Al_{72}Ni_{20}Co_8$ is belonging to a simple decagonal phase, which shows neither superlattice reflections nor diffuse streaks by electron diffraction [1,2]. Recent structural study based on an electron diffraction has shown that there are small fundamental structure units having a 4Å radius instead of symmetrical 20Å cluster [3]. We confirmed that there is no diffuse scattering even in a sub-millimeter size sample suitable for X-ray scatteirng study. The large occupation domains are located at A:(1,1,1,1,1.25)/5, B:(2,2,2,2,1.25)/5, which are subdivided by more smaller parts. In the analysis, shift from an ideal atom position is introduced. The occupation domain A is similar to that of corresponding one proposed recently in terms of shape and distribution of TM (Transition metals)[4]. This reveals a symmetry breaking of 20 Å decagonal cluster. On the other hand, the distribution of TM in the occupation domain B is somewhat different from that proposed. The $Al_{72}Ni_{20}Co_8$ is only stable as a high temperature phase. It is thus expected that many disorder sites exist in the structure. Indeed, our results suggest that disorder sites exist in real structure.

P13.22.011 NEW GEOMETRIES FOR NEW MATERIALS. Alan L. Mackay, Dept. of Crystallography, Birkbeck College (University of London), Malet Street, London WC1E 7HX, Eric A. Lord, Dept. of Metallurgy, Indian Institute of Science, Bangalore 560012, India and Jacek Klinowski, Dept. of Physical Chemistry, University of Cambridge, Cambridge CB2 1EW.

Modern computational software has facilitated the generation and exploration of a very wide range of intriguing new geometrical structures which may be realisable at any scale between those of mega-engineering and of nanotechnology. Some of these structures are solutions to partial differential equations, corresponding to physical conditions such as minimum area or minimum splay energy, with various imposed symmetries or boundary conditions. Minimisation of energies of aggregates of atoms correspond to levels of organisation above that of individual atoms and molecules. Many of these structures are absolutes, like the Platonic solids, without parameters.

The geometry derives from extensions of classical crystallography following the lead of Delone, Voronoi, Engel and Dress, turning it inside out and working out from the connectivity of the asymmetric unit rather than inwards from the picture-frames of the symmetry elements in the 230 space groups. Elements of surface or of tubes, rather than the isolated atoms of crystal structure, are placed in the various asymmetric domains and connected up. The key advance is in devising notations which can be handled by computer. This approach permits a seamless transition to quasi-periodic and hierarchic structures which arise naturally and which are now beginning to be recognised experimentally as X-ray crystal structure analysis passes to electron microscopy as the dominant method of observation.

The numerous periodic minimal surfaces and the enumeration of periodic networks are recent prominent examples. Stereo-pairs or material models are necessary for the proper apprehension of their topologies.

P13.22.012 CRYSTALLIZATION OF GaMgZn ALLOY NEAR THE QUASICRYSTAL PHASE EXISTENCE REGION. Marian Surowiec and Piotr Jelen, Institute of Physics and Chemistry of Metals, University of Silesia, 40 007 Katowice, Bankowa 12, Poland.

Quasicrystal icosahedral phase is formed in the vicinity of Frank and Kasper intermetallic phases. In the case of GaMgZn alloy corresponding Frank and Kasper phase was determined [1] and it is known as the Bergman cubic phase $Ga_{16}Mg_{32}Zn_{52}$. On the other hand icosahedral quasicrystal phase was found [2] and equilibrium icosahedral single quasicrystal forms with pentagonal dodecaedral growth morphology were observed in shrinkage cavity of GaMgZn ingot [3]. The aim of our investigation was to elaborate process of technology enabling crystallization of the GaMgZn alloy under superpressure and mixed gas atmosphere (nitrogen plus helium) and to perform investigations of phase composition of the alloy. During crystallization process mechanical mixing of alloy was applied in order to improve uniform distribution of elements in the sample. X-ray powder diffraction (INEL diffractometer), selected area electron diffraction, X-ray microprobe and differential thermal analysis were employed during investigation. Our experimental work had three aspects. The main task was concerned on the phase composition investigations. We have confirmed existence of the cubic phase however aperiodic phase was not found. The crystallized material had porous character and inside pours faceted crystal forms were observed. The polygonal single crystals appeared to be Mg crystals. In addition we have found composite character of the alloy. Inside of the parent phase growth of colonies of Zn faceted whiskers took place. The whiskers appeared when parent phase was dissolved and removed. Zn whiskers had hexagonal cross section and [0001] growth direction. They exhibited high degree of perfection.

P07.23.001 FURTHER DEVELOPMENTS OF THE BILBAO CRYSTALLOGRAPHIC SERVER. E. Kroumova, J.M. Pérez-Mato, S. Ivantchev, G. Madariaga, Departamentos de Física de la Materia Condensada y Física Aplicada II, Universidad del País Vasco, Apdo. 644, 48080 Bilbao, Spain, and M.I. Aroyo, A.K. Kirov, Condensed Matter Physics Dept, Sofia University, 1164 Sofia, Bulgaria, and H. Wondratschek, Institut für Kristallographie der Universität Karlsruhe, D-76128 Karlsruhe, Germany

The Bilbao Crystallographic Server (**http://www.cryst.ehu.es**) has already been under use for more than a year [1]. The aim of this contribution is to report on the recent advances in the development of the server.

The main kernel contains a set of databases which include: (i) data from the space-group tables of *International Tables for Crystallography*, vol. A, (ii) data from the subgroup tables of *International Tables for Crystallography*, vol. A1. Recently, we have added a database of incommensurate structures with an interface which permits simple queries and input of new structures. In addition to the programs already reported [1], we have included a pseudosymmetry check program which detects for a given crystal structure any kind of crystallographic pseudosymmetry within a chosen tolerance factor [2]. We have also started the development of the shell on tools using representation theory of space groups. The server now offers access to (i) the program KAREP for constructing little-group and full-group representations of space groups, and (ii) the program CORREL for investigating the correlations between irreducible representations of group-subgroup related space groups.

P07.23.002 INTERACTIVE MOLECULAR STRUCTURE DATABASE ON INTRANET. Fusen Han, Structure, Analytical and Medicinal Chemistry, Pharmacia & Upjohn Inc., 301 Henrietta Street, Kalamazoo, MI 49007, USA

With simple *.html and *.pdb files, crystal structures can be displayed via the "Chime[1]" plug-in software on a internet home page. However, the functions of Chime are limited. The new Script Technology, especially the new released VBScript[2] plus Internet Explorer[2] 4.0, makes it possible to develop more sophisticated molecule displaying software on the internet without the limit of a plug-in.

We have set up our internal small molecule structure database on our company Intranet. It is the most efficient method to deliver our crystal structure results to our research community worldwide. Two versions of this database are being tested: one uses Chime only and the other one uses VBScript plus Chime. The second version has more functions and is much more flexible to manipulate with VBScript. The current VBScript version contains most of the ActiveX[2] Controls used in Visual Basic[2] 5.0. In addition, FileSystemObject[2] is necessary for manipulating data files. With these tools, accessing data files and creating graphic user interfaces on the internet becomes very simple and user friendly.

In this poster, the database components, user interfaces, control elements, script code and sample molecule structures are presented and discussed.

It is also possible to protect the script source code by encoding the script file using Microsoft Script Encoder[2].

P07.23.003 CRYSTMET: AN INTEGRATED STRUCTURE AND POWDER DATABASE FOR INTERMETALLICS. Peter S. White, Department of Chemistry, University of North Carolina at Chapel Hill, NC, USA, John R. Rodgers, Toth Information Systems Inc, 2045 Quincy Avenue, Gloucester, ON, Canada and Yvon Le Page, National Research Council of Canada, Ottawa, ON, Canada.

The intermetallics database, *CRYSTMET*, is supported and being actively developed by Toth Information Systems Inc. The database was originally developed by the National Research Council of Canada as part of the CISTI numerical databases. This paper will describe the contents of the database, its transfer to a relational database structure, its extension to support X-ray and neutron powder pattern matching, and the software currently being developed for searching and analyzing results.

The *CRYSTMET* database consists of a number of records, which contain bibliographic, structural and limited physical property information about each entry. About 50% of the current entries include atomic coordinates. Within the relational database the data is stored in a set of tables designed to optimize search and retrieval operations.

The search program provides the user with a simple, intuitive graphical interface to develop queries. A variety of query types are available, including chemical composition, symmetry and structure type, and unit cell dimensions In addition, entries with coordinates can be searched using tables of computed powder patterns. Entries which do not include atomic coordinates are optionally searched on tables of valid d-spacings.

The results of such queries are stored as sets of entries that can be edited or logically combined with other result sets. A single entry can be listed in detail and functions are available to generate a structural diagram, generate and display a powder pattern, and compute various geometrical quantities. Facilities are also provided to graphically examine the distribution of a property over an entire set of entries.

The database and search software is currently available from Toth for use on PCs running Windows 95, 98 or NT.

P07.23.004 A NEW SEARCH/MATCH SYSTEM-NK-7. Yong Bing Peng [1], Lian Hu Wei, Ron Chen Yuan, Yuan Qiao, Shao Fan Lin [2], Yu Hu Xu [3], [1] Institute of Elemento-organic Chemistry, NanKai University, TianJin, 300071(China), [2] Central Laboratory, NanKai University, TianJin, 300071(China), [3] Guangdong Part Time University of Science and Technology Guangzhou 510090 P.R.China

In this article, a new method for identifying components in crystalline mixtures from their X-ray powder diffraction data is presented. It can be run in Windows-95 and Windows-98. The database comes from the powder diffraction files (PDF) provided by the JCPDS-International Centre for Diffraction Data.

It has been demonstrated that the method can give the definite phase compositions of the unknown multiphase mixtures rapidly and correctly. This method uses the weight factor for each diffraction peak as a criterion, and can not only give a list possible phases but also the definite components of the unknown sample by a simulation process. Actual samples included organic samples have been tested with high performance. The key points in this system are:

1. The TMIP (three most intensive peaks) filtering: Compare the sample PDF data with each standard pattern in the database to see if its TMIP exist in the sample pattern. If yes, then keep this phase as a candidate.

2. Element filtering by comparing the elemental composition (EC) of each candidate with the sample of the Elements existed in candidate include in sample. If yes then it was conceded as possible phase existed in sample (Selected Phases).

3. Calculation the value FOP (Factor Of Possibly) of Selected Phases: The value FOP of each Selected Phases is then calculated and a list is printed according to the descending order of the FOP. The phases with higher FOP have more possibility existed in the experimental pattern.

Similar with these first three steps, all the existing methods can give an ordered list of 10 to 50 phases which may be present in the sample but we have not found any previous method which can give a definite answer. Our program tries to get the definite answer after following steps.

4. Pattern Simulation: The program uses those Selected Phases as the basic units to simulate the sample pattern with various combinations. If all the components of the sample are within the Selected Phases, then there must be a case in the complete combinations is the real components of sample.

5. Evaluation of the simulated patterns:

To evaluate each simulated pattern, the program calculates the value FOS (Factor of similarity) according to: A. The EC of the simulated pattern should be the same as that of the sample. Otherwise the value of FEC (Factor of EC) should be reduced. B. Compare the peaks and the intensities between simulated pattern and sample pattern to calculate the value SPI (Similarity of Peaks and Intensities) C. Calculate the FOS according to the value FEC and SPI. The components of the simulated pattern, which has highest value FOS, would be the components of sample.

P07.23.006 STATISTICAL ANALYSIS OF DISTRIBUTION OF CSD STRUCTURES BY SPACE GROUPS AND BY STRUCTURAL CLASSES. Oleynikov P.N., Zorky P.M. Chemistry Department, MSU, Russia

A statistical analysis of the distribution of ~ 163000 crystal structures by space groups (SG) and by structural classes (SC) has been carried out. These structures correspond to 181309 entries contained in Cambridge Structural Database (April 1998). It has been discovered that this distribution is substantially different for diverse classes of chemical substances. Typical features of the studied distributions emerge when the set of CSD structures is subdivided into *crystal chemistry classes*.

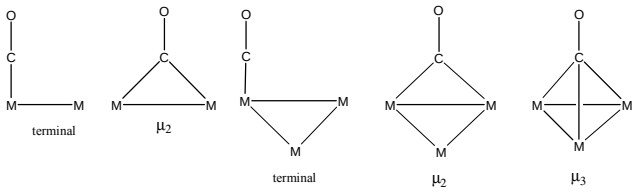
As crystal chemistry classes the number of representatives in CSD of which is sufficient for revealing statistical regularities we considered: 1) homomolecular crystals consisting of chemically identical molecules (n = 1), 2) heteromolecular crystals containing molecules (particles) of two kinds (n = 2), among the latter we particularly distinguished salts, molecular complexes, solvates and hydrates. For all the named groups of substances we separately studied: 1) organic substances, which contain only organogenic elements, 2) other CSD structures (we call them non-organic).

Two types of SG distributions have been revealed for organic substances: the first is characteristic of homomolecular substances and salts, the second, of molecular complexes and solvates. The presence of these two types is not so pronounced among non-organic substances, the considerable decrease of the contribution of chiral groups ($P2_12_12_1$, $P2_1$ etc.) as compared with organic crystals being found in all crystal chemistry classes.

The distinction between crystal chemistry classes manifests itself even more vividly in SC distributions (SC is SG plus a list of the orbits occupied by particles). The most impressive regularity is the sharp distinction between some SC popularities for organic and non-organic crystals.

P07.23.007 STRUCTURAL SYSTEMATICS – A STUDY OF CARBONYL MIGRATION ON M_2 and M_3 UNITS. Amy L. Gillon and A. Guy Orpen, School of Chemistry, University of Bristol, Cantock's Close, Bristol, BS8 1TS, UK.

Data were retrieved from the Cambridge Structural Database from crystal structures containing suitable geometric data for complexes containing the metal-metal bonded fragments $M_2(CO)$ and $M_3(CO)$ (where M = Fe, Ru, Os, Co, Rh, Ir).



These data were analysed, using the structure correlation method[1], to examine the locations of the carbonyl ligands in all positions from terminal to bridging, to triply bridging (in the case of $M_3(CO)$ fragments). The dimetal case shows a clear continuum of points through the two dimensional plot of metal carbon distances, in agreement with previous studies[2,3]. The distribution of points may be taken to indicate the reaction pathway for bridge-terminal exchange in polynuclear metal carbonyls. Similarly the data obtained for the trimetal case allows the examination of the distribution of carbonyl geometries across the triangular metal array. The distribution of points shows pathways linking the terminal μ_2 and μ_3 carbonyl geometries and may indicate preferred pathways for the movement of a carbonyl across a close packed metal array.

P07.23.008 CHLORIDE, ORGANOCHLORINE, AND METAL CHLORIDE HYDROGEN BOND ACCEPTORS. Owen D. Hayward and A. Guy Orpen, School of Chemistry, University of Bristol, Cantock's Close, Bristol. BS8 1TS. UK.

The design and synthesis of specific structural aggregates in the solid state often relies on a knowledge of robust hydrogen bonding interactions that can be used to "bind" together individual molecular building blocks[1]. Hydrogen bonding is one of the most significant forces in crystal packing with even C-H hydrogen bonds playing an important role in the patterns formed by molecules in the crystalline state. The chloride acceptor has been found to play an important role in crystal packing, and in recent years metal chlorides have also been identified as having a potentially significant effect on the packing of many structures.

Recent advances in the 3D searching capabilities of the Cambridge Structural Database (CSD)[2] have led to a large number of geometrical studies of various hydrogen bonding donors and acceptors. However there has been relatively little analysis of the donor co-ordination numbers of acceptors.

The co-ordination of the hydrogen bonding acceptors chloride (Cl^-), metal chloride (M-Cl) and organic chlorine (C-Cl) will be discussed and data on the relative frequency of hydrogen bonding occurring will be presented. O-H, N-H and C-H will be considered as potential donor systems. Unique examples will be highlighted and the more robust interactions will be portrayed as potential sythons for crystal engineering.

P07.23.009 PSEUDOSYMMETRICAL ORTHOGONAL LAYERS IN TRICLINIC ORGANIC CRYSTALS Muydinov R.Yu., Zorky P.M., Department of Chemistry, Moscow State University, Leninskie Gory, Moscow 119899, Russia

In most organic homomolecular crystals molecules occupy only one orbit (k = 1), i.e. an asymmetric part of the cell contains only one molecule. However, in ~10% of such crystals k>1 (k = 2 in ~7% of them). If crystals with k = 1 are considered to be normal, the formation of a structure with k>1 requires an interpretation: in each case it is necessary to explain why it is just this structure that arises.

The formation of polysystem (k>1) structures is certainly caused by different reasons. In the study of structures belonging to class $P\bar{1}$, Z=4 (1^2) we have found one of the mechanisms leading to the arising of polysystem structures: it is the formation of pseudosymmetrical orthogonal layers the superposition of which causes the disturbance of the potential function and a triclinic crystal is formed. Examples are crystals of MNPPRB and MBSIND (see CSD). In the former one can see clearly defined chains with local pseudosymmetry P_c c, in the latter, $P_c 2_1$. The chains are superimposed with inversion centers; and in both cases layers $P_l 2_1/c$ arise. A superposition of such layers commonly leads to class $P_l 2_1/c$, Z=4 (1). In the considered cases, however, the layers appear to be too rigid (unadaptable). As a result there arise a triclinic bisystem crystal in which the given symmetry of layers is present as local pseudosymmetry.

In CSD we have found 1246 organic homomolecular crystals of class $P\bar{1}$, Z=4 (1^2). In 299 of them (24%) there are orthogonal two-dimensional sublattices, which seems to indicate the presence of pseudosymmetrical orthogonal layers.

P07.23.010 INVESTIGATION OF INTER CONVERSION PATHWAYS BETWEEN METAL COORDINATION SPHERE GEOMETRY FROM CRYSTALLOGRAPHIC DATA. Jing Wen Yao and Judith A. K. Howard, Department of Chemistry, University of Durham, Durham, DH1 3LE, UK and Frank H. Allen, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK.

A useful method to solve the problem and complexity in detecting geometrical preference of metal 7-coordiantion sphere by using the CSD data has been given[1]. A calculated Euclidean dissimilarity between the idealized metal-ligand valence angles and observed angles provides a numerical measurement, from which geometrical deviation of an observed structure from the standard polyhedra can be obtained.

This method can be also used generally in lower coordination numbers (n = 3-6). The scatterplots of the two specified discrepancy indices [$R_c(x)$] reveal not only geometry preference to the representative polyhedra in these coordination species but also interconversion pathways between the reference geometries.

A preliminary work has been carried out to investigate a possible reaction pathway from 6+1 to 7 coordination from the structural data. An extra ligand is supposed to attack to the central metal atom in a 6-coordination octahedral sphere and form a 7-coordination sphere[2]. The preferential direction of the attacking ligand has been observed and compared with 7-coordination species. It can be seen that all attacks are either from a triangular face of octahedron to form COC/CTP or from an edge of the square plane of octahedron to form a PBP. All the observed points fall into the range between these two extreme cases. This means that it is possible to use these data to further explore the relationships from 6+1 coordination leading to 7-coordination by geometrical similarity.

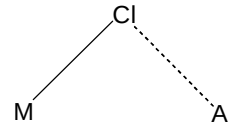
P07.23.011 THE AGGREGATION OF METAL COMPLEXES BY M-μ–Cl INTERACTIONS. Kirsty M. Anderson and A. Guy Orpen, School of Chemistry, University of Bristol, Cantock's Close, Bristol, BS8 1TS. UK.

A large number of solid state structures are known in which metal bound chloride forms secondary interactions though hydrogen bonding or by lone pair donation to another metal. These interactions play an important role in the aggregation of metal complexes with the characterisation and understanding of the interactions being an important aspect of the developing field of crystal engineering.

The interactions between the metal bound chloride and its surrounding atoms can be described using a variety of structural parameters. Using the Cambridge Structural Database (CSD) bond lengths and angles for the following system were extracted and analysed.

Where M = Group 10 & 11 metal
A = M, H-D, Tr
and D = N or O



The dependence of these parameters on the nature of M and A (eg. d-electron count, formal oxidation state, the number of bridging interactions formed per M and A) are discussed and interesting examples highlighted.

The use of bridging chlorides, to provide solutions to crystal engineering problems involving these elements, and also as robust synthons for crystal engineering will be discussed.

P07.23.012 GRAPH SET HYDROGEN BONDING ANALYSIS AND CRYSTAL STRUCTURE PREDICTION OF OXIMES. L.C. Kerr, P.R. Raithby [1], W.D.S. Motherwell, G.P. Shields [2], [1] Department of Chemistry, University of Cambridge, Cambridge CB2 1EW, [2] Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ.

A graph set analysis[1] of the hydrogen bonding of oximes in the Cambridge Structural Database has been performed, showing that when there is only one oxime group in each molecule, they hydrogen bond preferentially in a dimeric structure. In certain cases, however, chain-type structures have been found. This difference is thought to be due to steric factors. In order to verify this, a new crystal structure prediction program, Rancel[2], was used to predict the packing for some of the oximes. The results tend to predict the packing with some success and also to confirm the potential of the Rancel program in structure prediction.

P07.23.014 PACKSTAR: A CRYSTAL STRUCTURE PREDICTION PROGRAM. J.P.M. Lommerse W.D.S. Motherwell Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, United Kingdom

An ab initio method is presented to predict crystal structures of small organic molecules. In contrast to most methods

in this field, the program is not based on calculation of energies, but uses data from the Cambridge Structural Database (CSD) [1]. Stochastic methods (Genetic Algorithms (GA) and Simulated Annealing (SA)) are applied to search for minima in a given spacegroup. The cost function for the GA/SA is calculated from a composite crystal field environment. This field is built up from small functional groups that are constituents of the molecule of interest. From the CSD distributions of one group around another can be extracted, transformed into density maps and combined to form a crystal field environment around a molecule [2]. Information about directionality, such as a hydroxyl group pointing toward an acceptor, is preserved. In the calculated crystal structure, the fit of all functional groups in the crystal field environment determines the cost for the GA/SA. It is assumed that the experimental structure has lowest cost, which should represent the best fit with the CSD. The accuracy of the method largely depends on the quantity of data available in the CSD. A grid is used to store values of the density maps around the molecule. The grid size typically is 0.5-0.8 Angstrom. This determines the accuracy of the method, in terms of cell dimensions and orientation and position of the molecules in the cell. Therefore, a subsequent minimisation using empirical energy functions is applied to obtain the final crystal structure [3].

P07.23.015 CRYSTAL STRUCTURE PREDICTION USING ATOM CONTACT DISTRIBUTIONS FROM THE CAMBRIDGE STRUCTURAL DATABASE. Sam Motherwell Cambridge Crystallographic Data Centre, 12 Union Rd., Cambridge CB2 1EZ

A methodology has been developed for calculation of probable crystal structures based on the intermolecular atom-atom distances in the Cambridge Structural Database (CSD). GA methods have been used to find calculated crystal structures using rigid molecular models in common space groups. A fitness function is calculated which is a minimum when the calculated distance frequency distribution agrees best with the CSD for each atom-type in the molecule. All contacts are counted to each atom, giving a frequency distribution for a normalised distance D = Rij - Rv, where Rij is the distance between atoms i and j, and Rv is the sum of the van der Waals radii. The method makes no assumptions about energy, but seeks to reproduce the CSD frequencies characteristic of a selected set of similar molecules in the CSD. Extra fitting information can be given for patterns of close contact D < Rv, where a sample of chemically similar CSD molecules shows a good probability of occurrence, H-bonds being a typical example. These expectation values can be set even though we have no theoretical explanation of such patterns, and may often have kinetic reasons for formation [1]. It is interesting that the method is often successful even though the fitness criteria are essentially non-directional, but based only on atom pair distributions. The results of a program, RANCEL [2], are given showing successes and failures of the method to a variety of chemical species.

P07.23.016 THE GEOMETRY OF THE TETRAETHYLAMMONIUM CATION. Joan Halfpenny, Department of Chemistry and Physics, Nottingham Trent University, Clifton Lane, Nottingham, NG11 8NS, UK.

The structure of the ionic compound bis(tetraethylammonium) dichlorodiisothiocyanatodimethylstannate(IV) determined by the author contains two crystallographically non-equivalent tetraethylammonium groups of differing geometries. When viewed along the four-fold inversion axis of symmetry it is apparent that one tetraethylammonium cation has the ethyl groups arranged 'linearly' and the other in a 'propeller' shape around the tetrahedrally-substituted nitrogen. The latter geometry is slightly more efficient at space filling. There are no unexpected intermolecular contacts, inter- or intra-molecular interactions affecting one cation more than the other and therefore the fact that both species coexist in this particular structure is of considerable interest. The results of energy minimisation calculations on the relative stabilities of the 'linear' and 'propeller' tetrahedral geometries will be presented, together with statistics derived from a survey of more than 1500 compounds containing the tetraethylammonium cation in the Cambridge Crystallographic Database. Approximately half of these compound formulae contain two or more tetraethylammonium cations although in many structures the groups are crystallographically equivalent. The relative incidence of each type of geometry and its relation to the coordination environment of the cation will be discussed.

Crystal data. $[(C_2H_5)N^+]_2$ $[SnCl_2(CH_3)_2(NCS)_2]^{2-}$, monoclinic, $P2_1/c$, Z = 4, a = 13.750(10), b = 17.86(2), c = 13.420(10) Å, β = 113.90(10)°, V = 3013(5) Å^3, μ = 1.177 mm^{-1}, D_x = 1.315 Mg m^{-3}, R = 0.0527, *w*R = 0.1446 for 3800 unique reflections recorded on a STOE Stadi-2 2-circle diffractometer with MoK_α radiation, λ = 0.7107 Å, room temperature. N-C bond lengths in tetraethylammonium ions: 'linear' arrangement 1.498(8), 1.513(8), 1.516(8), 1.533(8) Å, 'propeller' arrangement 1.505(8), 1.512(8), 1.518(7), 1.525(8) Å.

P07.23.017 STRUCTURAL STUDIES OF DIRUTHENIUM COMPLEXES-A LOCAL DATABASE STUDY. J.P.H. Charmant, S.A.R. Knox and A.G. Orpen, School of Chemistry, University of Bristol, Cantock's Close, Bristol BS8 1TS, UK.

Recent advances in X-ray diffraction instrumentation have led to a substantial increase in the speed of a typical single crystal structure determination. This inevitably leads to the publication of only those results considered to be of particular importance.

In Bristol, a large number of diruthenium cyclopentadienyl complexes have been characterised by single-crystal X-ray diffraction studies. Many of these results have been published1 but many more have not. We have recently started building a local database of unpublished structural information using diruthenium cyclopentadienyl complexes as a starting point. The database has been built using PreQUEST software supplied as part of the Cambridge Structural Database (CSD) System.

We wish to use this local database to study metal-carbon interactions that are fundamental to many organometallic processes. Our initial work is an investigation of carbon monoxide bonding modes at diruthenium centres. We have compared the results obtained from our local database of unpublished structure determination data with studies carried out on published data contained in the CSD. Conclusions are drawn about carbonyl migration pathways at a dimetal centre and the reliability of local data sets compared to the more substantial data set of the CSD.

P07.23.021 APPLICATION OF NEW METHODS FOR CRYSTALLOGRAPHIC DATA QUALITY CONTROL. Y. Kotliarov, Institute of Inorganic Chemistry, SB RAS, Novosibirsk 630090, Russia, and S. Iwata, Research into Artifacts, Center for Engineering, the University of Tokyo, Tokyo 153, Japan.

Two methods for crystallographic data quality control have been developed and applied for use with Inorganic Crystal Structure Database. Those methods can detect data where individual atoms or structural fragments are located too far from each other, forming impossibly large gaps.

The first method separates atoms in a unit cell into sets of atoms lying in planar parallel **layers**, perpendicular to some direction: for example, one of the main coordinate axes. If a distance between adjacent layers longer than some critical distance is found, one can conclude that there is no connection between those layers, and the structure can be said to be disconnected.

The layer method is fast and easy to apply. It is especially reliable for actually layered structures. However, it is only a rough evaluation of gaps in structure, because interlayer distances are most commonly shorter than interatomic distances and do not reflect the real connectivity between atoms. The second method--with application of **graph theory**--does not have those disadvantages.

The crystal structure can be described as a graph with atoms as vertices and bonds as edges. To make the graph finite, only atoms inside the unit cell are included in it. Although such a graph loses the space arrangement of atoms and symmetry elements, it can mathematically describe the relationship between atoms in terms of their connections. Two atoms are considered as connected if the distance between them is shorter than some critical distance, and the connectivity matrix can be constructed. Then the connectivity test on a structure graph (whether the structure graph is connected or not) can help to reveal disconnected structures.

Both methods have been applied to data from ICSD and have helped to detect several erroneous disconnected structures, which the conventional test has failed to do.

P07.23.022 ICSD-FOR-WWW, A DEMONSTRATION OF THE LATEST FEATURES, INCLUDING BOND VALENCE. Alan Hewat, Institut Laue-Langevin, BP 156X, Grenoble 38042, FRANCE.

A demonstration of ICSD-for-WWW will show how easy it is to access the almost 50,000 structures in the Inorganic Crystal Structure Database via the WWW, or at least a local server (eg see http://barns.ill.fr/dif/icsd/). The latest features include automatic calculation of bond-valence sums as a check on the structure during preparations for visualisation using VRML.

The WWW interface looks the same on any computer, Windows-PC, Macintosh or Unix workstation. A selection of structures is obtained by entering the usual search criteria, then the search can be narrowed with additional criteria. The resulting entries can be printed out in standard reference format for cut-and-paste into manuscripts, or in EndNote bibliographic format. They can be ordered according to date, formula, author, space group or mineral name for further processing.

Individual entries can be compared, listed in full, and used to generate X-ray or neutron powder diffraction patterns, with peaks automatically indexed. Finally the 3D structure can be drawn, zoomed and rotated, with the usual space-filling, ball-and-stick or co-ordination polyhedrae models available.

The latest features include automatic calculation of Brown-Shannon valence sums to check the chemical validity of the structure, the illustration of sites of different valence state with different colours, the drawing of mixed-atom polyhedrae such as in oxy-chlorides etc.

ICSD-for-WWW servers have already been set up in France, Germany, the UK, USA and Japan, the software is distributed free of charge for a limited demonstration data-set, and also with the licence for the full ICSD data-set from FIZ Karlsruhe.

P07.23.024 STOCHASTIC MODELING OF THE EVOLUTION OF PROTEIN SEQUENCE LENGTH IN GENOMES: PREFERRED DOMAIN SIZES. R. Jain and S. Ramakumar, Physics Department, Indian Institute of Science, Bangalore 560012, India, and Bioinformatics Centre, Indian Institute of Science, Bangalore 560012, India.

We have proposed for the first time a stochastic model, which explains the protein sequence length distribution in all the fully sequenced microbial genomes. The stochastic model is universal since it has been possible to explain the overall features of the length distribution of all the genomes in terms of it. Analysis of protein sequence length distribution for 17 organisms (12 bacteria, 4 archaea and 1 eukaryote) yields a log-normal distribution. According to the stochastic model, mutation can be considered to be a random multiplicative process that takes place in discrete steps. Then, the length of the protein S_t at time t, is related to its length $S_{t+\Delta t}$ at time $t+\Delta t$ by: $S_{t+\Delta t} = \varepsilon_t S_t$. Here ε_t is a random number slightly different from one. $\varepsilon_t < 1$ corresponds to a decrease in the protein length due to deletion of amino acids, $\varepsilon_t > 1$ corresponds to increase in length due to addition of amino acids, and $\varepsilon_t = 1$ corresponds to no change or to point mutation. Thus the length S_N at the Nth level of mutation is given by the product of N random variables: $S_N = S_0 \prod \varepsilon j$ where the product is over j from 0 to N-1. Hence, according to Central Limit Theorem, the logarithm of the protein length distribution is a Gaussian. Therefore the distribution is a log-normal. Peaks due to the clustering of proteins characterize the fine structure of the distributions. These peak regions probably contain genome specific proteins, which could therefore be potential targets for structure determination for purpose of identification of novel folds as in structural genomics project. Fourier analysis of the distributions reveals an underlying periodicity. The periodicity in the protein length distribution implies domain size preference for that organism. The preferred domain size is found to be genome specific. This work is important as it offers opportunities to identify preferred domain size and provides a model to mimic evolution.

R. Jain thanks CSIR (India) for a scholarship.

P07.23.025 SBDBASE: A DATABASE OF COMPUTER GENERATED STRUCTURE MODELS OF TARGET PROTEINS. M. Prabhakaran, S. E. Mylvaganam, G. Raghunathan, M. D. Shenderovich, C. L. Fisher and K. Ramnarayan. Structural Bioinformatics Inc., Dept. of Structural Sciences, 10929 Technology Place, San Diego, CA 92127 USA.

Using existing structural and sequence information, we have developed the Structural Bioinformatics dataBase (SBdBase) of computer-generated protein structure models directly from sequence. Our computational approach in protein modelling from sequence relies on the concept that proteins within a superfamily of similar sequences share common three-dimensional folds and functions. At Structural Bioinformatics Inc. our focus is to obtain three-dimensional representations of proteins for which structures are unavailable but which have sequence similarities with existing NMR and X-ray crystal structures. Additional computer schemes are also applied to define the proteins' detailed structural features, such as active sites, surface chemistry and topology. In the absence of precise three-dimensional structures, the SBdBase provides structural information for a number of human sequences and other protein targets that are potential candidates for drug design and protein engineering.

P09.23.001 JOINT REFINEMENT OF A PROTEIN STRUCTURE AGAINST NMR AND X-RAY DATA. M.L. Raves[1], J.F. Doreleijers[1], H. Vis[1], C.E. Vorgias[2], Z. Dauter[3], K.S. Wilson[4] and R. Kaptein[1], [1] Bijvoet Center for Biomolecular Research, Utrecht University, The Netherlands, [2] EMBL, Hamburg, Germany, [3] Brookhaven National Lab., USA, [4] Protein Structure Group, York University, UK.

Joint refinement, *i.e.* the simultaneous refinement of a structure agains NMR and X-ray data [1], was done in order to investigate the compatibility of the two data sets. Wherever a conflict was found, attempts have been made to determine whether it arose from misinterpretation of the experimental data or from real differences of the protein conformation in solution *vs.* that in the crystal.

The DNA-binding protein HU was taken as a test-case. Its structure consists of a rigid core and two flexible 'arms' and was solved independently by NMR [2] and by X-ray crystallogaphy [3]. The joint refinement procedure started with an unbiased random structure, which was folded using the NMR restraints and then placed in the crystallographic unit cell by molecular replacement. Important differences in main-chain conformations and secondary structure were identified and investigated.

24. INDUSTRIAL CRYSTALLOGRAPHY

P05.24.001 DETERMINATION OF RETAINED AUSTENITE IN AUSTEMPERED VERMICULAR IRON BY RIETVELD ANALYSIS. R.L. Mannheim and J.L. Garin, Department of Metallurgical Engineering, Universidad de Santiago de Chile, Casilla 10233, Santiago, Chile.

Austempered vermicular iron (AVI) alloys have received much attention because of their interesting mechanical properties and applications in the automotive and mining industries.

During heat treatment of AVI alloys variable amounts of austenite are retained in the ferritic matrix, giving place to the so-called ausferritic microstructure. Since the formation of the austenitic phase strongly affects the mechanical properties of the material, a complete characterization of a given alloy must include the relative amount of austenite in the matrix.

Owing to the fact that the heat treatments of this kind of alloys yield nearly complete resolution of the (110) and (111) reflections of the alpha and gamma phases respectively, a Rietveld analysis was conveniently carried out on the material to determine the content of retained austenite. A series of samples was prepared by austenizing at 900 °C and austempering in the range of 280 - 410 °C to yield various amounts of austenite from 4 to 40%. The room temperature data collection for each specimen was carried out over the range of 20 - 90° (2θ), with 3500 step intensities, using Cu Kα radiation and grapite monochromator. The X-ray analysis was performed assuming asymmetric Pearson VII profiles for all reflections. The refinement cycles were based upon the variation of isotropic thermal parameters, scale factors, preferred orientation coefficients, surface roughness, background polynomial coefficients, sample transparency and displacement and so on.

The described procedure based upon using of the Rietveld software proved to be very reliable, mainly when the effects of preferred orientations on the intensities have to be corrected for.

P05.24.002 SYNTHESIS AND CHARACTERIZATION OF NANOCRYSTALLINE Ni_3Al BY CHEMICAL ROUTE. S.K. Pradhan [1], A. Datta [2], M. Pal [3], P. Bose [1], D. Chakravorty [3], [1] Department of Physics, The University of Burdwan, Golapbag, Burdwan -713104, [2] Institute of Atomic and Molecular Science, Academia Sinica, P.O. Box 23-166, Taipei, Taiwan 106, [3] Indian Association for the Cultivation of Science, Jadavpur, Calcutta 700 032, India.

Both ordered and disordered alloys of Ni_3Al in the nanocrystalline form were synthesized by a sol-gel technique followed by hot pressing at temperatures in the range 873 to 1173 K. The crystallite size, r.m.s. strain and the dislocation density were determined by a modified Rietveld method and Warren-Averbach's peak broadening analysis. For most of the specimens the particle size and r.m.s. strain were found to be anisotropic in nature. The average diameters varied from 10 to 30 nm depending on the hot pressing conditions.

P05.24.003 SMALL ANGLE NEUTRON SCATTERING AS A POWERFUL TOOL TO INVESTIGATE PRECIPITATES IN SUPER-ALLOYS. R. Gilles[1], P. Strunz[2], D. Mukherji[3], A. Wiedenmann[2] and H. Fuess[1]. [1] University of Technology Darmstadt, Petersenstr. 23, 64287 Darmstadt, Germany, [2] Hahn-Meitner-Institut, Glienicker Str. 100, 14109 Berlin and [3] University of Technology Braunschweig, Langer Kamp 8, 38106 Braunschweig, Germany.

Single-crystal nickel-base superalloys, recently developed for blade applications in land-based gas turbines, were characterized using the Small Angle Neutron Scattering (SANS) instrument V4 in HMI Berlin. Superalloys are strengthened by the γ′ precipitates ($L1_2$ structure), which are coherently embedded in a single-crystal γ matrix of nickel solid-solution (fcc). It is well known that the precipitate morphology, their distribution in the matrix and their volume fraction strongly influence the strength of the alloys.

Specimens heat treated to produce a homogeneous distribution of γ′ precipitates of different sizes were investigated by detecting 2D scattering patterns as a function of orientation of the specimen. Analysis of the data resulted in values of size, interparticle distance, volume fraction and orientation distribution of precipitates. These parameters describe well the morphology of the precipitates. To determine the individual microstructural characteristics, a comparison of iso-intensity profiles of measured and simulated 2D curves was performed on the basis of a microstructural model of the superalloy. Supplementary measurements with TEM, SEM and XRD completed and confirmed our SANS results.

P05.24.004 STRAIN DISTRIBUTION IN NANOCRYSTALLINE TITANIUM. Partha Chatterjee , S. P. Sen Gupta, Department of Materials Science, IACS, Jadavpur, Calcutta-700032, India

An X-ray line broadening study of ball-milled Titanium metal is presented. A profile fitting methodology with a Pseudo-voigt profile shape function is adopted. Fourier line shape study for both the fault-affected and fault-unaffected reflections are carried out. It is found that ball-milling results in the formation of nanocrystalline Ti phase. The values of the crystallite size range from 11-13 nm for different crystallographic direction. The values of rms microstrains are of the order of 0.2-0.3 %. The variation of the rms microstrain with coherence lengths in terms of local strain and its derivatives indicate that the strains are non-uniform for small column lengths and this is indicative of strongly localized strain fields in the crystallite interfaces. The present analysis could not bring out the presence of stacking faults in the nanocrystalline region.

P05.24.005 CRYSTAL STRUCTURE OF DISORDERED MAGNESIUM TITANATES IN CONCENTRATION, TEMPERATURE AND TIME DIMENSIONS. G. Kimmel,[1] J. Zabicky,[1] and P. Arigur.[2] Ben-Gurion University of the Negev, POB 653, Beer-Sheva 84105, Israel;[1] and Western Michigan University, Kalamazoo, MI 49008, USA.[2]

Three equilibrium crystalline phases are known for the MgO-TiO_2 system: Mg_2TiO_4 (qandilite), $MgTiO_3$ (geikielite) and $MgTi_2O_5$ (karrooite), that are isomorphous with inverse spinel, ilmenite and disordered brookites, respectively. Qandilite and karrooite are high temperature phases which can retain the H.T. structure at room temperature on rapid cooling. After prolongued thermal annealing, a cubic to tetragonal phase transformation of qandilite and modifications of the unit cell parameters of geikielite and karrooite have been reported.

In this work all the precursors were prepared by the sol-gel method. Most samples were studied by XRPD, but some of them were also investigated by neutron diffraction. The following results were obtained by various experimental procedures: (a) Energetic milling of separately prepared precursors of MgO and TiO_2 for long periods (up to 24 h) was insufficient to produce a

unique nanocrystalline magnesium titanate phase, corresponding to the Mg:Ti ratio of the precursors; instead, mixtures of geikielite, qandilite, and periclase pointed to incomplete thermal annealig and states far from equilibrium. (b) Coprecipitated precursors with a wide range of Mg:Ti atomic ratios (x:y), yielded nanocrystalline powders of composition $xMgO.yTiO_2$, after a short (2-4 h) primary heat treatment at 600°C. The diffractgrams of nonstoichiometric qandilite were severely broadened, but the cell parameters were left unchanged. Atomic disordering of the inverse spinel nanophase took place for Mg:Ti atomic ratios from 2:1 to about 1.3:1. Deviation from stoichiometry of karrooite (from 1:2 to about1:1.5) caused modification of the unit cell parameters. (c) The products of item (b) are metastable. Secondary heating at 800°C returns the system into equilibrium within several hours. (d) The precursors of item (b) were rapidly heated to a constant temperature in the 550 to 1300°C range, for a real-time kinetical study by HTXRD.

P05.24.006 CHARACTERISATION OF PMA COATED NANO-CRYSTALLINE γ-Fe_2O_3. M. Hagelstein, E. Pellegrin, S. Doyle, H. O. Moser, Forschungszentrum Karlsruhe, PEA, P. O. Box 3640, D-76021 Karlsruhe, Germany, and J. Fuchs, D. Vollath, D. V. Szabó, Forschungszentrum Karlsruhe, IMF-III, P. O. Box 3640, D-76021 Karlsruhe, Germany, and C. Ferrero, A. Fitch, European Synchrotron Radiation Facility, B. P. 220, F–38043 Grenoble Cedex, France

A new type of magnetic nanocomposites made of coated nanoparticles for applications has been synthesised using the microwave plasma process [1]. Due to their small size, PMA coated nanoparticles of γ-Fe_2O_3 show superparamagnetism. Transmission electron diffraction and Mößbauer-spectroscopy indicate structural disorder. This might explain the small saturation magnetisation found in this material. Sophisticated analytical techniques using synchrotron radiation, like x-ray powder diffraction, x-ray absorption spectroscopy and soft x-ray magnetic circular dichroism have been applied for additional characterisation of the chemical, structural and magnetic properties of the material.

A lower particle size limit of 4 nm was determined by X-ray powder diffraction. The experimental powder pattern was Rietveld refined using the magnetite structure, although it was complicated due to the presence of two crystalline phases. The Fe-O and Fe-Fe distances and co-ordination numbers have been derived from x-ray absorption fine structure spectra at the Fe K edge. Four shells from 0.189 nm to 0.340 nm have been refined successfully indicating a reduced occupation of octahedral Fe sites.

D. Vollath, D. V. Szabo, R. D. Taylor, J. O. Willis, J. Mater. Res., Vol. 12, No. 8 (1997) 2175-2182

P05.24.007 SYNTHESES AND STRUCTURAL CHARACTERIZATIONS OF TWO NEW NANOPOROUS MANGANESE-GALLIUM PHOSPHATES. K. F. Hsu, S. L. Wang Department of Chemistry, University of Tsing Hua, Hsinchu 300, Taiwan

Hydrothermal syntheses of gallium phosphates characterized with nanoporous structures and catalytic properties have been investigated. By employing various organic cations as structure-directing reagents, piperazine and 4, 4'-trimethylenedipiperidine, two novel manganese-substituted gallium phosphates, $(C_4N_2H_{12})_2Ga_6(H_2O)Mn(PO_4)_8$ (1) and $Ga_4Mn_3(H_2O)_6(PO_4)_6$ (2), were obtained respectively. Phase 1 adopts a 3D open framework, which consists of GaO_6 octahedra, GaO_5 bipyramid and GaO_4, MnO_4 and PO_4 tetrahedra. These polyhedra are interconnected via a corner-sharing manner to give a zeolitic framework in which 8-, 6- and 4-membered straight channels are formed inside the structure. The piperazinium cations are residing in the tunnels and staggering along the direction of 8-membered channels. In search for larger channels inside the framework, we replace piperazine with 4, 4'-trimethylenedipiperidine under the same hydrothermal condition. A new 3D framework of 2 was then formed. The framework is built up of MnO_6 octahedra, GaO_5 bipyramid and PO_4 tetrahedra in which three MnO_6 octahedra and one PO4 tetrahedra are linked by the edge-sharing forming a tetrameric unit. The tetrameric units were extended into a 3D framework by the corner-sharing with GaO_5 bipyramid and PO_4 tetrahedra. The oxidation states of Mn atoms in both structures are determined to be "+2". In this paper, hydrothermal syntheses, crystal structures, and thermal properties of the title compounds will be presented in detail.

P06.24.001 NEUTRON DIFFRACTION STUDY OF THE STRUCTURAL CHANGES, INDUCED IN NICKEL FOILS BY PULSED ELECTRON BEAM IRRADIATION. V.V.Sikolenko, G.D.Bokuchava, S.A.Korenev, A.V.Kalmykov Joint Institute for Nuclear Research, Dubna, Russia

Here we present the results of the high resolution neutron diffraction study of the structure changes of nickel foils, irradiated by the high-current pulsed electron beam with different fluxes.

The experiments on foil irradiation were carried out at the ELIONA experimental setup intended to produce electron and ion beams. We used an explosive emission vacuum diode with an Arcadyev-Marx pulse voltage generator. The beam current is exceed 1000 A with a pulse duration equals to 300 ns. The neutron diffraction experiments were carried out at the high resolution Fourier diffractometer HRFD at the IBR-2 pulsed nuclear reactor. Unirradiated, and irradiated for 10 and 20 minutes nickel foils were investigated. As a result of high temperature gradient, an elastic deformation wave arises in the irradiated foil. We demonstrate linear enhancement of the lattice parameter with an increase of flux as a result of the action of the deformation shock wave. The recrystallisation from the melted condition takes place in the period between electron beam pulses. This process can be accompanied by partial amorphisation. But the analysis of the main diffraction peaks width dependence on their positions for samples irradiated by different fluxes, shows the absence of amorphisation.

P06.24.002 ON-LINE X-RAY ANALYSIS SOFTWARE OF THE TITANIUM AND IRON ALLOYS. A.R.Gokhman X-Ray Laboratory, Department of Physics, SU Pedagogical University, Staroportofrankovskaya 26, 270020-Odessa, Ukraine

Correlation formulas between X-ray Analysis data and mechanical properties of the Ti and Fe alloys are found under working out of the On-line X-ray analysis software. Young modulus, shear modulus, yield stress, strength and plasticity coefficient are considered as the mechanical characteristics.

Integral texture parameters (ITP), residual stress of the first and second kind, X-ray residual strain, X-ray elastic moduli (XEM) and average size of crystallites are determined from X-ray investigations. Elastic moduli are measured by dynamic method. Other mechanical characteristics are measured on the testing machine “INSTRON”.

Average size of crystallites and residual stress of the second kind are found from the physical broadening. X-ray residual strain is measured from the angle position of the set of X-ray lines. ITP are calculated by probabilistic method from the two experimental inverse pole figures of some directions in the titanium or iron alloys. Due to the extrapolation procedure complete pole figure (PF) (222) is found from incomplete PF and then ITP of the iron alloys are calculated by method that uses the elastic isotropy of the (222) crystallographic plane of the cubic crystals. ITP of the hexagonal titanium alloys are determined by the likely way from incomplete PF (0002).

XEM are calculated from PF(222) and (0002) in accordance with choice of the X-ray line for measuring of the residual strain. Residual stress are found from the residual strain and XEM by a Hook's law. Correlation formulas for software of the On-line X-ray Analysis are determined for Fe and Ti alloys after rolling as well as after thermal and mechanical-thermal treatment.

P06.24.003 ON-LINE X-RAY ANALYSIS SOFTWARE OF THE PBS PHOTODETECTORS. A.R.Gokhman. A.Ye. Kiv, X-Ray Laboratory, Department of Physics, SU Pedagogical University,Staroportofrankovskaya 26, 270020-Odessa, Ukraine

Polycrystalline PbS-layers are advanced materials for obtaining of high-sensitive photoresistors in the IR field. Dark resistance and noise voltage are the important characteristics of PbS resistors. The problem to predict these parameters on the base of X-ray data is the problem of our presentation.

The films photoelectical properties-average grain size extreme dependence has been found. The properties of PbS films are symmetrical with respect to the axis normal to them surface plane. It allows consideration of the crystallographic texture as axial and to describe it by inverse pole figures but not ODF. The values of texture parameters defining the films optimum characteristics are found. The most preferable texture component is the axial component <200> with percentage in 37-38% interval. The high level of PbS-resistors flicker-noise-to- so-called X-ray elastic constants correlations is revealed also. A minimum noise level and maximum value of the dark resistance of the PbS films corresponded to residual strain 0.0006 and residual strain – 7.8MPa. It is based the following conclusion: under applying of the Pbs physical layers the main problem is not to take off fully the mechanical strain and stress but to to lead theirs to the given optimum values.

On-line X-ray analysis software of the dark resistance and noise voltage of PbS photodetectors is worked out.

P07.24.001 Ni PARTICLES ON SILICA STUDIED BY ANOMALOUS SMALL ANGLE SCATTERING. F. Berg Rasmussen, A. M. Molenbroek, B. S. Clausen, Haldor Topsøe Research Laboratories, Lyngby, Denmark and R. Feidenhans'l, Condensed Matter Physics and Chemistry Dept. Risø National Laboratory, Roskilde, Denmark.

Nano-dispersed Ni particles on silica and alumina supports play an important role in catalysis. Ni is used as a catalyst for e.g. steam reforming but also as a promoter in e.g. Mo-based catalysts for hydrotreating.

This contribution concerns ASAXS investigations of Ni particles on silica performed at the JUSIFA beamline in HASYLAB, Hamburg. The extracted small angle scattering of the Ni-particles is characterised by two regimes. At low q-values the intensity is proportional to q^{-D} with $D \approx 3$ indicating scattering from compact aggregates. At high q-values $I \propto q^{-D}$ ($D \approx 4$) known as the Porod region.

From the cross-over between the two regions an estimated size of the scattering particles of 90 Å is obtained in reasonable agreement with a mean Ni particle size estimated from the broadening of x-ray powder diffraction lines. We interpret the extracted scattering curve in terms of a hard-sphere model and extract a particles size distribution of the Ni particles.

P08.24.001 CHARACTERISATION OF THE MICRO-STRUCTURES OF ISOTHERMALLY TRANSFORMED MARTENSITE AT LOW TEMPERATURE IN Fe-23Ni-3.6Mn ALLOY BY RIETVELD'S METHOD. A.Chanda, H.Pal, and M.De, Department of Materials science, Indian Association For the Cultivation of Science, Jadavpur, Calcutta-700 032, India.

The present study reports x-ray characterisation of the microstructures of the martensites of Fe-23Ni-3.6Mn alloy, transformed isothermally at low temperature, both in the austenite powder and bulk forms of the material. The analysis is done adopting Rietveld's whole X-ray profile fitting method incorporating preferred orientation of the crystallites. Martensitic transformation for annealed powders of grain size~50μm of this alloy done at 150K revealed the highest degree of transformation showing about 8 volume percentage of martensites. This value is about 81% for cold-worked powders (at R.T) and 69% for bulk transformed at 170K, each showing the highest degree of transformation. The results of the x-ray profile study also revealed the state of the microstructure of both the austenite (fcc) phase and the martensitic (bcc) phase in terms of various x-ray line profile-related defect parameters viz. stacking faults, compound fault probabilities, crystallite (domain) sizes, r.m.s. strains, dislocation density etc. On comparing the results it is found that the martensitic phase has smaller crystallite size, larger r.m.s. strain, higher dislocation density compared to those of the austenite. The value of microhardness for the bulk martensite is considerably higher compared to that of the bulk austenite.

P08.24.002 X-RAY STUDIES ON THE KINETICS OF MICROSTRUCTURAL EVOLUTION OF Ni_3Al SYNTHESIZED BY BALL-MILLED ELEMENTAL POWDERS. M.De, S.K.Shee, Department of Materials Science, Indian Association for the Culltivation of Science, Jadavpur, Calcutta-700 032, India, S.K.Pradhan, Department of Physics, University of Burdwan, West Bengal, India.

The study reports the x-ray characterization of microstructures as evoluted in course of ball-milling of elemental blends of Ni and Al mixed in the nominal composition of Ni_3Al. The kinetics of evolution of the products at various intermediate stages of milling, starting from the initial to final, have been studied through the evaluation of X-ray profile-related defect parameters viz. stacking faults, crystallite sizes, r.m.s.strains, dislocation densities, percentage of different phases formed as a function of milling time. The method of analysis used involves Rietveld's whole profile fitting technique. The results reveal formation of increased NiAl solid solution at the early stages of milling, transforming gradually to fully disordered intermetallic Ni_3Al at about 57 hrs of milling .The final milling product possessed high propensity of faulting with high r.m.s.strain and dislocation density ($\sim 10^{12} cm^{-2}$). The crystallite sizes assumed nano-order dimension.

P08.24.003 A FEW COMMENTS ON PSEUDOVOIGT PROFILES. Prabal Dasgupta, Department of C.S.S., Indian Association for the Cultivation of Science, Jadavpur, Calcutta 700 032, India.

The analytical expression of pseudovoigt function used by most of the crystallographers is written as

$$I_p(x) = I_p[\eta\, C(x) + (1-\eta)\, G(x)]$$

Where $C(x) = (1+x^2)^{-1}$ and $G(x) = \exp[-(\ln 2)x^2]$ with $x = (2\theta - 2\theta_0)/ w$; $w = ½$ FWHM and η = Cauchy content, $2\theta_0$ is the position of the peak maxima. This work reveals that for above form of Pseudovoigt function Cauchy content η must be greater

than 0.328, otherwise no meaningful result in terms of crystallite size can be extracted from it. η values published by three authors viz Benedetti et al (1988) J. Appl. Cryst. 21 543-549, Sanchez-Bajo et al (1997) J. Appl. Cryst. 30 427-436 and Le Bail et al (1997) J. Appl. Cryst 30 265-271, agree with the present theory.

An expression for $\langle D \rangle_v$ / $\langle D \rangle_a$ in terms of η alone has also been worked out. Efficacy of this expression has been tested with η and $\langle D \rangle_v$ and $\langle D \rangle_a$ values published by Bendetti et al (1988) J. Appl. Cryst 21 543-549.

P08.24.004 MICROSTRUCTURE AND GROWTH KINETICS OF NANOSCALE CRYSTALLITES OBTAINED FROM HYDRATED CERIUM OXIDES. D. Louër, N. Audebrand and J.-P. Auffrédic, Laboratoire de Chimie du Solide et Inorganique Moléculaire, Université de Rennes I, 35042 Rennes, France.

Previous X-ray diffraction line broadening studies of nanoscale CeO_2, prepared from the thermal decomposition of mixed cerium nitrates, have revealed spherical crystallite shapes and the presence of microstrains [1]. In the present study, two hydrated oxides, $CeO_2.xH_2O$, have been obtained from hydrolysis by ammonia of $Ce(SO_4)_2.4H_2O$ and $(NH_4)_2Ce(NO_3)_6$ solutions. Due to a severe diffraction line broadening, the microstructure has been characterised by pattern modelling, using a trial-and-error procedure based on the Rietveld method. In the case of the ex-sulphate phase, crystallites are isotropic with a diameter of 19 Å. The nanoscale cerium oxides, named *sul*-CeO_2 and *am*-CeO_2, have been prepared by dehydration of the hydrated phases, in both isothermal and dynamical régimes. Powder diffraction data have been collected with a high-resolution diffractometer (isothermal mode) and with temperature-dependent X-ray diffractometry (dynamical mode). Crystallite size and shape have been determined from sixteen diffraction lines with the Fourier analysis (software *Prof*FOU [2] based on the output data from *PROFILE*/Socabim) and, also, with the Langford method for samples prepared isothermally, while a simplified procedure was applied to the resolved diffraction line 111 in the dynamical diffraction study. It has been shown that the crystallites are, on average, spherical and that *am*-CeO_2 contains a small amount of microstrains decreasing with temperature, whereas *sul*-CeO_2 is strain-free whatever the preparation temperature. Crystallite growth has been studied in the temperature range ~300-800 °C showing an increase of the diameters D from ~50 Å to ~1000 Å. The crystallite growth kinetics follow the general law $D = Kt^n$. It is shown that strain-free CeO_2 with controlled crystallite size and shape can be easily prepared and that *sul*-CeO_2 appears as a candidate for a reference material in terms of crystallite sizes.

P08.24.005 ON THE RELIABILITY AND APPLICABILITY OF PROFILE FITTING METHOD: A CASE STUDY. S. P. Sen Gupta, Partha Chatterjee, Department of Materials Science, IACS, Jadavpur, Calcutta-700032, India

A critical analysis of the Powder Profile Fitting method in connection with line broadening studies on Warren-Averbach method of Fourier analysis is presented. It is observed that for narrow and asymmetric profiles the correspondence of the Fourier coefficients is good only in the small n or column length region. For broad and symmetric profiles the Profile fitting method yields good results. Moreover, the hook effect is minimized indicating that a good powder profile analysis based on single reflection is possible. This is illustrated with recent experimental data.

P08.24.006 IN-SITU HIGH TEMPERATURE X-RAY ANALYSIS OF MgO-CaO-RICH BASIC REFRACTORIES UP TO 1600°C IN AIR. A. Preisinger and L. Petrás, Institute of Mineralogy, Crystallography and Structural Chemistry, Techn. University of Vienna, Getreidemarkt 9,A-1060 Vienna, Austria and M. Fuehrer, Institute of Mineral Processing and Refractories, University of Leoben, Leoben, Austria and K. Riepl, Veitsch-Radex AG, Research Institute Leoben, Leoben, Austria.

Basic refractory samples in the compositional range of 60-80%wt. MgO, 15-30%wt. CaO and <5%wt. Fe_2O_3, <1%wt. SiO_2 and <1%wt. Al_2O_3 as well as samples in the range of 50-60%wt. CaO, 20-30%wt. MgO, ~15%wt. Fe_2O_3, 7%wt. SiO_2 and 0,3%wt. Al_2O_3, respectively have been investigated in a high temperature PMP 1600 type [1] powder diffraction chamber in combination with Philips X´Pert MPD in Θ-Θ geometry using Cu-Kα radiation. The starting samples have been chemically analysed by means of XFA. Quantitative phase compositions have been determined using RIETVELD refinement at room temperature and "in situ" in the temperature range between 800°C and 1600°C.

In the low SiO_2 containing samples between 900°C and 1000°C Periclase, Lime and Brownmillerite have been found. At higher temperatures of 1300°C to 1400°C a partial melting process occurs which causes Brownmillerite lines to vanish. The high SiO_2 containing samples showed additionally reaction between Dicalciumsilicate and Lime giving Tricalciumsilicate at about 1300°C. Comparison of the RIETVELD refinement derived thermal expansion values with literature data [2] allows the determination of trace element content in MgO and CaO at different temperatures. Phase transitions and reactions are given in detail.

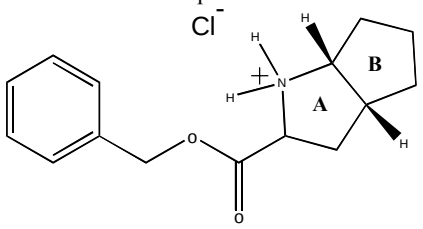
P08.24.008 ABSOLUTE CONFIGURATION OF RAMIPRIL INTERMEDIATE. K. Vyas, J. Moses Babu, S. Raju, P. Rajender Kumar, M. R. Sarma, G. Om Reddy, Dr. Reddy's Research Foundation, Bollaram Road, Miyapur, Hyderabad - 500 050.

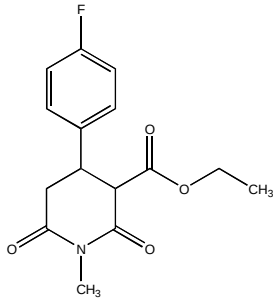
The title compound, [S,S,S] azobicyclo [3,3,0] octane-3-carboxylic acid benzyl ester hydrochloride, is an important intermediate in the synthesis of the anti-hypertensive drug, Ramipril. The compound is crystallized from n-propanol and methanol mixture. It crystallizes in the orthorhombic space group $P2_12_12_1$ with a = 9.869(1), b = 19.483(3), c = 7.451(1) Å, V = 1432.7(3) Å^3, Z=4. The intensity data were collected on a Rigaku AFC7S diffractometer with Cu Kα radiation. The structure is solved by direct methods (SIR92) and refined by least square methods. The present R factor is 4.4%. It is interesting to note that the ring junction between A & B is "cis" and two rings are like an open book. These two rings subtend an angle of 59°. There is hydrogen bonding interaction between chloride ion and nitrogen. Absolute configuration of the molecule has been determined to be SSS by means of anomalous dispersion measurements.



* DRF Publication No.: 90

P08.24.009 CRYSTAL STRUCTURE OF PEROXETINE INTERMEDIATE. A. Sivalakshmidevi, K. Vyas, P. Rajender Kumar, T. Suresh, M. R. Sarma and G. Om Reddy, Dr. Reddy's Research Foundation, Bollaram Road, Miyapur, Hyderabad - 500 050.

The compound 3-ethoxycarbonyl-4- (4-fluorophenyl) -1-methyl -2,6-piperidinedione is an intermediate of Peroxetine. The compound is crystallized from ethyl acetate. It crystallizes in the triclinic space group P-1 with a = 11.976(2), b = 12.232(2), c = 10.667(2) Å, α = 106.13(1), β = 94.75(1), γ = 72.16(1), V = 1428.8 (4) Å^3, Z=4. The intensity data were collected on a Rigaku AFC7S diffractometer with Cu Kα radiation. The structure is solved by direct methods (SIR92) and refined by least square methods. There are two independent molecules in the unit cell. The piperidinedione ring assumes sofa conformation as evidenced by endocyclic torsion angles. The molecules are stabilized in the lattice by vander Waals interactions. The R factor is 6.9% for 3189 observed reflections.



* DRF Publication No.: 89

P08.24.010 CRYSTAL STRUCTURE OF QUINAZOLINONE DERIVATIVE. K. Shashi Rekha, R. Vasu Dev, J. Moses Babu, K. Vyas, M. Ravikanth Reddy, C. Prabhakar, M. R. Sarma and G. Om Reddy, Dr. Reddy's Research Foundation, Bollaram Road, Miyapur, Hyderabad - 500 050.

A new quinazolinone derivative was prepared as an intermediate during our research on discovery of anti-diabetic drugs. The mass spectrum displayed a molecular ion at m/z = 280 corresponding to the molecular formula $C_{16}H_{12}O_3N_2$. Steady state 1D-nOe experiment by saturation of the methyl singlet at δ 2.12 gave dipolar contact to the ortho aromatic proton at δ 7.60, fixing the site of the phenyl group on the quinazolinone moiety. Interestingly the compound (1) exhibits polymorphism. Crystal structure of one of the polymorphs has been solved by single crystal X-ray diffraction technique.The X-ray structure provides unambiguous proof for the structure elucidated from spectral data.

The compound is crystallized from methanol. It crystallizes in the orthorhombic space group Pbca with a = 18.375(5), b = 20.094(2), c = 7.214(2) Å, V = 2663.5 (5) Å^3, Z = 8. The intensity data were collected on a Rigaku AFC7S diffractometer with Mo Kα radiation. The structure is solved by direct methods (SIR92) and refined by least square methods. The final R = 0.067, R_w = 0.038 for 1529 observed reflections.

The dihedral angle between the two aromatic rings is 92°. The molecules are stabilized by inter molecular hydrogen bonding between hydroxyl group and the nitrogen (N1) of quinazolinone.

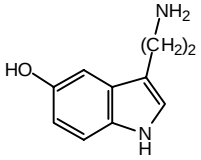
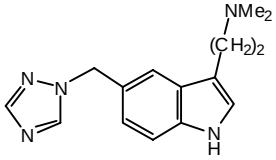
P08.24.011 CRYSTAL STRUCTURES OF RIZATRIPTAN BENZOATE AND SOME ANALOGUES. Nancy N. Tsou and Richard G. Ball, Merck Research Laboratories, P.O. Box 2000, Rahway, New Jersey, 07065-0900, USA.

A large amount of recent work[1-3] has greatly expanded our knowledge of the diversity of serotonin (5-HT) (**1**) receptors. These receptors are implicated in a broad range of neurotransmission dysfunctions and the search for receptor subtype-specific ligands for use as pharmacological tools and therapies has lead to some interesting results.



1



2

The 5-HT$_1$ family of receptors appears to comprise at least five subtypes and agonist ligands specific to the 5-HT$_{1D}$ receptor appear to be effective in the treatment of migraine. To date, agonists with high specificity for the 5-HT$_{1D}$ receptor are all based[4] on a 3,5-disubstituted indole framework in which the 3 substituent is a short alkyl chain carrying an aminic nitrogen and the 5 substituent (OH in serotonin itself) can range through a variety of hydrogen-bond acceptor groups. Since the structural literature contains no examples of this class of compounds we are reporting herein the structures of Rizatriptan (**2**) and three related indoles. They are discussed in terms of their biological activity as well as their solid-state conformations.

P08.24.012 CONFORMATIONAL FEATURES OF SOME DIAZAPINE MOLECULES. M. Suresh Kumar, D.Kumaran, and M.N.Ponnuswamy, Department of Crystallography and Biophysics, University of Madras, Guindy Campus, Chennai – 600 025, India and K.Chinnakali and H.K.Fun, School of Physics, Universiti Sains Malaysia, Penang, Malaysia.

Many derivatives of the benzodiazapine family display pharmacological properties such as tranquilizing, muscle relaxant, anticonvulsant and sedative effects. Benzodiazapines are in general not depressants of the CNS but they affect only discrete areas of the brain. The crystallographic studies of some diazapine derivatives have been done to understand the Structure Activity Relationships (SAR).

The structures were solved by direct methods and refined by full-matrix least-squares procedures. The diazapine ring in all the molecules adopt distorted boat conformation. The structures are stabilized by C-H...O and C-H...N type of interactions in addition to van der Waals forces. A comparative study on these compounds reveals many interesting results and will be presented.

P08.24.013 CONFORMATIONAL ASPECTS OF SOME PIPERIDIN-4-ONES. M.N.Ponnuswamy, M.Suresh Kumar and D.Kumaran, Department of Crystallography and Biophysics, University of Madras, Guindy Campus, Chennai – 600 025, India.

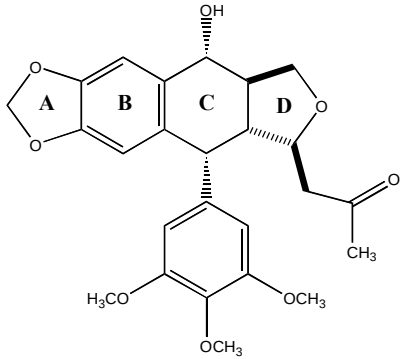
The piperidine derivatives are found to be pharmacologically important but their N-nitroso derivatives are found to be carcinogens in nature. Though the unsubstituted N-nitrosopiperidines are potential carcinogens, the alkyl/aryl derivatives are found to be non-carcinogens. It appears that blocking of the (-positions to the ring nitrogen atom by methyl groups in cyclic nitrosamines is responsible for reducing the carcinogenic acitiviy. Bulkiness of the substituents at different positions of piperidine ring reduces the carcinogenicity. To correlate the structure with activity, a series of piperidinone derivatives have been studied by crystallographic methods. In N-alkyl and N-free piperidine derivatives, the piperidine ring adopts chair conformation but in N-electron withdrawing piperidine derivatives, it adopts boat conformation. The detailed conformational aspects including the energy concepts are to be presented.

P08.24.014 STRUCTURE AND CONFORMATION OF SOME AZA BICYCLIC RING COMPOUNDS. D.Kumaran, and M.N.Ponnuswamy, Department of Crystallography and Biophysics, University of Madras, Guindy Campus, Chennai –600 025, India.

Several 3-azabicyclononanes have been synthesized and studied widely in view of their conformational flexibilities and intermolecular interactions. These compounds also possess medicinal and pharmacological properties. The substituent effects on the conformation of the bicyclic ring systems are analysed and presented. The crystallographic studies on 2,4-diaryl azabicyclononanes show that the bicyclic ring sytems adopt chair-chair conformation. When electron withdrawing groups such as acetyl, nitroso and ester groups are substituted at the nitrogen atom, the piperidine ring gets distorted. The detailed conformational analysis on the diazabicyclo [5.3.0] decanone derivatives indicate that the bicyclic ring system adopts chair-envelope conformation with slight distortion. The conformational restriction is imposed due to the presence of two torsional constraints in the seven membered ring, namely, the planar rigid lactam group (N-C-O) and the fusion to a five membered ring. The energy calculations have also been carried out and presented.

P08.24.015 CRYSTAL STRUCTURE OF 9-DEOXO-9-[2"-OXOPROPYL] PODOPHYLLOTOXIN. Y. Ravindra Kumar, A. Sivalakshmidevi, K. Vyas, G. Om Reddy, B. Renuka and D. Subrahmanyam, Dr. Reddy's Research Foundation, Bollaram Road, Miyapur, Hyderabad - 500 050.

The title compound is semi-synthetic derivative of Podophyllotoxin with in vitro cytotoxic activity. The compound is crystallized from methanol and dichloromethane mixture. It crystallizes in the orthorhombic space group $P2_12_12_1$, with a = 13.221(10), b = 28.806(9), c = 12.526(9) Å, V = 4766.8 (4.2) Å ^{3}, Z=8. The intensity data were collected on a Rigaku AFC7S diffractometer with Mo Kα radiation. The structure is solved by direct methods (SIR92) and refined by least square methods. The present R factor is 7.1%.



There are two independent molecules in the unit cell. In both the molecules the confirmation of the rings A and D is envelope whereas the rings C assume half chair confirmation. There is an intermolecular hydrogen bonding between the hydroxyl oxygen atoms of the independent molecules.

P08.24.016 STRUCTURES OF A HYDROXAMIC ACID INHIBITOR COMPLEXED WITH MMP1, MMP3, AND MMP13 F. Gu, C.M. Dunaway, L. Chen, T. Rydel, M.G. Natchus, G.E. Mieling, B.L. Barnett Structural Biology, Discovery Research, Procter & Gamble Pharmaceuticals, Mason Ohio, 45040, USA

MMP inhibitors are potential therapeutic agents for various diseases including cancer and osteoarthritis. Recent data from clinical trials with MMP inhibitors indicate that there is a great need for selective inhibitors. X-ray crystallography has been used as a tool to help understand specific binding interactions of inhibitors to various MMPs. We report in this study several structures of a hydroxamic acid inhibitor complexed to MMP1, MMP3, and MMP13 catalytic domains. The inhibitor was soaked into the MMP3 crystals or co-crystallized with the enzyme. Large conformational changes at the active site have been noted when comparing the structures of the active MMP3 catalytic domain and the one inhibited. The same inhibitor has also been co-crystallized with MMP1 and MMP13. Comparisons of the structures of three inhibited enzymes, MMP1, 3, and 13 show that MMP3 and 13 are extremely similar. There are major differences in the binding pockets, especially in the S1' pocket between MMP1 and MMP3/13. These studies can help design more selective inhibitors.

P09.24.001 HYDROTHERMAL SYNTHESIS & CHARACTERIZATION OF U-POROUS ZINC-GALLIUM PHOSPHATE $[N_2C_6H_{16}][Ga_2Zn_2P_4O_{16}]$. Chia-Heir Lin [1], Sue-Lein Wang [2]. [1] Department of Chemistry, National Tsing Hua University, Hsinchu, Taiwan 300. [2] Department of Chemistry, National Tsing Hua University, Hsinchu, Taiwan 300

A novel compound of $[N_2C_6H_{16}][Ga_2Zn_2P_4O_{16}]$ (1) has been prepared under mild hydrothermal conditions and structurally characterized by single-crystal X-ray diffraction and thermal analysis. Crystal data for compound 1 is as follows: a = 14.3196(7) Å, b = 16.2550(8) Å, c = 8.8552(4) Å, β = 90.134(1)°, V = 2061.18(4) Å^3, Z = 4, R = 0.0407 for 3703 observed reflections with I>3σ(I). Compound 1 adopts a 3D open framework structure which contains three types of tetrahedra: GaO_4, ZnO_4, and PO_4. These tetrahedra are interconnected via a corner-sharing manner to give a zeolitic framework in which large channels are formed. The protonated 1,2-diaminocyclohexane cations are residing in the tunnels. The hydrothermal synthesis, crystal structure, and thermal properties of the title compound will present in detail.

25. CRYSTALLOGRAPHIC TEACHING

P12.25.001 TRAINING IN RESEARCH INSTITUTIONS AS AN EFFECTIVE TOOL OF TEACHING CRYSTAL GROWTH FOR CRYSTALLOGRAPHERS. N.I.Leonyuk, Dept. of Crystallography and Crystallochemistry, Geological Faculty, Moscow State University, Moscow 119899, Russia; V.I.Lyutin, E.V.Polianski, P.P.Chvanski, A.A.Mar'in, S.A.Smirnova, S.Yu.Stepanov and N.G.Sanzharlinski, VNIISIMS, Aleksandrov 601600, Vladimir Distr., Russia

Crystal growth is being taught in many universities, and the course scope specifically depends on the profile of interests of the department and/or college. Our crystal growth course has evolved as a self-consistent curriculum for students-crystallographers of Moscow State University (MSU) in collaboration with other universities, academic institutions and industry. There are three stages of this long-term crystal growth teaching: (1) general course of lectures and seminars for all students; (2) training and laboratory courses for all students; (3) research work for students-crystal grower. This paper concerns of the research training of the MSU students in laboratories of the All-Russian Research Institute for the Synthesis of Minerals (VNIISIMS) for nearly three decades. This four-week training is offered for students after the 3rd academic year and covered topics: (a) Hydrothermal growth of piezo-quartz; (b) Hydrothermal growth of optical calcite; (c) Hydrothermal growth of zincite; (d) Czochralski growth of bismuth orthogermanate crystals; (e) Growth of rare earth aluminate crystals by zone melting; (f) Synthesis of diamond. At the end of this training, all the students should complete and defend publicly their research projects. The research training provides a helpful practical experience, many important details for the course and can help with making some models of crystal growth more concrete. It also allows students to take knowledge and practical experience concerned with obtaining crystalline materials required for their own experimental programs. Strong interaction and integration between the University Education Program, Research Institutions, and Industry seems to be one of the keys to developing effective researchers and engineers for the future.

P12.25.002 SOFTWARE FOR CALCULATING DIRICHLET DOMAINS. N.E.Kashcheeva and D.Y. Naumov, Novosibirsk State University and Institute of Solid State Chemistry and Mechanochemistry SB RAS, Kutateladze, 18, Novosibirsk, 128, 630128 Russia.

A computing program NADI for calculating and visualizing the Dirichlet domains in crystal structures is described [1,2]. NADI allows one to calculate DD choosing optionally the types of atoms to be considered, the atomic / ionic radii, and the method of dividing the distances between the atoms by planes. This flexibility makes it possible to choose between the application of various published methods and, if necessary, to compare the results they give for the same system. The program can operate both with points (of one or several types) and with spheres (of the same or of different radii). It is possible to operate also with centroids of molecules or molecular fragments, or with any other selected points.

NADI calculates the volumes of DD, the number and the areas of faces, the solid angles corresponding to the faces, the distances from the central atom to the atoms that give rise to the faces, the distance to the nearest face and to the furthest vertex of DD. Symmetry codes and the coordinates of points in the structure corresponding to the faces of DD are also given. The calculated data are prepared as an output file, and can be also (optionally) viewed on the screen in various projections and rotated quickly or slowly. The DD can be shown with respect to crystallographic axes of the structure and also with respect to the atoms of the crystal structure (either all or selected). NADI can generate plots in HPGL format.

2. N. E. Kashcheeva, D. Yu. Naumov, E. V. Boldyreva, accepted to Z.Krist.

P12.25.003 TITAN: A PROGRAM TO AID STRUCTURE SOLUTION AND REFINEMENT WITH THE SHELX SUITE OF PROGRAMS. Jim Simpson and Keith A. Hunter, Department of Chemistry, University of Otago, P.O. Box 56, Dunedin, NEW ZEALAND.

TITAN is a Windows based molecular graphics program designed to be used exclusively in conjunction with the SHELX-97[1] suite of programs. The program facilitates the on-screen assignment of peaks from the direct methods E-map or Patterson map, generated by SHELXS-97, to individual atom designations. Once these designations are completed, a file is written that can be input directly to the SHELXL-97 refinement program without modification. *TITAN* can also be used in the location of additional atoms in series of least-squares and difference Fourier cycles and as an aid to the inclusion of hydrogen atoms into the refinement using the HFIX and/or AFIX commands.

TITAN is a 32-bit program and runs in the Windows-95/98 or Windows NT environment It also serves as a shell from which to launch the SHELXL refinement program so that the complete refinement of a structure can be completed within the program. Hard-copy plots can be obtained using any Windows compatible printer. A demonstration of the operation of the *TITAN* program will be given as part of this poster presentation.

27. OTHER TOPICS

P07.27.001 NEW DEVELOPMENTS IN HARD X-RAY HOLOGRAPHY. G. Faigel, M. Tegze, Research Institute for Solid State Physics and Optics, H-1525 Budapest, POB 49, Hungary, S. Marchesini, M. Belakhovsky, Service de Physique des Matériaux et Microstructures, Département de Recherche Fondamentale sur la Matière Condensée, CEA Grenoble, 17 rue des Martyrs, F-38054 Grenoble, France

In the last few years a new technique, the hard x-ray holography is emerging for the study of 3D atomic arrangements in solids [1,2]. Two types of this method have been developed: one in which the atoms of the sample serve as inside sources of x-radiation, this is called "normal holography", and the other "" in which the atoms are used as detectors of the interference field originating from the incident and scattered waves this is called " inverse holography". Though the first steps in this field looked very promising, only very few experiments have been done so far. The cause of this is manifold : there are experimental and evaluation related problems. In the experimental side one of the most important point to solve is the acquisition of reliable and evaluable data at synchrotron sources. In the evaluation side a reconstruction algorithm has to be developed which gives isotropic real space resolution and suppresses the twin images and spurious oscillations. In this poster we discuss these problems and show the solutions for many of them. The results are demonstrated by experimental examples.

2. T. Gog et al. Phys. Rev. Lett. 76, 3132, (1996)

P05.00.000 DON'T TRY THIS AT HOME: HANDLING ABSTRACT SUBMISSION FOR IUCR 1999. C.C. Wilson, K. Shankland and T. Csoka, Rutherford Appleton Laboratory, Chilton, Didcot, Oxon. OX11 0QX, U.K.

The abstract submission procedure for IUCr 1999 was intended to be 100% electronic. This has been realised, indicating that we have truly entered a paperless age for crystallography conference abstract submission.

A key step in the process has been the use of a database system (based upon mySQL) which stores all information as it is received and allocates abstract numbers automatically. This, coupled with a WWW interface to the database has allowed abstracts to be received efficiently and corrections made with relatively little effort on the part of the Abstracts Team. On the other hand, e-mailed submissions have required a significantly higher level of manual intervention, as one has no control over the format of the incoming messages.

The hardware and software implementation of the abstracts server will be presented, together with the pros and cons of attempting to do everything not only electronically, but automatically.

OPEN COMMISSION MEETINGS

TB INTERNATIONAL TABLES

C06.TB.001 STATUS OF VOLUME A: SPACE-GROUP SYMMETRY. Theo Hahn, Institut für Kristallographie, RWTH Aachen, D-52056 Aachen, Germany.

The Fourth, revised edition of Volume A of *International Tables of Crystallography* appeared in 1995. Due to great demand two corrected reprints became necessary; they were published in 1996 and 1998. Presently, the Fifth, revised edition is in preparation; the scheduled publication date is spring 2000.

The Fifth edition will contain corrections of all errors and flaws known so far. The new glide-plane symbol '*e*', introduced in the Fourth edition, will be systematically incorporated in all tables, diagrams and text sections. A new Section 9.4, *Some further properties of lattices*, will be contributed by B. Gruber, Prague.

From the Fifth edition onwards, Vol. A, large parts of which were originally type-set 'by hand', will be printed from a computer-based file as follows:

the space-group tables (Sections 6 and 7) will be transferred to Latex files by Mois Aroyo and his colleagues in Sofia, Bulgaria. These files will be the basis for the printing;

the text sections will be re-keyed in Chester and printed from SGML files.

The space-group program was completed at the end of 1998; the re-keying and proofreading of the text will be done in the summer and fall of 1999. For the future, an electronic version of Vol. A is contemplated.

The Fourth, revised and enlarged edition of the *Brief Teaching Edition of Volume A* was published in 1996.

C06.TB.002 STATUS OF VOLUME B: RECIPROCAL SPACE. Uri Shmueli School of Chemistry, Tel Aviv University, 69 978 Tel Aviv, Israel.

The first edition of Volume B was published in 1993, its first corrected reprint appeared in 1996 and the work on the second edition was in an advanced stage during the 1996 IUCr Congress in Seattle.The editorial work on the second edition, now completed, consisted of (i) major revisions and/or corrections of several chapters and sections of Volume B, and (ii) incorpora- tion of the following new contributions in the second edition of the Volume:

B.1.5. Crystallographic viewpoints in the classification of space-group representations (by M.I. Aroyo and H. Wondratschek)

B.2.5.6. Direct methods in electron crystallography (by D.L. Dorset)

B.4.5. Polymer crystallography (by D.L. Dorset and R.P. Millane)

B.4.6. Reciprocal-space images of aperiodic crystals (by W. Steurer and T. Haibach)

B.5.3. Dynamical theory of neutron diffraction (by M. Schlenker and J.-P. Guigay)

An annotated Table of Contents of the second edition of Volume B will be presented and discussed in the Open Meeting. This edition of Volume B is expected to be published in the spring of 2000.

The somewhat late expected date of publication is due to the translation of Volume B to SGML (Standardized Generalized Markup Language) and the production of an electronic version of the Volume. However, this will result in great time savings in the production of future editions.

C06.TB.003 STATUS OF VOLUME C: MATHEMATICAL, PHYSICAL, AND CHEMICAL TABLES. E. Prince, NIST Center for Neutron Research, National Institute of Standards and Technology, 100 Bureau Drive, Stop 8562, Gaithersburg, Maryland 20899-8562, USA.

A revised and expanded edition of Volume C was published in the spring of 1999. Its ten parts contain 228 sections in 56 chapters, all of them written by acknowledged experts in their specialties. Two chapters, one on neutron topography and one on neutron reflectometry, are completely new. The first edition, because of a need to publish without further delay when chapters on some desired topics were still outstanding, contained several chapters that were carried over with minor editorial changes from the earlier series of *International Tables*. Of these only one remains, and that one, a chapter on the determination of refractive indices, was judged to be still sufficiently authoritative that no revision was necessary.

When work began on the first edition in 1983 and 1984, computer-based word processing systems were just beginning to appear, and authors were invited to submit machine-readable files in addition to their manuscripts. Many of them did, in a wide variety of formats, but efforts to utilize these files in the production process were almost totally unsuccessful. At the time of A. J. C. Wilson's death in 1995 the process of collecting material for the second edition was well along, but production had not yet begun. Most new text was then available on diskette, and this was successfully imported into the software used by commercial typesetters, but chapters that had received only minor revision had to be typeset again by hand. The entire text of Volume C now exists on machine-readable files, and future revisions will be much easier and cheaper.

The timely publication of this volume was made possible by the cooperation of many authors and the expert and diligent efforts of the staff in Chester. The entire crystallographic community is in their debt.

C06.TB.004 VOLUME D, PHYSICAL PROPERTIES OF CRYSTALS. Andre Authier, LMCP, Universite P.et M. Curie, Case115, 4, Place Jussieu, 75252 Paris CEDEX 05, France.

Volume D will consist of three parts: (i) Tensorial Aspects of Physical Properties, (ii) Symmetry Aspects of Excitations, (iii) Symmetry Aspects of Structural Phase Transitions, Twinning and Domain Structures. It will be accompanied by a Compact Disk with two softwares**:**

The first one, dealing with tensors and irreducible representations, calculates representations of finite 3-dimensional point groups and the components of invariant tensors in arbitrary dimension, of arbitrary rank and with arbitrary permutation symmetry of the indices under the action of a 3-dimensional crystallographic point group.

The second one, dealing with phase transitions will give tables for equitranslational phase transitions, and for tensor properties at any group-subgroup phase transition: spontaneous tensor components, up the rank 4, that appear in the distorted phase and non-zero tensor components that are the same in both phases.

It is expected that all manuscripts will have been received by the time of the XVIIIth IUCr Congress and that the volume can be printed in the 2000.

C06.TB.005 STATUS OF VOLUME E: SUBPERIODIC GROUPS - A PROGRESS REPORT. V. Kopsky and D.B. Litvin.

Abstract not available.

C06.TB.006 STATUS OF VOLUME F: MACROMOLECULAR CRYSTALLOGRAPHY - A PROGRESS REPORT. M.G. Rossman and E.A. Arnold

Abstract not available.

C06.TB.007 STATUS OF VOLUME G: CRYSTALLOGRAPHIC INFORMATION. S. R. Hall, Crystallography Centre, University of Western Australia, Nedlands 6907, Australia, and B. McMahon, International Union of Crystallography, 5 Abbey Square, Chester CH1 2HU, England.

Volume G will contain a complete specification of the crystallographic information exchange mechanism sponsored and supported by the IUCr. It is intended as a working handbook for structural crystallographers needing to exchange or archive crystallographic data and will provide up-to-date information on data definitions and CIF compliant applications. An accompanying CD-ROM will contain the dictionaries in machine-readable form and a collection of libraries and utility programs.

The volume will include the latest versions of all CIF dictionaries approved by the IUCr Committee for the Maintenance of the CIF Standard (COMCIFS), and in particular version 2.1 of the CIF Core Dictionary (originally published in *Acta Cryst.* (1991), A**47**, 655-685), together with new dictionaries for use in powder and macromolecular structure determination work.

Full documentation on the file structure of CIF and STAR Files will be provided, as well as detailed commentary on the way that the CIF data definitions are specified, and on the use of the file in data archival and publishing. Documentation of software libraries will be included for the use of software developers.

C06.TB.008 PROPOSAL, INTERN. TABLES VOL. A2: RELATIONS BETWEEN WYCKOFF POSITIONS IN GROUP-SUBGROUP RELATIONS Ulrich Müller, Fachbereich Biologie/Chemie, Universität Gh Kassel, D-34109 Kassel, Germany

The importance of crystallographic group-subgroup relations in crystal chemistry, crystal physics, and mathematical crystallography has become widely accepted. Important applications such as the derivation of structural relationships between crystal structures or the consideration of structural changes taking place during phase transitions require the knowledge of the relations among the atomic positions (Wyckoff positions) in a space group and in its subgroups. These relations have been compiled completely and will be a valuable tool for the practical work of crystal chemists and physicists.

The new tables, suggested to become volume A2 of the *International Tables for Crystallography*, contain:

1. An introductory text pointing out some applications, treating topics referred to the relations, citing the group-theoretical background, and giving instructions.

2. For every space group, a complete listing of its maximal subgroups, including the infinity of all isomorphic subgroups.

3. If needed, formulae for the transformations of the base vectors, site coordinates, and origin shifts.

4. For all Wyckoff positions of the space group, the relations to the Wyckoff positions of all of its maximal subgroups.

There is a complete one-to-one correspondence with the listings of the forthcoming volume A1, albeit with very different contents. Sample pages have been presented on two conferences [1].

1. U. Müller, Z. Kristallogr. suppl. **5** (1992) 172 and suppl. **8** (1994) 203.

ID INNOVATIVE USES OF THE INORGANIC CRYSTAL STRUCTURE DATABASES

C07.ID.001 ICSD: NEW DEVELOPMENTS. H. Behrens FIZ Karlsruhe, 76012 Karlsruhe, Germany.

In the paper the new developments for the Inorganic Crystal Structure Database (ICSD) will be described. These are i) creation of a new PC software for retrieval and visualisation, ii) the establishment of a new software system for the production of the database, iii) offer of the database via WWW, and iv) systematic corrections of a number of data. These points will be illustrated and discussed in detail.

C07.ID.002 MATERIALS DATABASES FOR THE NEXT DECADE: THE PAULING'S FILE (LPF). M.Berndt and K.Brandenburg, CRYSTAL IMPACT GbR, Postfach 1251, D-53002 Bonn, Germany, K.Cenzual, Departement de Chimie Minerale, Analytique et Appliquee, University of Geneva, Switzerland, and S.Iwata, University of Tokyo, Japan, and T.Atago, JST, Tokyo, Japan, and P.Villars, MPDS, Vitznau, Switzerland.

A new materials phases database system called "Pauling's File" is introduced to demonstrate concepts and techniques for building up a new structural database. This contribution should be taken as a case study to learn how to meet the needs for the next decade.

Pauling's File is based on a relational database system consisting of: a) Structural data such as cell, space group, atomic coordinates, etc., b) measured and calculated powder diffraction patterns, c) phase diagrams (stored as vector plots), and d) over 50 different physical properties.

The value of a scientific database depends on how much it meets the criteria of completeness and accuracy. Like other databases LPF reflects the published literature. Until today about 130,000 publications have been scanned. Accuracy is ensured by using modern scanning and OCR techniques completed by a multiple-step validation process to uncover "wrong" structures.

A comprehensive database like LPF needs flexible software tools to extract the informations. Beside a foolproof visual retrieval system and a flexible statistics program Pauling's File also includes:

a powerful 2D and 3D visualization system for crystal structures and diffraction diagrams, based on the well known DIAMOND technology. This tool can also identify structures from measured powder patterns using modelling techniques, Rietveld refinement, and search match techniques.

an innovative, semi-empiric tool to correlate atomic property expressions of its constituent chemical elements and its compound/system properties. This software was designed to discover systematically hidden patterns and should help to predict (and design) compound properties.

Further software developments are intended and proposals for collaborations are always welcome. Some examples and illustrations will be shown for the techniques and components mentioned above.

C07.ID.003 ICSD-FOR-WWW, A DEMONSTRATION OF THE LATEST FEATURES, INCLUDING BOND VALENCE. Alan Hewat, Institut Laue-Langevin, BP 156X, Grenoble 38042, FRANCE.

A demonstration of ICSD-for-WWW will show how easy it is to access the almost 50,000 structures in the Inorganic Crystal Structure Database via the WWW, or at least a local server (eg see http://barns.ill.fr/dif/icsd/). The latest features include automatic calculation of bond-valence sums as a check on the structure during preparations for visualisation using VRML.

The WWW interface looks the same on any computer, Windows-PC, Macintosh or Unix workstation. A selection of structures is obtained by entering the usual search criteria, then the search can be narrowed with additional criteria. The resulting entries can be printed out in standard reference format for cut-and-paste into manuscripts, or in EndNote bibliographic format. They can be ordered according to date, formula, author, space group or mineral name for further processing.

Individual entries can be compared, listed in full, and used to generate X-ray or neutron powder diffraction patterns, with peaks automatically indexed. Finally the 3D structure can be drawn, zoomed and rotated, with the usual space-filling, ball-and-stick or co-ordination polyhedrae models available.

The latest features include automatic calculation of Brown-Shannon valence sums to check the chemical validity of the structure, the illustration of sites of different valence state with different colours, the drawing of mixed-atom polyhedrae such as in oxy-chlorides etc.

ICSD-for-WWW servers have already been set up in France, Germany, the UK, USA and Japan, the software is distributed free of charge for a limited demonstration data-set, and also with the licence for the full ICSD data-set from FIZ Karlsruhe.

C07.ID.004 THE ICSD AS A SOURCE OF NOVEL MATERIALS. S. C. Abrahams, Physics Department, Southern Oregon University, Ashland, OR 97520, USA.

Determination of relationships between given crystal structures and their intrinsic properties, if applicable also to a wide range of structures, offers the possibility of major advances. The principal crystallographic databases provide well-organised access to published structural studies and hence allow opportunities for predicting desirable properties in series of materials that previously may have been studied for totally unconnected reasons. Systematic analysis of atomic co-ordinates in the ICSD has identified numerous materials with novel properties by virtue of relationships that depend upon the magnitudes of atomic displacement between the listed polar structure, at a given temperature and pressure, and derivative structures either in a supergroup of that listed or with a discontinuity in characteristic tensor property. Magnitudes that satisfy related structural criteria are predicted to be ferroelectric, the property that follows from this relationship. A resulting series of newly-predicted ferroelectrics has now been experimentally verified, including $Ba_6CoNb_9O_{30}$, Sr_2SbMnO_6, fresnoite, $K_2(NbO)_2Si_4O_{12}$, $YInO_3$ and $CN_4H_8ZrF_6$ among others. Analysis of all entries in five higher-symmetry polar point groups listed in ICSD has resulted in over 200 such predictions. Since many are to families with multiple members, this analysis is enough to double the present number of known single-phase ferroelectrics if all predictions prove to be verifiable. In a field of technological importance, these results demonstrate the database to be a highly effective source of materials with novel properties. Several improvements in the CD-ROM DOS version that would substantially enhance its efficacy may, however, be identified. These include upgrading it to a Windows environment and providing greater search flexibility, as available already in the WWW version. Others to be discussed include updating the nomenclature, listing all references within ICSD to a given material in each entry, improving the present structure visualisation program and providing direct access to such other visualisation programs as xtal-3d and DRAWxtl in the Virtual Reality Modelling Language format.

C07.ID.005 FROM ICSD TO SICS: A TOOL FOR ANALYZING STRUCTURAL RELATIONSHIPS. G. Bergerhoff, M.Berndt and K.Brandenburg, Institute for Inorganic Chemistry, University of Bonn, Germany.

Structural relationships between inorganic structures can be detected automatically by a fingertip in a database if

a) data are presented in an appropriate manner,

b) the interesting relationships are well defined so that they can be transformed to a program.

To fulfill the first condition data stored in ICSD from the literature have been standardized following Gelato and Parthé (J.Appl.Cryst. 20 (1987) 139-143), reduced to the ´best´ representative of each phase, and provided with the difference **Δ** between each pair of structures within an isopointal set. The details of the so-formed new database SICS (**S**tandardized **I**norganic **C**rystal **S**tructures) are described in Bergerhoff et al., Acta Cryst. B55 (1999) Issue 4.

Relationships between inorganic structures can be described in different terms: Isopointal structures, Isotypism, Antitypes, Interstitial types, Group-subgroup relations, etc. Because of the large amount of structures the full information on relationships hided in SICS can only be found by means of the new database SICS itself. It is available from the authors for subscribers of the ICSD. Here we want to demonstrate the effectivity with new examples showing the relationships between structures with octahedral coordination of one cation and of the general formula types **ABX6** (A2X6), **AB2X6** (ABCX6, A3X6=AX2), **AB3X6** (ABCDX6, ABC2X6, A4X6=A2X3), **AB4X6** (ABCS2X6, ABC3X6, AB2C2X6, A5X6), **AB5X6** (AB2C3X6, ABC4X6, ABC2D2X6, A6X6=AX), **AB6X6** (AB2C4X6), **AB7X6** (ABC6X6, AB3C4X6), **AB8X6** (AB2C6X6), **AB9X6** (AB3C6X6).

C07.ID.006 BLASTING THE *CRYSTMET* MINE: POWDER DATA, 3-D PLOTS, BEYOND THE TYPE, PROPERTIES, VIRTUAL MATERIALS. John R. Rodgers, Toth Information Systems, Inc., 2045, Quincy Avenue, Glouceter, ON, Canada, Yvon Le Page, National Research Council Canada, Ottawa, ON, Canada, Peter S. White, University of North Carolina at Chapel Hill, NC, USA, John Harris, Institut fuer Festkoerperforschung, Forschungszentrum Juelich, GmbH, D-52425 Juelich, Germany and Paul Saxe, SciCo Inc., 5031 Palermo Drive, Oceanside, CA, USA

Rapid progress in computational methods and power, combined with developments in visualization, data mining strategies and experimentation techniques (combinatorial chemistry), is creating new design opportunities in materials science. This presentation will highlight a number of developments used for mining *CRYSTMET*, currently a database of intermetallic crystal structures with corresponding calculated powder data, and integrated structure plotting software for 3-D viewing of intermetallic and inorganic structures.

Emphasis for expansion of *CRYSTMET* will be on tools for calculating structure and physical properties to complement published data. Results of first-principles density functional methods, producing accurate structural and powder information from rough structure-type data will be presented. Such quantum modelling can also be used for the calculation of electrical, optical, thermal and mechanical properties of materials in structure databases. The use of these computational methods is greatly improving the data integrity, value and usefulness of *CRYSTMET* and it is providing information which would be costly

and/or difficult to measure, especially for virtual compounds modelled after existing ones.
New concepts for the direct manipulation of *CRYSTMET*, using dynamic queries, which allow users to formulate queries with graphical widgets, such as rangesliders, toggles and alphasliders, and visualize the results as 2-D or 3-D plots will be illustrated. Such visual representation of the results of database queries is a powerful means to access information on trends, clusters, gaps and outliers, and give the user tools for data exploration.

C07.ID.007 DATA MINING USING THE ICDD POWDER DIFFRACTION FILE, RELEASE 1999: THE BENEFITS OF EXPLOITING POWDER DATA FROM THE PDF AND ICSD. J. Faber, R. Jenkins and R.L. Snyder

Abstract not available.

JR IUCr JOURNALS

C08.JR.001 OVERVIEW OF IUCR'S JOURNALS. John R Helliwell [1], Peter Strickland [2], [1] Editor-in-Chief of Acta Crystallographica and Chairman of the IUCr's Commission on Journals, Department of Chemistry, University of Manchester, M13 9PL, UK, [2] Managing Editor, IUCr, 5 Abbey Square, Chester, CH1 2HU, UK.

In the last triennium we highlight a number of developments for the IUCr Journals. Details of each Journal however can be found in the accompanying abstracts for this Journals' Open Commission session. Authors' choice within the IUCr Journals is broad, encompassing all aspects of crystallography and its cognate subjects across the sciences. The further expansion into the synchrotron field has been greatly facilitated by the Journal of Synchrotron Radiation, and which has now published the major proceedings from SRI'97 held in Japan and also the XAFS X Conference held in Chicago in 1998. The biological community expands apace and Acta Cryst D is now published monthly. Publication of the very popular 'Daresbury CCP4 Conference Proceedings' series commenced as a supplement to Acta Cryst D in 1998. Chemical crystallography capability has also greatly expanded and to handle this all crystal structure data for publication in Acta Cryst C, and Acta Cryst B, are now all submitted electronically via cif. The IUCr www coverage of the Journals, including the services to authors and Coeditors for manuscript tracking, is now extensive. A 50 year searchable index is now available, and which is a powerful tool for accessing the vast archive of IUCr publications. In the last triennium the 50th Anniversary of Acta Cryst and the IUCr occurred, as did the 30th Anniversary of J Appl Cryst. A special 50th Anniversary Issue of Acta Cryst was published in section A in November 1998, comprising especially commissioned articles. This special issue was distributed to all subscribers of IUCr Journals free of charge and is available for purchase at a very competitive price in book form. The upcoming triennium includes an expansion of electronic access for subscribers to the IUCr's Journals and a greater emphasis on the marketing of the Journal titles to the crystallographic community, as well as to structural science communities in biology, chemistry, materials science and physics. Highlighting via mini-reviews of IUCr Journal articles within the IUCr Newsletter, whose collaboration we gratefully acknowledge, also opens a channel to 15,000 readers and is clearly an exciting promotional strategy.

C08.JR.002 CRYSTALLOGRAPHIC PUBLISHING IN THE ELECTRONIC ERA. B. McMahon and P.R. Strickland, IUCr, 5 Abbey Square, Chester CH1 2HU, England, H. D. Flack, Lab. de Cristallographie, 24 quai Ernest-Ansermet, CH-1211 Genève 4, Switzerland, Y. Epelboin, Lab. de Mineralogie-Cristallographie, Tour 16, Univ. P. et M. Curie, 4 place Jussieu, 75252 Paris Cedex 05, France, and L. M. D. Cranswick, CCP14, Daresbury Laboratory, Warrington, WA4 4AD, England. (IUCr Committee on Electronic Publishing, Dissemination and Storage of Information.)

For the last half century, the IUCr has published the results of crystallographic research in its flagship journal *Acta Crystallographica*. As the new century beckons, the Union is involved in publishing a wide and growing range of journals, reference books, directories and educational materials. Increasingly, the medium of publication is electronic, on both magnetic or magneto-optic media, and the global Internet. In the last triennium the Union's Electronic Publishing Committee has been reconstituted as a technical working group with a remit to advise on and coordinate the Union's publication programme.

The Committee works closely with the Commission on Journals in the electronification of the journals described elsewhere in this session. It acts as the General Editorial Board for the web services maintained through the Chester server and at a number of mirror sites. Chester is a hub for the web-based information network, collecting material from the Crystallography World Wide and SinCris sites and from various Commissions, and supplying regular updates to the mirrors. The result is a rich information resource, conveying both topical information on subjects such as meetings, jobs and software releases, and more durable information such as journals contents, supplementary data and the records of the Union's activities. Other projects include: revision of the *World Database of Crystallographers* to expand its content and improve access; provision and management of discussion lists on specialised topics for the Union's Commissions and Committees; and investigations into suitable CD-ROM publications, including collaboration on the abstracts CD-ROM for this Congress.

C08.JR.003 ELECTRONIFICATION OF THE IUCr EDITORIAL OFFICE. P.R. Strickland and B. McMahon, International Union of Crystallography, 5 Abbey Square, Chester CH1 2HU, England.

The key concern of the IUCr Editorial Office, which is based in Chester, UK, is the rapid, accurate and high-quality publication of the Union's journals, *Acta Crystallographica*, *Journal of Applied Crystallography* and *Journal of Synchrotron Radiation*. "Electronification" of the Editorial Office has been under way for several years and has a number of aims; these include increasing the speed of publication, improving the efficiency of review, technical editing and printing processes, and the provision of electronic versions of the journals.

The main steps in the electronification process have been the introduction of the use of CIF for the production of *Acta Crystallographica Section C* in 1991 and the adoption, in 1997, of new production methods based on SGML (standard generalized mark-up language), the publishing industry standard for electronic publishing.

Most stages of the publication process have already, or will shortly, become electronified. Submission of electronic manuscripts will be joined by electronic review procedures and electronic proofs. Transmission of papers to our printers is already an electronic process, and electronic versions of the journals will become available shortly. Other publications produced by the Editorial Office, *e.g. International Tables for Crystallography*, will also be electronified.

These developments will be described and the experience gained from them will be discussed.

C08.JR.004 ACTA CRYSTALLOGRAPHICA, SECTION A, FOUNDATIONS OF CRYSTALLOGRAPHY. Andre Authier, LMCP, Universite P.et M. Curie, Case115, 4, Place Jussieu, 75252 Paris CEDEX 05, France.

In the triennium 1996-1998, Section A has published 18 bimonthly issues and a special issue dedicated to the 50th Anniversary of Acta Crystallographica and of the IUCr. The total number of pages was 2922, corresponding to 227 Research Papers, 3 Lead Articles, 2 Topical Reviews, 26 papers in the special issue, and 32 Short Communications. The number of pages and of papers published in 1997 was low, but picked up again in 1998. Many efforts have been devoted successfully at every stage to reduce the processing and printing time and these efforts will continue as this is a crucial issue.

The Guest Editor for the Special Issue was Professor Henk Schenk. The Special Issue starts with a paper about the history of the IUCr and spans all aspects of crystallography, symmetrical, structural, physical, chemical and biological, with papers devoted to the most important landmarks in the development of crystallography over the past 50 years. It was also reprinted as a book, under the title, "Crystallography across the sciences". This special issue is undoubtedly a success and more are planned. More Lead Articles and Topical Reviews are also in the pipeline.

The format of Section A seems well adapted to its purpose and no suggestions to modify it have been received in the past, but any suggestion for modification and improvement will be welcome.

C08.JR.005 ACTA CRYSTALLOGRAPHICA, SECTION B Frank H.Allen, CCDC, 12 Union Road, Cambridge CB2 1EZ, England.

Section B of Acta began publication with the section title "Structural Science" in 1983. From the outset its remit was to publish original research papers and short communications in which 'structure' was the central theme of each article. During the '90s, this remit has extended to the publication of limited review material as Lead Articles or Topical Reviews. Originally, Section B was concerned with the chemical, physical and biological implications of novel structure determinations, or of systematic analyses of existing structural information retrieved from databases. The loss of the biological component to the newly created Section D of Acta in 1993 led to some initial reduction in Section B submissions.

Section B now publishes papers in structural chemistry and physics across a broad spectrum from inorganics and minerals, through metal-organics to purely organic compounds. Within that spectrum, experiments at non-standard temperatures and pressures, and studies of the physical properties of novel materials, phase transitions, charge densities, intermolecular interactions, supramolecular structural organisation, database applications, and structure determination from powder data, reflect current leading-edge developments in the subject area.

In the triennium 1996-1998, Section B has published 18 bimonthly issues (3066 pages) containing 335 full papers, 16 short communications and 3 topical reviews (with more in the pipeline). On the basis of citation statistics, Section B has an impact factor of 1.612 and is ranked 4th of 17 crystallographic journals, the top three also being IUCr publications. Machine-readable submissions to Section B have become a reality during the triennium.

Comments on the future development of Section B will be welcomed. Issues for discussion might include (a) complementarity between Section B and Section C, (b) the diversity of content of Section B and its competitiveness with non-IUCr journals, particularly in the the chemical arena, and (c) the commissioning and inclusion of more high-quality review material.

C08.JR.006 RECENT SECTION C INITIATIVES: AUTOMATIC DATA VALIDATION AND ELECTRONIC PUBLICATION. S.R.Hall Crystallography Centre, University of Western Australia, Nedlands 6907, Australia

The Acta Crystallographic Section C board has instituted a number of initiatives in the past triennium intended to make publishing structural studies more efficient both in terms of author submissions and journal production. These include: the introduction of a CIF-access submission mode as a fast minimum-text option to publishing new structure determinations (introduced in 1997); the explicit specification of data standards for published structural material (with the 1997 Notes for Authors); a briefer full paper publication format (e.g. the removal of coordinate tables); improved access to the Acta published material with increased web services and add-on CIF facilities (in 1997- 8); and, recently, automatic validation and checking of manuscripts, which includes the facility for author submitted validation responses.

The effectiveness of these changes will be discussed in terms of their short and long term objectives. In particular, the reasons for shifting the responsibility for CIF validation from the Acta office to the author will be explained, as well as the overall implications for papers reporting challenging (i.e. difficult!) structural studies. Future expected editorial and publication initiatives will be summarised.

C08.JR.007 ACTA CRYSTALLOGRAPHICA D: CURRENT STATUS AND FUTURE PLANS Jenny P. Glusker The Institute for Cancer Research, The Fox Chase Cancer Center, 7701 Burholme Avenue, Philadelphia, PA 19111 USA

Acta Crystallographica D, devoted to biological crystallography, is now appearing monthly. Its sections include articles on methods of structure determination, crystal characterization and descriptions of structures. We thank the contributors, the co-editors and reviewers who have made this new journal, as of January 1993, a viable publication, and John Helliwell, the Editor-in-Chief, for his continued support and advice. The coeditors and reviewers have worked hard to maintain high standards for this IUCr journal and contributors have been good-humored in responding to requests for revisions. The staff at Chester, particularly Louise Clark-Jones, have then ensured that there is care in the processing of manuscripts and the appearance of the final publication. The handling of manuscripts has been accelerated by the addition of Simon Glynn to the Acta D staff at Chester, so that the time between acceptance and publication is now greatly reduced. Figures in color are provided free of charge, but only when the color adds to the scientific content of the article. In addition, all authors are asked to sign a form attesting to the fact that they have seen the final manuscript; this is done to obviate some problems we have had in the past. Authors of structural papers are required to deposit atomic coordinates and structure factors in the Protein Data Bank. Delay in the release of these data to the scientific community is currently possible, but this is under review by the IUCr Executive Committee. We hope to receive mmCIF files, which contain information on the diffraction experiments and the structure determination, from authors.

Future plans include the solicitation of more reviews and general introductory articles. If you wish to contribute such an article please contact a member of the editorial staff. We have considered whether or not to publish crystallization reports; some scientists applaud their inclusion and others feel that the data should appear in more biological journals or merely in the final structural publication. Our current conclusion has been that they provide important information for the crystallographic community. Your remarks and criticisms are welcome and play an important role in improving this journal.

C08.JR.008 JOURNAL OF APPLIED CRYSTALLOGRAPHY. A.M. Glazer, Clarendon Laboratory, Parks Rd., Oxford, OX1 3PU, United Kingdom.

The Journal of Applied Crystallography is now over 30 years old. The developments in the journal over this time will be briefly reviewed, and a description given of the sections at present offered, including Research Papers, Fast Communications, Cryocrystallography Notes, Laboratory Notes, Computer Programs and Abstracts, Short Communications, Lead Articles, Software Reviews and New Products. In addition from time to time J. Appl. Cryst. publishes Special Issues, and this is an area that I hope will grow. Some statistics relating to production matters will also be presented, which will illustrate the general health of the journal. As retiring Editor of J.Appl. Cryst., I shall point to some of the highlights published, including the seminal work of Rietveld, which has made an enormous impact on the field of powder diffraction, and suggest some ideas for the future development of the journal. Comments and suggestions from the audience will be particularly welcome, especially since a new Editor will be taking over during the IUCr Congress.

C08.JR.009 JOURNAL OF SYNCHROTRON RADIATION : CURRENT STATUS. S Samar Hasnain[1], John R Helliwell[2] and Hiromichi Kamitsubo[3] [1]Synchrotron Radiation Department, CCLRC Daresbury Laboratory, Warrington WA4 4AD, UK, [2]Department of Chemistry, Manchester University, Manchester M13 9PL, UK, [3]SPring-8, JAERI-RIKEN, Kamigori-cho, Hyogo-ken 678-12, Japan

It is now four years since the Journal of Synchrotron Radiation was launched. In this time we have published approximately 500 research articles in over 2500 pages providing a focus for the whole of the synchrotron radiation community.The number of papers published in JSR over the last few years have steadily beeen increasing. For the journal, the main achievement of 1998 was the successful publication of the SRI'97 Proceedings. The papers for this issue were refereed to the usual JSR standards, rather than at the meeting, and we believe that this effort is reflected in the improved quality of the Proceedings which formed the May 1998 issue. Many of the lessons learnt with SRI'97 have been applied to the Proceedings of the XAFS X Meeting, held in Chicago in August 1998, which is to be published in May 1999. This is again fully refereed but is produced as camera ready. We have recently entered into the citation ranking tables and are already ranked third out of thirty seven Journals covering instruments and instrumentation with Rev Scintific Instruments placed FIFTH, NIMS B placed sixth and NIMS A placed 8TH. The review and production times for the journal continue to be rapid. Centralised submission, introduced in 1997, is being used to further improve review times and our current strategy is to cut production times by increasing electronification of the journal. We are currently putting together a SR-structural biology issue (July 1998) to celebrate Dr. John Walkers Nobel prize, which is indeed the first SR related Nobel prize.In 2001, we expect to cover SRI-2000 (Berlin) & XAFS XI (Ako, Japan). We see these special Issues as an important part of increasing the Impact of the Journal, its distribution, readership and thus increasing its subscriptions by the widest possible scientific community.

CC COMPUTING: IMPROVED DATA ACCURACY AND VALIDATION THROUGH SOFTWARE

C09.CC.001 GOODNESS OF FIT-FACT OR FICTION. Peter S. White, University of North Carolina at Chapel Hill, NC, USA, Eric J. Gabe and Gary D. Enright, Steacie Institute for Molecular Sciences, National Research Council of Canada, Ottawa, ON, Canada.

In the last year or so it has become apparent that a number of Acta referees, and editors, have adopted a rather inflexible approach to the application of several criteria for the acceptance of structure papers. This has prompted an examination of some of these quantities in order to clarify our feelings on what constitutes an acceptable structure and whether unbiased quality indicators can be developed. The following comments are based on actual experiences.

1. Goodness-of Fit Values

Ideally, GoF values from correctly weighted least-squares processes approach 1.0. This rarely happens with structure refinement and for good reason. Statistical weights and scattering factors are not perfect, the model uses an inadequate thermal expression and neglects bonding electron effects. Refinement with good data, on well-behaved structures, using F_{obs} or F_{obs}^2, and conventional models yields GoF values in the range 1.5 to 3.0. Adjusting the weights to bring GoF close to 1.0, is more cosmetic than scientific, possibly leads to optimistic esd values and invalidates GoF as a quality control index.

2. An inflexible cutoff for the Nobs/Npar ratio (Rop).

Least-squares is so successful for structure refinement because it is so over-determined. How over-determined is enough? The answer is not a rigid 'If Rop < X, the refinement is no good.'. Papers with Rop > 7 have been rejected, which is unreasonable. More scientific discretion is needed.

3. Insistence on F_{obs}^2 refinement.

Similar remarks apply. Using F_{obs}^2, rather than F_{obs}, is mathematically more correct, but for most structures it makes no significant difference.

Reliance on computer generated 'Alerts' is very tempting, especially to journals with less crystallographic expertise. Acta should ensure that its rules are reasonable and make clear that those rules must be tempered by the informed judgement of referees and editors. At the moment it is unfortunately true that many potential authors are 'voting with their feet'.

C09.CC.002 DATA VALIDATION AT THE PDB. Helen M. Berman, Kyle Burkhardt, Zukang Feng, Shri Jain, Rachel Kramer, Bohdan Schneider, and John Westbrook. Research Collaboratory for Structural Bioinformatics. Rutgers University, 610 Taylor Road, Piscataway, NJ 08854-8087 USA

The new Protein Data Bank (PDB) has created a single integrated system for data deposition, processing, annotation, database management, and archiving. The Auto Dep Input Tool (ADIT, 1), is used for all aspects of structural and experimental validation. For each structure, the following checks are made: nomenclature and numbering, valence geometry, stereochemistry, nonbonded contacts, torsion angle distributions, and structure factors. The ADIT results are sent to the author in a summary letter. These reports, in addition to the output files from NUCheck [2], PROCHECK [3], and SFCheck [4], are provided to the author on a Web page.

These validation reports can also be created without the intervention of the PDB staff. The ADIT Validation server (http://pdb.rutgers.edu/validate/) accepts coordinate and structure factor data to produce the validation reports independent of structure deposition.

The validation features of this system will be discussed.

The PDB is supported by the NSF, DOE, and NIH (NIGMS and NLM)

C09.CC.003 COMPUTING PROGRAMS IN LATTICE DYNAMICS COMPATIBLE WITH USUAL CRYSTALLOGRAPHIC PRACTICE. Carlo M.Gramaccioli, Earth Science Department, University of Milano, Via Botticelli 23, I-20133 Milano, Italy.

Notwithstanding its close relationships to their own discipline, too many crystallographers do not seem to consider lattice dynamics to be an argument of basic importance. Such an importance becomes particularly evident whenever the links between crystallography and solid state physics, or even with arguments of physical chemistry, such as vibrational spectroscopy and thermodynamics, are considered.

Moreover, there has been a growing interest in some results of accurate crystal structure refinement, such as for instance ADPs or “thermal parameters”, as they are still improperly called too often. The neglection of such data is due to their comparatively low accuracy, which at least in part and in most cases depends on their strong correlation with TDS, or with the interpretation of diffraction profiles and the difficulty of distinguishing a peak from its background; there is also notable correlation with other refinable parameters, such as the electron density distribution, scale factors, population parameters, etc.etc.: all these points might lead to some wonder whether ADP’s, just like atomic form factors, rather than from crystal structure refinement, could be derived instead “a priori”, at least in many cases. On the other hand, from the theoretical side there are the difficulty of interpreting the vibrational spectra of crystals, and the insufficient availability of adequate computer programs starting from “usual” crystallographic information: an illustrative point in this respect is the problem of routinely deriving spectroscopic symmetry and Brillouin-zone information from space group operations.

In these respects, computing programs which can be easily used by crystallographers are needed; the feasibilty of the procedure can be illustrated

In practice by a series of examples dealing with molecular and non-molecular crystals, and showing new and interesting possibilities in interpreting thermal motion.

C09.CC.004 *ACTA CRYST. C* DATA VALIDATION AND QUALITY ASSESSMENT: RATIONALE FOR THE CURRENT CRITERIA. J. Albertsson, Department of Inorganic Chemistry, Chalmers University of Technology, S-412 96 Göteborg, Sweden, G. Ferguson, Department of Chemistry and Biochemistry, University of Guelph, Guelph, Ontario, Canada N1G 2W1, S.R. Hall, Crystallography Centre, University of Western Australia, Nedlands 6907, Australia, and A.L. Spek, Department of Crystal and Structural Chemistry, Bijvoet Center for Biomedical Research, Utrecht University, Padualaan 8, 3584 CH Utrecht, The Netherlands.

The rapid growth in the number of crystal structure determinations with the advent of area detectors, coupled with changes in the scientific journal industry in the past decade, are the main reasons for a number of new publication initiatives for *Section C* of *Acta Crystallographica* These include the electronic submission of manuscripts (text and data), faster review and editorial handling procedures, the provision of an electronic publishing mode (CIF-access) and expanded facilities for the online access to the archived published material. Recently, automatic data validation software has been installed so that authors can check their manuscripts prior to submission.

These automated facilities provide not only for comprehensive checking of the completeness and internal consistency of submitted data but also a consistent approach to assessing the quality of the studies accepted for *Section C*. To this end the *Commission on Journals* has set criteria requiring the results of structural studies to meet basic quality and reliability standards. These tests are part of the *CHECKCIF* e-mail or web facilities and they are now a required part of a submission to the journal. The *CHECKCIF* facility applies a complete suite of validation tests and reports to authors any data requirements or standards not met as diagnostic warnings and alerts of varying severity.

This presentation will discuss the reasons for the criteria used to test data standards in *Section C*, as determined by the Commission on Journals and published at

http://www.iucr.org/iucr-top/journals/acta/dv.html.

C09.CC.005 *ACTA CRYST. C* DATA VALIDATION AND QUALITY ASSESSMENT: IMPLEMENTATION AND HANDLING PROCEDURES. M. A. Hoyland and B. McMahon, IUCr, 5 Abbey Square, Chester CH1 2HU, England, A. Linden, Institute of Organic Chemistry, University of Zürich, Winterthurerstrasse 190, CH-8057 Zürich, Switzerland, and S. R. Hall and D. J. du Boulay, Crystallography Centre, University of Western Australia, Nedlands 6907, Australia.

The data validation criteria published for *Acta Crystallographica Section C* (**`http://www.iucr.org/iucr-top/journals/acta/dv.html`**) are applied through the IUCr *checkcif* software suite and the *PLATON* program (A. L. Spek; **`http://www.cryst.chem.uu.nl/platon/`**). Several program authors have made their software available over several years in the development of structure checking for *Acta Crystallographica*, and are gratefully thanked.

Prospective authors are required to assess their structures via *checkcif*, by emailing a CIF to **`checkcif@iucr.org`**, or by web upload *via* the URL **`http://www.iucr.org/iucr-top/journals/acta/c/services/checkcif.html`**. A summary report is returned, listing missing or incorrectly formatted data items, and indicating numerical values that lie outside expected norms. Such outliers are assigned an appropriate level of severity, and the report draws the attention of authors to the need to take action to correct or explain the values, preferably by ensuring details are included in the experimental text. An author unable to eliminate the cause of the outlier, but who believes there is a scientific explanation for the deviation, may write an explanation, using the validation response form supplied with the *checkcif* report, and insert it into the CIF. Such submissions are scrutinised by a 'Validation Coeditor' from the journal editorial board before the normal editorial process begins. The presentation will include a report by the current Validation Coeditor, A. Linden, on how authors react to and benefit from this system.

The IUCr offers different configurations of *checkcif* as a service to other journal publishers and structural database managers.

TC TEACHING: BASIC PHYSICAL CHEMICAL KNOWLEDGE FOR EVALUATING CRYSTALLOGRAPHIC DATA

C11.TC.001 CHEMISTRY AND SYMMETRY IN THE EVALUATION OF INORGANIC STRUCTURES. I.D. Brown, Brockhouse Institute for Materials Research, McMaster University, Hamilton, Ontario, Canada L8S 4M1

The Principle of Maximum Symmetry states that a crystal structure will adopt the highest symmetry possible consistent with the constraints acting in the system. These constraints include the strict requirements of 3-dimensional space as expressed by space group theory and the less strict requirements of chemistry, usually expressed by empirical rules describing the bonding geometry. Because the refined structure does not necessarily satisfy the chemical constraints, the geometry should be checked against the empirical rules of bonding geometry.

The space group may be chosen with too high a symmetry as a result of a failure to recognise the presence of a symmetry-breaking constraint, or it may be chosen with too low a symmetry as a result of failure to recognise a higher symmetry in the bonding topology. These failures can be avoided by an analysis of the bonding topology and geometry.

In inorganic compounds one should always check that the bond topology does not have a symmetry that can be accommodated in a space group of higher symmetry. Further, experimental bond valences determined from bond lengths should match the theoretical bond valences determined from the bonding topology. Differences are expected around cations with anisotropic electron distributions and around cations that are in cavities that are too large, but otherwise such differences, if not arising from an incorrect interpretation of the structure, are evidence of bond strain. The structure should be examined to pinpoint the origin of the strain. If the strain is excessive, the structure may have been refined in a space group with too high a symmetry. In a correctly determined crystal structure all deviations between the experimental and theoretical bond valences should be accounted for.

C11.TC.002 WEB-MODULES FOR THE INTER-ACTIVE TEACHING OF CRYSTALLOGRAPHY. Chapuis G. [1], Hardaker W. [2], [1] Institut de cristallographie, Université de Lausanne, 1015 Lausanne, Switzerland, [2] Information Technology, University of California at Davis, Davis CA 95616, U.S.A.

The teaching of crystallography is greatly facilitated by the use of computers. They open new dimensions in terms of structure visualizations and simulations of diffraction phenomena. Many excellent commercial and freely available software packages exist that the teacher can use to help illustrate his course. The system and hardware requirements imposed by the software, or perhaps by the licensing restrictions, will unfortunately limit the choice or even discourage the use of the software.

The new possibilities offered by the ubiquitous web can avoid this serious drawback. The Java programming language allows platform-independent development of applications that can be directly accessed from web browsers. Present web browsers are all able to handle "java applets", which consist of small Java applications that can be used to illustrate specific aspects in a lecture or a conference. From a computer laboratory or from home, the student can have access to the same software demonstrations as the teacher and thus can complete his training and formation according to his own schedule.

We have developed a series of Java applications with the aim of illustrating some basic concepts of crystallography: point group symmetry, space group symmetry and the elements of crystal diffraction.

Currently, a few websites dispersed all over the world offer already a selection of applets illustrating additional aspects of crystallography. It is thus very easy to include pointers referring to these sites in order to extend the possibilities of training offered to the students.

C11.TC.003 CRYSTALLOGRAPHIC TOOLS FOR CHEMISTS. R. Cooper, K. Prout, D. Watkin, Chemical Crystallography Laboratory, 9 Parks Road, Oxford, OX1 3PD, UK, and F. Allen, S. Motherwell, CCDC, 12 Union Road, Cambridge, CB2 1EZ, UK.

Modern diffractometers allow users to collect 1 to 3 data sets per day and routine structures can be solved and refined by even relatively inexperienced crystallographers. To ensure that analyses are optimal, techniques have been devised to detect problems with the structure and to assist the user in correcting or understanding the problems.

Signalling problems with an analysis at the publication stage is inefficient and ineffective. To ensure optimal results, problems should be detected and corrected as the analysis proceeds. Using the Crystals program, features of the structure can be verified with observations derived from the Cambridge Structural Database, or against a chemist's idea of the two-dimensional structure. Values that are going to cause failure or require explanation when submitting the structure to journals or databases can be checked.

Tools are provided to enable the user to resolve problems during analysis:

A 3D model of the structure is available at all times following structure solution. The model can be used to inspect, edit and analyse the structure, to display graphical information such as existing restraints and deviating bond lengths, and to initiate atom or fragment based commands.

Disorder can be investigated using generalised Fourier sections through the volume of interest, and can be modelled by constraining or restraining physical quantities such as occupancies, and thermal parameters. The program will detect if any axis of a thermal ellipsoid has become too large and tools can be used to split the elliptical atom into two new atoms at the foci of the original ellipse. For more complicated disorder a diffuse electron density can be modelled over non-atomic shapes.

Adding restraints to the refinement is often necessary when there is insufficient data to refine the model. Tools are available to quickly restrain any distances or angles in the structure, and values and weights for the restraints can be suggested from the information obtained from the CSD.

C11.TC.004 THE IMPACT OF TEACHING SCHOOLS ON THE DEVELOPMENTS OF CRYSTALLOGRAPHY IN THE THIRD WORLD COUNTRIES. Karimat El-Sayed, Physics Department, Faculty of Science, Ain Shams University, Cairo, Egypt.

The post-graduate students and even the University Lecturers of the developing countries are not usually in a good scientific atmosphere. This is mainly due to the lack of; equipments, scientific books, Journals, research grants, attending conferences and lastly having contacts with International Scientists and Experts. Crystallography is the most affected subject in this unhealthy scientific climate because it is considered by the policy makers not to be a real subject. Teaching Schools and Workshops are the only methodologies which could counteracts all these mentioned difficulties present in the Third World Countries. They are the only means by which international outstanding lecturers can come to teach the most developed techniques and advanced topics to researchers. They allow the

students to discuss topics at the frontiers of research and to know the most recent applications of crystallography in material science, chemistry, biology, etc. They allow the researchers to have the school and Workshops proceedings which counteract the books deficiency. Several Schools and Workshops were held in Egypt, the programs of each Schools were designed in accordance with the need of the researchers and the goal which will be achieved in each stage. These items will be discussed in details in the given paper.

C11.TC.005 TEACHING STRUCTURAL CRYSTALLOGRAPHY: SOME SIMPLE CONCEPTS USED IN TEACHING COMMISSION SCHOOLS. Jenny P. Glusker, The Institute for Cancer Research, The Fox Chase Cancer Center, 7701 Burholme Avenue, Philadelphia, PA 19111, USA

Some tips on methods of teaching crystallography will be provided for those giving courses on the solid state and the structures of ions, molecules and crystals. The results of X-ray diffraction studies of crystalline materials are simple to comprehend if three-dimensional models are built. The methods used to arrive at the results that enabled such models to be built are, however, complex; the teacher needs to pay careful attention to the individual conceptual needs of the students when describing them. One of the most difficult areas for a teacher of structural crystallography to describe and explain is the connection between the intensities in the X-ray diffraction pattern and the electron density map that results, that is, the Fourier transform, what it is and why it is applicable for this transformation. Some students readily understand the mathematical equations used, while others do better with descriptions of waves and optical analogies. Some examples of methods used to teach molecular structure determination at IUCr Teaching Commission Schools will be provided. In this I have been helped by Professors Ken Trueblood, Joel Sussmann, Miriam Rossi, Mitchell Lewis, and the text "X-ray Analysis of Crystals" by J. M. Bijvoet, N. H. Kolkmeyer and C. H. McGillavry.

Some of the concepts to be addressed are the Patterson function (including convolutions), the Fourier transform, precision versus accuracy, and the term "resolution." Their significance in small-molecule and macromolecular structure determinations will be addressed with some examples of structures and intermolecular interactions.

This work was supported by a grant CA-10925 from the National Institutes of Health, US Public Health Service.

C11.TC.006 THE IMPORTANCE OF ADEQUATE KNOWLEDGE OF PHYSICAL CHEMICAL ARGUMENTS IN CRYSTALLOGRAPHY. Carlo M. Gramaccioli, Earth Science Department, University of Milano, Via Botticelli 23, I-20133 Milano, Italy.

Active participation together with other groups of specialists in other disciplines is of utmost importance for crystallographers, in order not to be considered as mere technicians. Such a participation especially concerns either a careful planning of the experiments to be carried out on a selected group of substances, or also the interpretation of the data as they have been obtained from the solution and refinement of crystal structures.

In such a respect, in spite of the qualification of crystallography as a discipline with a sophisticated mathematical and physical background, in too many crystallographic papers only a superficial knowledge of physical chemical arguments can be noticed frequently. Such a lack of detailed basic general knowledge in particular concerns spectroscopy, thermodynamics, or also quantum mechanics.

For instance, there has been too little emphasis on the relationships of symmetry as it is used by spectroscopists with the corresponding concepts in crystallography: this point has often been one of the major drawbacks concerning a correct interpretation of vibrational spectra of crystals; at the same time, crystal structure modelling would be dramatically improved if not only the “static” crystal structure data are satisfactorily interpreted and reproduced, but thermodynamic properties could be reproduced as well at different temperatures.

Unfortunately, too many models currently used by crystallographers contain fundamental errors, such as the interpretation of ionic inorganic structures using molecular models, or the neglection of zero-point effects in considering the vibrational energy and the amplitude of atomic motion, or even the interpretation of the amplitude of vibration of certain groups or molecules more or less exclusively based on Raman- or infrared spectra.

For these reasons, the organization of adequate schools for crystallographers dealing with these subjects would be strongly recommended, as an argument of primary importance.

C11.TC.007 THE IMPORTANCE OF X-RAY DIFFRACTION IN THE REAL WORLD OF REAL PEOPLE. Michael Laing School of Chemistry, University of Natal, Durban 4041, Republic of South Africa

For many science students, X-ray crystallography is the tough course to be avoided. For most chemists, it is the mysterious source of information about molecular structure and bond lengths. It is the task of the teacher to show the average science student the enormous value of X-ray crystallography and its power to supply information that will help the scientists to solve problems. In particular, the student needs to learn how the identity of the crystalline phases in a solid can be used together with chemical knowledge to explain chemical phenomena that would otherwise be intractable problems.

For example, X-ray diffraction can help build better roads (by identifying mineral species in the soil); help urologists to heal their patients who suffer from calculi (by identifying the crystalline components of the calculi and therefore their cause); help improve efficiency in a platinum metal refinery (by identifying the intractable solid phases and thus indicating changes in processes to dissolve the solids); characterise fossils of ancient hominids (by determining the components in the bone and surrounding breccia); play a vital forensic role for the police (anything from identifying paint samples to determining the temperature of a fire).

The data required in each of these examples is easily collected but to evaluate it requires a sound understanding of the chemistry relevant to the problem. Teaching this step is the challenge to the chemical crystallographer.

C11.TC.008 THE USE OF THE MOLECULAR GRAPHICS PROGRAM TITAN IN TEACHING X-RAY CRYSTALLOGRAPHY. Jim Simpson and Keith A Hunter, Department of Chemistry, University of Otago, P.O. Box 56, Dunedin 9001, New Zealand.

The TITAN molecular graphics program was developed as a readily accessible graphical tool to allow classes of undergraduate students to experience the solution and refinement of a small molecule crystal structures, using the widely available SHELX programs. Over the past several years the program has evolved to give an easy to use and reasonably intuitive tool for the display and manipulation of molecular structures from the output of the SHELXS and SHELXL programs. Input from students using the program has been important in this development.

This presentation will highlight some features of the program, from a teaching perspective, and the experience of the presenting author in using the program in an undergraduate teaching situation.

C11.TC.009 TEACHING THEORETICAL AND PHYSICAL CRYSTAL CHEMISTRY FOR CRYSTALLOGRAPHERS OF MOSCOW UNIVERSITY. Vadim S.Urusov, Department of Crystallography and Crystal Chemistry, Geological Faculty, Moscow University, 119899 Moscow, Russia

Teaching in theoretical and physical crystal chemistry for the students which are specialized in crystallography of minerals is divided into two stages. First of them is a familiarity with foundations of theoretical crystal chemistry for all students of geochemical division during the first two years of education. It involves an introduction in the theory of chemical bonding in crystals, characterization of crystal chemical properties of atoms, principles and rules of a structure type stability, structural homology, polymorphism and polytypism, isomorphous substitutions in crystals.

The second stage is training in the methods of theoretical and physical crystal chemistry for students-crystallographers of the last two years of education. This consists of two parts: 1)a general introduction to symmetry and crystal chemical constraints on the structures of inorganic solids, 2)a closer inspection of the methods and approachs to prediction of probable structures of minerals and inorganic crystals. The latter involves both the prediction of bonding topology and refinement the topological description by modern methods of the least squares fitting to the expected geometry and lattice energy minimization with semi-empirical and ab-initio potentials. The course of lectures is supplemented with the practical training in using the crystal structure databases and programm packages.

HP HIGH PRESSURE

C12.HP.001 HIGH-PRESSURE, ANGLE-DISPERSIVE, X-RAY POWDER DIFFRACTION USING A LABORATORY SOURCE. J. Haines and J. M. Léger, Laboratoire de Physico-Chimie des Matériaux, C.N.R.S., 1, place Aristide Briand 92195 Meudon cedex, France.

A laboratory-based, high-pressure, angle-dispersive, x-ray powder diffraction experiment will be described. The equipment consists of an 800 W molybdenum microfocus tube, x-ray capillary optics and imaging plates. Two high-pressure experiments using diamond anvil cells can be performed simultaneously using the two point foci of the tube. The use of x-ray capillary optics results in a five-fold increase in flux with respect to traditional collimation. The diffraction profiles obtained upon integrating the 2D images can be routinely used for Rietveld refinement. Comparison will be made between refinements performed using data from this source and synchrotron data. The need to minimize deviatoric stress through the use of hydrostatic, pressure-transmitting media and annealing at high temperature will be emphasized. A large number of high-pressure, x-ray diffraction experiments can be performed in the laboratory and some examples concerning oxides, oxynitrides and semiconductors will be presented.

C12.HP.002 X-RAY IN SITU STUDIES OF SOME EARTH'S MATERIALS AT HIGH P-T CONDITIONS WITH IN-HOUSE FACILITIES. L. S. Dubrovinsky, N. A. Dubrovinskaia, S. K. Saxena Theoretical Geochemistry Program, Department of Earth Sciences, Uppsala University, Villavägen 16, 752 36 Uppsala, Sweden

Experimental studies of geophysically important materials at high pressures require in situ x-ray diffraction. It is practically the only method which provides direct information on phase relations and structures. We developed in-house X-ray facility which allows us to collect diffraction patterns in megabar pressure range at temperature to 1000 C. We obtain powder X-ray diffraction data with a Siemens X-ray system consisting of a Smart CCD Area Detector and a direct-drive rotating anode as X-ray generator. With the capillary optic installed, a high-intensity focus of X-rays is produced at the sample position, and its width is controlled by the choice of field aperture. This system allows us to obtain X-ray beam from 85 mu FWHM with 95% of initial intensity (intensity after shutter) to 35 mu FWHM with 25% of initial intensity. Small size of the X-ray beam and high sensitivity of CCD area detector open the way to study phase transitions and elastic volumetric properties of solids up to 100 GPa at room temperature using different types of high-pressure cells (Mao-Bell, Merril-Basset etc.) and thermal expansion, phase transitions and chemical reactions of solids up to 3600 K in inert atmosphere at ambient pressure. In-house x-ray facilities were used to study, for example, the phase transition in iron and interaction between iron and MgO. Using our in-house facilities we obtained new X-ray in situ data on thermal expansion of refractory metals (Cr, Ta, W) and oxides (MgO, HfO2, Y2O3) and thermal expansion, phase relations and compressibility of alloys and compounds in Mg-Si-O, Fe-Al-C, Co-Ti-C , and Co-W-C systems.

C12.HP.003 THE LIMITS OF ACCURATE HIGH-PRESSURE SINGLE-CRYSTAL X-RAY DIFF. STUDIES ON A LAB SEALED-TUBE SOURCE. D.R. Allan Department of Physics and Astronomy, University of Edinburgh, Edinburgh, UK

Single-crystal x-ray diffraction is the longest established technique for obtaining truly accurate crystallographic information from samples held at high pressure, and it still provides the best structural data for a whole range of contrasting systems - despite some recent advances in powder-diffraction techniques using synchrotron and neutron radiation. Here, as well as outlining basic high-pressure single-crystal techniques, examples will be given of work on weakly scattering systems (such as boron and small organic molecules) at the very limit of what can be achieved successfully on a laboratory-based sealed-tube source. The results of some of this work will be compared with parallel studies conducted on station 9.8 at the Synchrotron Radiation Source, Daresbury.

C12.HP.004 OPTIMIZING MEASUREMENTS OF EQUATIONS OF STATE WITH IN-HOUSE SINGLE-CRYSTAL X-RAY DIFFRACTION. R.J. Angel, Bayerisches Geoinstitut, Universität Bayreuth, D95440 Bayreuth, Germany.

Equations of state can be determined by static compression of crystals in a diamond anvil cell, with the lattice parameters (and hence volume) determined by diffraction.

With special precautions, the current achievable precision in unit-cell parameters is about 1 part in 30-60,000, corresponding to a precision in unit-cell volumes of 1 part in 10-20,000. With this precision, pressure can be determined from an internal diffraction standard, such as quartz to better than 0.01 GPa over the pressure range 0-10 GPa. At this level of measurement precision, the resulting precision in the equation of state parameters of the sample crystal depends upon the ratio of its bulk modulus to the pressure range over which the data are collected, and only weakly upon the number of data points.

The precision of in-house X-ray diffraction experiments are therefore limited by a number of factors. Temperature in the X-ray enclosure must be controlled to better than 1 K in order for thermal expansion not to contribute significantly to data scatter. This sensitivity to temperature is also the reason for using an internal diffraction standard to measure pressure. The wavelengths and relative intensities of the components of the incident X-ray beam must remain constant; wavelengths to much better than 1 part in 50,000. This argues against the use of monochromators, or synchrotron sources. The ultimate limit to the precision to be

achieved in the future is the maximum pressure to which single-crystals can be compressed hydrostatically in a diamond-anvil pressure cell; with current techniques 10 GPa is routine, but higher pressures require exotic pressure media of uncertain properties.

C12.HP.005 EQUATION OF STATE MEASUREMENTS BY BRILLOUIN SCATTERING AT HIGH P AND T AND TEMPERATURES. Jay D Bass, Stanislav V Sinogeikin, Department of Geology, University of Illinois, 1301 W. Green St., Urbana, Illinios 61801 USA

Brillouin scattering provides information on the P-V equation of state. It is an inelastic light scattering technique, similar in many ways to Raman scattering, but the quantities which are measured in a Brillouin experiment are the compressional and shear elastic wave velocities (known in the Earth sciences as P and S waves). The elastic wave (sound wave) velocities are in turn related to the bulk modulus, which by definition gives the P-V relation at a given P and T. The experiment can be performed on single crystals (the most common application), or in favorable instances on polycrystals. The sound velocities for single crystals are generally a strong function of crystallographic direction. That is, they are anisotropic. By measuring the directional dependence of sound velocity, the single-crystal elastic moduli are determined. It is critical to know the crystallographic orientation of a sample throughout the experiment and this is determined using single crystal x-ray methods. Brillouin scattering experiments are being performed at high P and T using diamond anvil cells and high temperature furnaces. Diamond cells are well suited for this type of work, because all that is required for a Brillouin experiment is to be able to see the sample. We will discuss the special considerations needed for high P and T Brillouin experiments, and we will describe a high temperature furnace we designed that is suitable for many types of high temperature scattering experiments with single crystals, including x-ray scattering.

C12.HP.006 POSSIBILITIES AND LIMITATIONS OF THE APPLICATION OF THE HIGH-PRESSURE MÖSSBAUER EFFECT TECHNIQUE. M Abd-Elmeguid , II. Physikalisches Institut, Universität zu Köln, Zülpicher Straße 77, 50937 Köln, Germany.

The high pressure Mössbauer effect technique is a powerful tool which allows the determination of pressure-induced changes of electronic and magnetic properties of systems containing Mössbauer isotopes. In this contribution I will give a brief review on possibilities, limitation and the experimental problems of using these technique.

C12.HP.007 SEVERAL ASPECTS OF EXPERIMENTAL TECHNIQUES AT MBAR REGION K.Amaya Graduate School of Engineering Science, Osaka University, 1-3 Machikaneyama, Toyonaka, Osaka, Japan.

Techniques to produce ultra-high pressure exceeding 200GPa and to measure electrical resistance and magnetization of the sample confined in the pressure cell (DAC) are reviewed. Varieties of pressure-induced superconductivity observed in our laboratory are also reviewed. Experimental difficulties and possibilities toward higher pressure are discussed.

JMR THE MONTEATH-ROBERTSON SYMPOSIUM

JMR.07.001 FROM AROMATIC HYDROCARBONS TO VIRUS STRUCTURE. Michael G. Rossmann, Department of Biological Sciences, Purdue University, West Lafayette, IN 47907-1392, USA

A short history will be given of the technical changes that have occurred in structural crystallography between 1953 (when I entered J.M. Robertson's laboratory) and today. In the 50's, the Robertson Sorting Board and Beevers Lipson Strips were being used for structure determinations that had short cell axes, thus permitting the resolution of atoms when viewed in projection. Compounds suitable for crystallographic studies were usually limited to those with less than about 30 or 40 non-hydrogen atoms. Electronic computers, introduced in the late 50's, made possible routine three-dimensional analyses. The first low resolution protein structures were solved in Cambridge using home-built computers. Model building was dependent on hand-drawn electron density sections. The Richard's optical comparator ("Fred's Folly") was a tremendous advance in model building. This was the basis for the subsequent electronic "Richard boxes" - computer graphics. The techniques for solving the phase problem increased in parallel with the ever-increasing power of computers. Synchrotron X-ray sources improved both the quality and speed of data collection. The rate of protein structure determinations has increased exponentially in the 80's and 90's. The first spherical virus structures were solved in the late 70's. Now there exist numerous structures of viruses and their complexes with receptors and neutralizing antibodies. The power of electron microscopy has also been increasing to allow a gradual merging with crystallographic results. Some recent structural investigations of viruses will be discussed. In some instances, viruses with over 50 million Daltons molecular weight have been investigated to atomic resolution.

JMR.07.002 FROM MOLECULES TO PHYSICAL PROPERTIES. S. C. Abrahams, Physics Department, Southern Oregon University, Ashland, OR 97520, USA.

Selection of Glasgow as the venue for the second IUCr Congress organised in the UK is a measure of the high esteem in which J. Monteath Robertson, founder of the Glasgow school of crystallography, is held. This presentation will sketch a series of interactions at several levels with JM, as he was known to his students, through a variety of interconnected themes. The first starts with an association that began in 1942 when he came to Glasgow as a newly appointed Professor and the writer arrived nearly simultaneously as a first year undergraduate student. A separate motif traces the evolution of interests that originated in the X-ray diffraction study of organic molecules under JM’s guidance and the course of their development under the early application of digital computers to diffraction results. The availability of neutrons from a graphite reactor led first to a need for automating the manual diffraction measurements that were normal at that time and then to an associated requirement for improved understanding of the uncertainties in the resulting quantities. The related question whether structure determination is better regarded as an end or a means subsequently initiated investigations into the relationships between crystal structure and material physical properties implied by the present title. A further theme considers the influence that several early developments in our field have had both on methods in use today and on new materials, including the discovery of some materials with physical properties of potentially high technological value. Another introduces additional founders of our branch of science and their connections to JM in addition to outlining some links between him and the IUCr. The remaining theme relates JM’s influence on his graduate students to the range of crystallography they

subsequently came to encompass. Among the results anticipated from this evening discourse are both the evocation of a personality and an enhanced appreciation of particular physical properties.

JMR.07.003 CHEMICAL CRYSTALLOGRAPHY: FROM THEN TILL NOW. Jack D. Dunitz, Organic Chemistry Laboratory, Swiss Federal Institute of Technology, ETH-Zentrum, CH-8092 Zurich, Switzerland.

In those days we knew practically every crystal structure that had ever been determined, who had done it, how had it been solved. Today no one can keep pace with the world wide output of crystallographic data, nor would anyone want to. In JMR's time, to be a chemical crystallographer, you needed a good memory, today you need the Cambridge Structural Database (CSD) and the Protein Data Bank (PDB). Robertson's Glasgow school cannot completely disclaim responsibility for this transition. Its graduates spread out over the world. Some of the ways in which crystallography influenced the development of chemistry will be briefly sketched.

JMR.07.004 PROTEIN CRYSTALLOGRAPHY IN GLASGOW. N.W. Isaacs, Department of Chemistry, University of Glasgow, Glasgow G12 8QQ, UK.

Since the appointment in 1942 of J. M. Robertson to the Gardner Chair in the Chemistry Department, the University of Glasgow has been a centre of excellence in crystallography. A roll call of the academic and research staff and students who have passed through the department shows a large number of outstanding crystallographers. George Sim, Robertson's successor, was instrumental in bringing protein crystallography to Glasgow with the appointment of Ian Swan to a lectureship in 1975. Ian's untimely death a few years later interrupted this initiative and it was not until 1989, that a protein crystallographic laboratory was re-established. The Robertson Protein Crystallography Laboratory has flourished in the past ten years, with the structures of human chorionic gonadotropin and the integral membrane light-harvesting complex among its notable achievements. With strong links to research in the biological sciences in the University, the programme of work in the laboratory covers broad range of problems. This presentation will describe some of this ongoing work.

LATE ABSTRACTS

The following abstracts were received or processed after the Abstract Book went to print.

M08.AA.005 PROTEIN FOLDS, FUNCTIONS AND EVOLUTION. J.M. Thornton, A. Kasuya, R. A. Laskowski, D. Milburn, C. A. Orengo, and C. Porter, Department of Biochemistry and Molecular Biology, University College London, Gower Street, London, WC1E 6BT, England, UK

As more gene sequences are determined, the demand for better methods to predict protein function from sequence grows. Currently the only reliable approach is to predict function by recognising sequence and/or structural homology to a related protein, whose function is known. Recognising close relatives is easy using standard algorithms, but recognition of more distant homologues becomes more difficult as sequences and structures diverge. Recent methods have improved recognition by using family information and iterative scanning to build up a 'sequence profile'. Our interest lies in the relationship between protein sequence, structure and function. An overview will be presented of our current knowledge of the universe of protein structures, and how sequences, structures and functions evolve. In particular, we will consider the relationship between fold and function using our classification scheme of protein structures called CATH (1). Every structure includes much information on detailed interactions, involved in biological function, yet very little of this information is used in genome analysis. We have therefore developed some software tools which seek to improve the annotation of sequences by the structural and functional information, especially regarding inter- and intra-molecular interactions. This resource is available on the web at http://www.biochem.ucl.ac.uk/bsm. Various methods to extract and classify functional information from structural work will also be discussed (3, 4).

P12.04.018 CRYSTAL STRUCTURE OF SIMIAN IMMUNODEFICIENCY VIRUS INTEGRASE CONTAINING THE CORE AND C-TERMINAL DOMAIN (RESIDUES 50-293) – AN INITIAL GLANCE OF THE VIRAL DNA BINDING PLATFORM. Zhongguo Chen, Youwei Yan, Sanjeev Munshi, Ying Li, Joan Zugay-Murphy, Bei Xu, Marc Witmer, Peter Felock, Abigail Wolfe, Vinod Sardana, Daria Hazuda, Emilio A. Emini, and Lawrence C. Kuo. Department of Antiviral Research, Merck Research Laboratories, West Point, Pennsylvania 19486-0004.

The crystal structure of simian immunodeficiency virus integrase that contains in a single polypeptide the core and the C-terminal deoxyoligonucleotide binding domain (DBD) has been determined at 3Å resolution. The cell constants of the crystal obtained at pH 5.5 are *a* =79.57Å, *b*=100.0Å, *c* =150.5Å and $\alpha=\beta=\gamma=90°$ in the space group $P2_12_12_1$ with Z=4. Four integrase core domains and one DBD are found to be well defined in the asymmetric unit. The other three DBD domains are disordered and cannot be located. The final R-factor is 0.232.

The four core domains are grouped in the asymmetric unit as two dimers related by a 90° rotation about and a 23Å translation along the *c*-axis. Each has the same overall fold and inter-domain interactions as seen for the human immunodeficiency virus-1 (HIV-1) integrase dimer [1]. The C_α tracing of the DBD domain is also similar to the reported DBD structure from HIV-1 integrase [2]. However, the dimeric form seen in the NMR structure cannot exist as related by the non-crystallographic symmetry in the SIV integrase crystal.

In the 2-domain crystal structure, the segment encompassing residues 114-121 assumes the same position as seen in the integrase core domain of avian sacoma virus and HIV-1 crystallized in the absence of sodium cacodylate [3, 4]. The flexible loop in the active site, composed of residues 142-153, remains incompletely defined, but the location of Glu152 is clearly defined; its side-chain points toward Asp64 and Asp116 to form a triad. The residues from 210-218 that link the core and DBD domains can be traced as an extension of α6 helix from the core with a short gap at residues 216-218. The two flexible loops of the DBD, residues 228-236 and residues 244-249, are much better fixed in the crystal structure with the former in the immediate vicinity of the flexible loop of the core domain. The interface between the two domains encompasses a surface area of ~1,500Å^2. Residues from both domains purportedly involved in DNA binding are narrowly distributed on the same face of the molecule. They include Asp64, Asp116, Glu157 and Lys159 from the core and Arg231, Leu234, Arg262, Arg263 and Lys264 from the DBD. A model for DNA binding is proposed to show that the DNA bridges the two domains by tethering the 228-236 loop of the DBD and the disordered loop of the core.

P07.FF.008 AN UNEXPECTED DISCREPANCY IN THE ASYMMETRIC UNIT OF ISOCYANATO-(VINYL-IMIDAZOLE)-COBALOXIME. T. Wagner, Department of Pharmacology, University of Virginia, Charlottesville, USA. N. Knur and U. Englert, Institut für Anorganische Chemie, RWTH Aachen, Germany.

Bis(dimethylglyoximato)isocyanato(3-vinyl-imidazole) cobalt(III) crystallizes in the monoclinic space group $P2_1/c$ with two molecules in the asymmetric unit. As one would expect, the molecules are very similar with respect to their bond lengths and angles. There is, however, a striking difference in the orientation of the planar axial base. In one case the plane through the five ring atoms of the imidazole is almost parallel to the midpoints of the carbon-carbon bonds in the glyoximato moieties while in the other it is approximately perpendicular. This indicates that the conformation of the base in this type of compounds is a soft degree of freedom which may easily be adjusted to assure packing efficiency during crystallization. A survey of the literature suggests a rather electronic nature for this feature. If the aromatic ligand is a pyridine derivative, the arrangement is close to perpendicular in all cases whereas it is almost parallel for ligands such as imidazole [1].

Our presentation will address three different aspects of this unusual crystal structure:

We are currently analyzing if the more than 70 cobaloximes with an aromatic base in at least one of the axial positions found in the Cambridge Structural Database exhibit the preferences described more than a decade ago for a much smaller number of compounds [1].

A minimization of both molecules with semiempirical methods should verify our hypothesis that one of them is indeed an energetic minimum, but the difference to the other conformation is small enough to be overcome even by weak forces like those exerted by the crystal surroundings.

A comparison of the lattice energies of our experimental and a hypothetical structure with both molecules in the same conformation reveals that the packing of identical molecules is less favorable in terms of energy as well as space filling.

P05.04.015 STRUCTURAL ASPECTS OF AGONISM AND ANTAGONISM IN OESTROGEN RECEPTOR ISOFORMS. A.C.W. Pike, A.M. Brzozowski, J. Walton, and R.E. Hubbard, Structural Biology Laboratory, Chemistry Department, University of York, York YO10 5DD, U.K., T. Bonn and M. Carlquist, Karo Bio AB, NOVUM, S-14157 Huddinge, Sweden and J-Å. Gustafsson, Karolinska Institute, NOVUM, S-14186 Huddinge, Sweden.

The oestrogen receptor (ER) is a ligand-activated transcription factor. The recent unexpected discovery of a second ER, termed ERβ, has provoked extreme interest in the respective roles of the two ER isoforms in oestrogen action. ERα (classical ER) and ERβ share modest overall sequence identity but differ substantially in tissue distribution, ligand binding and in transactivation properties.

We have determined the crystal structures of the ligand-binding domain of ERβ (ERβ-LBD) in complex with the phytoestrogen genistein and the anti-osteoporosis agent, raloxifene at resolutions of 1.8Å and 2.3Å respectively. Comparison of these structures with liganded ERα-LBD [1] give a unique insight into the structural principles that underlie ligand recognition and selectivity, cavity plasticity and recruitment of coactivators by the respective receptor isoforms. Each ligand interacts with a unique set of residues within the hormone binding cavity. As in ERα, the bulky sidechain of the antagonist raloxifene protrudes from the cavity and physically prevents the alignment of the activation helix (H12) over the bound ligand. In contrast, genistein is completely buried within the protein and binds in a manner similar to that observed for the natural hormone, 17β-oestradiol. However, in the ERβ-genistein complex H12 does not adopt the distinctive agonist position. Such a sub-optimal alignment is consistent with genistein's partial agonist character in ERβ and demonstrates how ER's transcriptional response to certain bound ligands is attenuated.

P13.22.004 FORMATION OF QUASICRYSTALLINE D-AL-NI-CO BY SOLID STATE REACTIONS OF MULTILAYERS PREPARED BY PLD. S. Braun [1], D. Meyer, P. Paufler [2], [1] Fraunhofer Institute Material and Beam Technology Dresden, Germany, [2] Institute of Crystallography and Solid State Physics, Technical University Dresden, Germany

Thin layers of the decagonal phase of the Al-Ni-Co system were synthesized by Pulsed Laser Deposition (PLD). The short range order of these layers was characterized by Extended X-Ray Absorption Fine Structure (EXAFS) measurements. It is shown that single-phased decagonal structures can be formed by solid state reactions of PLD prepared multilayers. A 10-period Co/Al/Ni multilayer has been fabricated under UHV conditions (low 1.0e-8mbar), using the first harmonic of a Nd:YAG pulsed laser (tau=10ns, lambda=1064nm). After determination of deposition rates of each material, the element composition of the layer stack can be adjusted very exactly, because of the high precision of the PLD process. Finally, the formation of the decagonal phase was reached by post-annealing of the multilayer at 700°C for 5 hours. The five-fold symmetry of the structure is shown in a TEM micrograph cross-section. Specular X-ray diffraction investigations indicate that the periodic direction of the decagonal structure is aligned perpendicularly to the substrate surface. This is in correspondence with known results of the isotypic structure of decagonal Al-Cu-Co. The comparison of the EXAFS measurements of the quasicrystalline thin layers with a quasicrystalline reference sample shows a very high level of similarity. Therefore both the short range order and the long range order (responsible for the x-ray diffraction pattern) of the produced quasicrystalline samples were found to be equivalent to the short and long range order in a quasicrystalline reference sample.

P13.OA.005 CRYSTAL STRUCTURE OF THE PROTEIN DISULFIDE BOND ISOMERASE, DSBC, FROM *ESCHERICHIA COLI*. A. A. McCarthy, P. Haebel, E. N. Baker, and P. Metcalf, University of Auckland

Protein disulfide isomerases are essential for the correct pairing of disulfide bonds during the folding of proteins with multiple disulfide bonds *in vivo*. The best characterised *E. coli.* disulfide bond isomerase, DsbC, is one of seven gene products (DsbA-G), essential for disulfide bond formation in the periplasm. The crystal structure of DsbC, determined by MAD phasing and refined to 1.9Å also contains a thioredoxin fold. The thioredoxin sub-domain contains the redox-active disulfide bond at the N-terminus of the first helix and a *cis*-proline abutting the active site disulfide bond, similar to other thiol/disulfide oxidoreductases. Arg125 observed near the active site is ideally positioned to stabilise a negatively charged thiolate form through both a direct charge stabilisation and an enhancement of a helical dipole stabilisation effect. An acidic/basic motif comprised of Arg125 and Asp95 was observed in the vicinity of the more N-terminal and solvent exposed active site Cys and may participate in the catalytic mechanism of DsbC. Prominent clefts or grooves observed near the active site are notably absent in DsbC. DsbC appears to have evolved from a simple thioredoxin fold into a two-domain structure to facilitate the complex conformational changes necessary for protein disulfide isomerisation.

P06.11.035 X-RAY DIFFRACTION STUDIES OF CdF_2/CaF_2 SUPERLATTICES ON Si(111). R.N.Kyutt, N.S.Sokolov, S.M.Suturin, Ioffe Physico-Technical Institute, St.Petersburg 194021, Russia, J.Harada, K.Inaba, X-ray Research Laboratory, Rigaku Co, Tokyo 196-8666, Japan

Structural parameters of CdF_2/CaF_2 superlattices (SLs) grown on Si (111) substrates by MBE -method with various periods (from 2 to 40 nm) and total thickness from 100 to 350 nm are studied by double and triple crystal X-ray diffractometry. The measurements have been carried out in a wide range of the diffraction conditions including Bragg and Laue diffraction as well as in-plane geometry. By using the semikinematical approach, simulation of rocking curves has been performed and main parameters of the SLs have been determined.

The data obtained in different geometries allowed estimation of the contribution of three periodic distributions (out-

of-plane, in-plane interplanar spacing and scattering ability) to the resulting diffraction curves. Well-pronounced superstructure reflections (up to 5th order) and thickness fringes indicated high periodicity of the SLs and flatness both surface and SL/Si(111) interface. For short period SLs (d<10-20nm) narrow ω-curves (~10 arc.sec) showed their very high structural perfection.

However for the SLs with longer periods, triple crystal mapping and ω-scan cross sections showed noticeable distortion of the diffraction patterns. Atomic force microscopy measurements revealed multilayer columns on the surface of these structures. Depending on the SL period, the columns covered 10-20% of the surface. Coherency of the columns with the silicon substrate and their possible origin are discussed.

P09.06.032 FATS CHALLENGE CRYSTALLOGRAPHY. H. Schenk, R. Peschar, A.J. van Langevelde and K.F. van Malssen, Laboratory for Crystallography, University of Amsterdam, Nieuwe Achtergracht 166, 1018 WV Amsterdam, The Netherlands.

Triacylglycerols (TAGs) are long-chain hydro-carbon compounds with specific difficulties for crystallographers. The typical polymorphism (six different polymorphs are known) and the domination of diffraction by the chains make structure determination extremely difficult. The growth characteristics is the first problem to be overcome, secondly the measurements hare handicapped by the three very different crystal axes and finally the structure remains a problem in itself. As a result there were 3 crystal structures known only. The current research project took the challenge and tackled part of these difficulties. Controlled solidification resulted in single crystals of various TAGs. Crystals of tripalmitin appeared good enough for accurate data collection, resulting in the crystal structure of the largest TAG so far. Extreme difficulties in growing single crystals in other phases than the ß phase, or from other TAGs than mono-acid even-numbered TAGs, made the help of High Resolution Powder Diffraction at BM16 of the ESRF necessary. Using the combined information of series of TAGs, molecular modeling revealed information about the crystal structure of the ß' phase. Finally, the polymorphic behavior, being of large practical importance in food industry, has been studied with time-resolved powder diffraction (tr-XRD). In contrast to commonly used methods like Differential Scanning Calorimetry, tr-XRD can provide information about the polymorphs as well. Since synchrotron radiation is too expensive for exhaustive time-resolved experiments, a special designed tr-XRD equipment has been used to study the phase behavior of cocoa butter and milk fat, bringing more insight in phenomena like the memory effect.

P05.04.018 DEATH BY LETHAL INJECTION: STRUCTURE OF A NOVEL PHOSPHOTYROSINE BINDING DOMAIN. Craig L. Smith, James B. Bliska*, and Mark A. Saper, Biophysics Research Division and Department of Biological Chemistry, University of Michigan, Ann Arbor MI 48109, *Department of Molecular Genetics and Microbiology, SUNY Stony Brook, Stony Brook, NY 11794

YopH is a modular protein that is secreted and translocated into host macrophages by the contact dependent type III "injectosome" of the Yersinia sp.. YopH inibits phagocytosis supressing primary host defenses through dephosphorylation of host proteins p130Cas, paxillin, and focal adhesion kinase (FAK) by its C-terminal tyrosine phosphatase domain. Motifs responsible for the secretion and translocation of YopH are located in the first 71 residues of the N-terminal domain. This domain also binds to p130Cas and paxillin in a phosphotyrosine dependent manner. Although N-terminal domain of YopH binds phosphotyrosine peptides like SH2 and PTB domains, it lacks significant homology to these domains and may represent a novel protein-protein interaction module.

Our lab previously solved the crystal structure of the catalytic domain (163-468) to 2.5 Å resolution. We have now crystallized and solved the structure of the N-terminal domain of YopH (1-130) to 2.2 Å resolution. The protein crystallizes in the orthorhombic space group C2221 with unit cell parameters a=47.9 Å, b=120.7 Å, c=48.8 Å. A 2.8 Å MIR map using phases from three heavy atom derivatives (FOM=0.49 to 2.2 Å) produced high quality electron density allowing for tracing of over 80% main chain and 70% of the sidechain. After several cycles of refinement and phase combination, we currently have a model that includes 125 of the 130 residues with an R_{work}=0.29 and an R_{free}=0.37. The fold is unlike that of other phosphotyrosine binding proteins such as SH2 and PTB. Further refinement and co-crystallization with phosphotyrosine peptides is in progress.

M05.OF.005 FORMATION OF REGULAR SUBMICRON SURFACE PATTERN BY MEANS OF BLOCK COPOLYMERS. Martin Möller, Laboratory of Organic and Macromolecular Chemistry, University of Ulm, Germany.

Highly branched polymer structures, like dendrimers, cylindrical polymer brushes, and block copolymer micelles do not interpenetrate each other in concentrated solution or the melt to the same extent as linear macromolecules. While the latter form random coil conformations which can overlap with each other and interact via many molecular segments, highly branched or brush type structures interact via a more or less well defined molecular surface. This inability to undergo extensive interpenetration has also the consequence that dissolved, i.e., solvent swollen molecules undergo a collapse to form compact particles upon decreasing solvent quality or upon drying a solution. A simple, nevertheless intriguing consequence of the particulate character of highly branched polymer structures is the ability to form spontaneously very well defined monofilms if a solution is cast on a flat substrate. Long range lateral interactions in connection with capillary forces enforce the formation of a closed film, similarly like it is observed in the film formation of latices.

In the case blockcopolymer micelles such a formation of regular monofilms can be used to prepare quasi regular arrays of nanometer sized metal and metal oxide clusters on flat substrates. In the first place polymers micelles with a polar core were generated by dissolution of poly(styrene)-block-poly(2-vinylpyridine) and poly(styrene)-block-poly(ethyleneoxide) in toluene. These micelles were used as nanocompartments which were loaded with a defined amount of a metal salt. Then a suitable substrate was coated by a monolayer of the micelles. Exposure to an oxygen plasma allowed to remove the polymer completely leaving back the naked metal particles firmly attached to the substrate in the same quasi-hexagonal order as in the film. The height of the clusters could be varied between 1 nm and 15 nm depending on the concentration of the metal salt. The interparticle distance could be varied between 30 nm and 170 nm. Such lattices of Au particles have been used to bind other molecules like streptavidine proteines in an ordered array and for patterned SAMs. The approach has been extended to other noble metals but also to magnetic Co and Ni particles, in the latter case by by using a reductive plasma.

M09.OA.001 STRUCTURES OF THE N-TERMINAL AND HEXAMERIZATION DOMAINS OF N-ETHYLMALEIMIDE-SENSITIVE FUSION PROTEIN. W.I. Weis, A.P. May, K.M.S. Misura, C.U. Lenzen, S.W. Whiteheart*, Dept. of Structural Biology, Stanford University School of Medicine, Stanford, CA 94305 USA and *Dept. of Biochemistry, Chandler Medical Center, University of Kentucky College of Medicine, Lexington, KY 40536 USA

The cytosolic ATPase NSF disassembles complexes of membrane-bound proteins known as SNAREs, an activity essential for vesicular trafficking. The amino-terminal domain of NSF (NSF-N) is required for the interaction of NSF with the SNARE complex through the adaptor protein α-SNAP. NSF-N is followed by two homologous ATP-binding cassettes, designated D1 and D2, that possess essential ATPase and hexamerization activities, respectively. The crystal structures of NSF-N and D2 and their implications for NSF mechanism will be described.

P07.07.027 (N, N -DIMETHYLPIPERIDINIUM)$_4$ CU_5CL_{14}: A RARE EXAMPLE OF AN IRREGULAR CU(II) CHLORIDE CHAIN STRUCTURE. Allison Talley and Marcus R.Bond, Department of Chemistry, Southeast Missouri State University, Cape Girardeau, MO 63701; Carl J. Carrano, Department of Chemistry, Southeast Missouri State University, San Marcos, TX 78666.

This compound is the third known example of a rare class of $A_{n-1}Cu_nCl_{3n-1}$ compounds that are found only for a narrow range of A cation size. These compounds contain irregular, linear copper(II) chloride chains where tri(μ-chloro) bridging occurs between copper (II) ions within a pentanuclear oligomeric repeat unit and these repeat units are linked together by di(μ-chloro) bridges. The coordination geometries of the Cu(II) ions within the oligomeric unit differ dramatically, ranging from elongated octahedral to distorted square pyramidal. The title compound contains the largest known A cation in this class, yet still crystallizes with a chain structure similar to that found for the smallest A cation The oligomeric unit is, however, noticeably stretched as a result of including the larger cation. The title compound crystallizes in a crystal class (triclinic) that differs from both examples known already (monoclinic and orthorhombic). This provides a range of structural data that enables us to make the first attempt at describing the crystal chemistry of these unusual compounds.

Crystal data: triclinic P $\overline{1}$, a = 9.066(2) Å, b = 11.859(3) Å, c =13.046(4) Å, α = 87.22(3)° β = 71.81(3)°, γ = 67.62(2)° V =1228.3(5)Å^3, *Z* = 1, 3433 reflections collected (2505 unique, observed), least-squares refinement of 260 parameters to *R* = 0.0408 and *wR* =0.0556.

P05.04.008 CRYSTAL STRUCTURE OF THE INTEGRIN α2β1 INSERTED DOMAIN IN COMPLEX WITH A COLLAGEN LIKE PEPTIDE. [*]J. Emsley, [¥]C.G. Knight, [¥]R.W. Farndale, [¥]M.J. Barnes, [*]R.C. Liddington, [*]Department Of Biochemistry, Leicester University, Leicester, Le17rh, [¥]Department Of Biochemistry, Cambridge University, Tennis Court Road, Cambridge Cb2 2pt.

Integrin α2β1 is a collagen receptor that plays an essential role in the adhesion of platelets during primary haemostasis. α2β1 binding to collagen is magnesium dependant and is mediated through the 200 residue inserted 'I' domain of the alpha subunit (α2-I). The triple-helical structure of collagen is required for α2-I domain recognition and several groups have reported similar binding affinities in the range 50-500 nanomolar. We have previously reported the crystal structure of the α2-I domain determined to high resolution [1]. The α2-I domain structure adopts the dinucleotide binding fold, and contains a metal ion dependent adhesion site (MIDAS) motif with bound Mg^{2+} at the top of the beta-sheet. This structure revealed a new helix (the C-helix) protruding from the MIDAS site face which creates a groove centred on the magnesium ion. Recently the specific collagen sequences recognised by the a2-I domain have been identified as a 6 residue segment GFPGER (P=hyroxyproline) using overlapping synthetic peptides derived from a bovine collagen type I fragment. The ER residues of this segment have been shown to play an essential role in binding. By mixing together the collagen like peptide and the integrin α2-I domain in the presence of a divalent cation small crystals of the complex could be grown from sitting drop crystallisation experiments. The structure was solved to 2.5Å resolution and revealed the collagen triple helix bound at the MIDAS site with a glutamate sidechain from the GER motif coordinating to the metal ion on the I domain.

[1] Emsley, J., King, S.L., Bergelson, J.M., Liddington, R.C. *J. Biol. Chem.* (1997) **272**, 28512-28517.

P06.04.077 HIGH RESOLUTION CRYSTAL STRUCTURE OF THE DNA-BINDING DOMAIN OF MOUSE C-MYB. T.H. Tahirov, M. Sasaki [1,2], K. Sato [1,3], H. Morii, S. Ishii [4], S. Adachi [5], K. Ogata [1,2], [1] Kanagawa Academy of Science and Technology, [2] Department of Structural Biology, [3] Department of Biochemistry, Yokohama City University School of Medicine, 3-9 Fukuura, Kanazawa-ku, Yokohama 236-0004, Japan, [4] Protein Folding Group, National Institute of Bioscience and Human Technology, 1-1 Higashi, Tsukuba, Ibaraki 305-0074, Japan [5] RIKEN Harima Institute, 323-3, Mihara, Mikazuki, Sayo, Hyogo 679-5143, Japan

c-Myb is a transcription regulatory protein. It contains three functional domains responsible for DNA binding (homologous repeats R1, R2 and R3), transcriptional activation, and negative regulation of DNA binding. The Myb DNA-binding domain is highly conserved and involved in recognition of regulatory proteins such as C/EBP family members and Cyp-40. Thin needle like crystals of R2R3, a minimal DNA-binding fragment, were obtained by vapour diffusion method. Transformation of crystals to low-humidity form allowed high resolution data collection at BL44B2. Structure was solved by molecular replacement method and refined at 1.6 Å resolution. Overall fold of the core of each repeat is similar to "myb fold" determined by NMR, however, the relative orientation of repeats and the structure of the linker region in free state are different compare to DNA-bound state. A sodium/potassium binding site was found in each repeat and one of them mediates the interaction between the R2 and R3 repeats. Surface properties and possible interaction sites of R2R3 fragment will be discussed in detail.

P05.24.008 CHARACTERISATION OF MANGANESE OXIDES OBTAINED BY SOL-GEL TECHNOLOGY. C. Vázquez Vázquez & M.A. López Quintela Facultade de Química. Departamento de Química Física Universidade de Santiago de Compostela. Avenida das Ciencias, s/n E-15706 Santiago de Compostela (Spain)

We have synthesized nanoparticles of manganese oxides by the sol-gel method. Urea was used as gelificant agent because of the slow decomposition of urea in hot aqueous solutions, releasing hydroxide ions. The gel was decomposed at 250 ºC and the resulting powders were calcined at temperatures up to 1000 ºC. The nanoparticles were structurally characterized by X-ray diffraction and the Rietveld method was used in order to extract structural and microstructural parameters.

At low temperatures, the main phases are Mn_5O_8 and bixbyite-O, α-Mn_2O_3 (orthorhombic). Increasing temperature, above 400 ºC, bixbyite-O remains as unique stable phase. At 900 ºC it is observed the starting transformation between bixbyite-O to haussmanite, Mn_3O_4. Crystallite size of bixbyite-O ranges from 22 to 70 nm as calcination temperature increases.

The above phase transitions are well observed by thermogravimetry: the transformation of bixbyite-O to haussmanite is complete due to the flowing nitrogen atmosphere, free of oxygen.

P08.09.002 ANALYSIS OF QUALITATIVE CATIONIC COMPOSITION OF SILICATES. O.E.Gorchakova and N.L.Smirnova, Department of Chemistry, All-Russian Inst. of Scientific and Technical Information, Moscow, Russia.

A mineral systematics variant based on qualitative *sfdp*-formulae is suggested, where *s* is alkali and earth-alkali elements including H (14 elements); *f*-lanthanoids and actinides (28); there are 30 *d*-elements from Sc to Hg and 30 *p*-elements from B to Rn. Only ideal qualitative formulae consisting of main (species forming) elements without isomorphic admixtures, coefficients and atomic charges are considered. Silicates containing one cation are considered, these are 294 mineral species and, consequently, 294 cationic formulae. A mineral species corresponds to every cation, so the cationic composition systematics represent that of mineral species. It was found 193 (66%) *s*-cations, 6 (2%) *f*-cations, 72 (24%) *d*-cations and 23 (8%) *p*-cations among 294 cations. Eight (57%) of 14 *s*-elements are present in ordinary silicates: Li (1,1%), Be (1,1%), Na (23,3%), Mg (28%), K (8,2%), Ca (33,2%) Sr (1,1%), Ba (4,0%). Ca, Mg, Na (84,5%) are leaders among *s*-cations. Elements *f* are represented only by 5 (18%) of 28: Ce (16,7%), Yb (16,7%), Th (33,2%), U (16,7%), TR (16,7%). Only 9 (32%) of *d*- elements were found in the ordinary silicates: Sc (1,4%), Mn (23,6%), Fe(43,0%), Ni(12,5%), Cu(2,8%), Zn(9,7%), Y(4,3%),Hf(1,4%). Leaders are Fe, Mn (66,6%) among *d*-cations. The silicates considered contain only 4 (13%) of 30 *p*-elements: N (13%), Al (74%), Pb (8,7%), Bi (4,3%). Al (74%) is a leader among *p*-elements. There are 26 various cations in the ordinary silicates and only 4 (15,5%) are leaders: Ca, Mg, Na, Fe. Mean frequency of K, Mn, Al (11,5%) is the same as of Ba, Zn, Ni (11,5%), and it is low for the rest 16 (61,5%) cations. The frequency for these four groups of cations is different if to consider all 294 mineral species. Leaders are Ca, Mg, Na, Fe (66%), cations K, Mn, Al (17%) have a middle frequency, Ba, Zn, Ni (8,2%) are met rarely; the rest 16 cations will be the rarest ones (8,8%). Thus, study of silicates with one cation revealed a sharp preference of these minerals to 4 cation-leaders: Ca, Mg, Na, Fe. Analysis of the qualitative composition of minerals can be an important characteristic for an economic geology prognosis.

P06.06.019 X-RAY DIFFRACTION STUDIES OF PHASE TRANSITIONS IN OLEIC ACID. P. Tandon, R. Neubert [1], G. Föster [2], S. Wartewig [3], [1] Department of Pharmacy, Martin-Luther-Universität Halle-Wittenberg, D-06120 Halle(Saale), Germany, [2] Department of Chemistry, Martin-Luther-Universität Halle-Wittenberg, D-06099 Halle(Saale), Germany, [3] Institute of Applied Dermatopharmacy, Martin-Luther-Universität Halle-Wittenberg, D-06120 Halle(Saale), Germany

Oleic acid (OA) is an unsaturated lipid and plays an important role in many biological systems. The solid-solid gamma to alpha transition has been investigated using X-ray diffraction, FT-Raman spectroscopy and DSC. The X-ray diffraction and the molecular simulation studies using CERIUS2 program indicate that the gamma phase of OA crystallized from melt has a monoclinic unit cell with beta = 91° and the other unit cell parameters are the same as given by Abrahamsson and Ryderstedt-Nahringbauer [1]. Both X-ray diffraction and FT-Raman studies indicate that the conformation of the olefin group changes due to the gamma to alpha transition. In the alpha phase, the olefin group is in the skew-cis-trans conformation. This change in the conformation of the olefin group results in a changed orientation of the methyl-sided chains, whereas the orientation of the carboxyl-sided chains remains the same. In the gamma phase, the methylene chains at both sides of the C=C group form the O'parallel subcell. Simulation studies demonstrate that during the gamma to alpha transition only the subcell of methyl-sided chains transforms to the O perpendicular one, while the carboxyl-terminal chains keep the O'parallel subcell. The unit cell parameter for these two phases are not very different, only the cross sectional area of the unit cell and the long spacing show an ordinary thermal expansion caused by the gamma to alpha transition. The FT-Raman studies indicate that the number of gauche conformers in the methyl-terminal alkyl chains drastically increases in the course of the gamma to alpha transition, but the end of the methyl-sided chain remains mostly in the ordered tt conformation in the alpha phase, too. However, the carboxyl-sided alkyl chains exist in the ordered conformation in both the alpha and gamma phases. Financial assistance to P.T. from the Alexander von Humboldt Foundation is gratefully acknowledged.

P07.07.99 CYANO-BRIDGED BIMETALLIC COMPLEXES WITH NITROPRUSSIDE OR HEXACYANO-FERRATE(II). Z. Smékal and Z. Trávníček, Dept. of Inorganic and Physical Chemistry, Palacký University, 771 47 Olomouc, CZ, and J. Marek, X-Ray Laboratory of Dept. Inorg. Chemistry & Laboratory of Biomolecular Strukture and Dynamics, Masaryk University, 611 37 Brno, CZ.

We are concerned in the synthesis and physico-chemical study of μ-cyano copper(II) and nickel(II) complexes [1]. The complexes of composition $[Cu(1,2\text{-pn})_2Fe(CN)_5NO].H_2O$ (1,2-pn = 1,2-diaminopropane), $[Cu(L)Fe(CN)_5NO].xH_2O$ (L = N,N,N',N'-tetramethyl-ethylenediamine, x = 0.5; L = N,N,N'-trimethylethylenediamine, x = 1; L = diethylenetriamine, x = 0; L = 3,3'-diamino-N-methyl-dipropylamine, x = 2) and $[Cu(ept)]_3[Fe(CN)_6](ClO_4)_2.5H_2O$ (ept = N-(2-aminoethyl)-1,3-diamino-propane) have been prepared. The structures of $[Cu(1,2\text{-pn})_2Fe(CN)_5NO].H_2O$ (Fig. 1) and $[Cu(ept)]_3[Fe(CN)_6](ClO_4)_2.6H_2O$ (Fig. 2) were determined by single crystal X-ray analysis. The compound (1) is binuclear with one bridged cyano group between copper and iron atoms. Polymeric complex (2) exhibits 2D sheet structure (all cyano groups form bridges).
