## HIGHLIGHTS

- New noncentrosymmetric trigonal double borate  $\text{Rb}_3\text{EuB}_6\text{O}_{12}$  is synthesized and the structure is obtained by Rietveld analysis.
- The structure features a three-dimensional framework composed of the  $[\text{B}_5\text{O}_{10}]^{5-}$  groups bridged by Eu-O polyhedra.
- The second harmonic generation effect of  $\text{Rb}_3\text{EuB}_6\text{O}_{12}$  is 16 times higher than that of the  $\alpha$ -quartz.
- The photoluminescence emission spectrum is dominated by a narrow line from the hypersensitive  $^5\text{D}_0 - ^7\text{F}_2$  manifold of  $\text{Eu}^{3+}$ .

Solid state reaction

## ABSTRACT

New noncentrosymmetric double borate  $\text{Rb}_3\text{EuB}_6\text{O}_{12}$  was designed and synthesized by the solid state reaction method, and its crystallographic parameters were obtained by Rietveld analysis. This borate crystallizes in the trigonal space group  $R\bar{3}2$  with cell parameters  $a = 13.4604(2)$  Å,  $c = 30.7981(5)$  Å,  $Z = 15$ . Its structure features a three-dimensional framework composed of the  $[\text{B}_5\text{O}_{10}]^{5-}$  groups that are bridged by Eu-O polyhedra. The existence of  $\text{B}_5\text{O}_{10}$  group in the structure was confirmed by vibrational spectroscopy.  $\text{Rb}_3\text{EuB}_6\text{O}_{12}$  melts incongruently at 1101 K. The second harmonic generation effect of  $\text{Rb}_3\text{EuB}_6\text{O}_{12}$  is 16 times higher than that of the  $\alpha$ -quartz standard. In the luminescence spectrum, the domination of a single prominent narrow line from the hypersensitive  $^5\text{D}_0 - ^7\text{F}_2$  manifold of  $\text{Eu}^{3+}$  ions is observed, while the  $^5\text{D}_0 - ^7\text{F}_1$  manifold and ultranarrow  $^5\text{D}_0 - ^7\text{F}_0$  line are of

## 1. Introduction

During the last decades, borate crystals were extensively studied mainly in connection with the valuable properties of several nonlinear optical (NLO) borate crystals discovered in the past. Among the most attractive features of borate crystals are such key characteristics as their transparency in a deep ultraviolet (UV) range, high optical damage threshold combined with appropriate nonlinearity, and suitable chemical stability of optical surface should be pointed; they define wide applications of borate materials in modern laser optics and nanophotonics [1–11]. Within borate matrices, boron ions can be either three- or four-fold coordinated, and the combination of BO<sub>4</sub> and BO<sub>3</sub> units produces a large variety of crystal structures with different properties [12–15]. In recent years, many complex borate crystals were discovered and evaluated in searching for new efficient polyfunctional materials for nonlinear optics and photonics [16–23].

One of the extensively studied trends concerning borate crystals is doping them with rare earth ions producing either phosphors or lasing crystals with the possibility of simultaneous frequency doubling of generated radiation within the same crystal. Such noncentrosymmetric (NCS) borates as YAl<sub>3</sub>(BO<sub>3</sub>)<sub>4</sub> [24] Ca<sub>4</sub>RO(BO<sub>3</sub>)<sub>3</sub> (R = rare earth of Y) [25] and Na<sub>3</sub>La<sub>9</sub>O<sub>3</sub>(BO<sub>3</sub>)<sub>8</sub> [26] are known as self-frequency doubling materials, when doped with Nd. YAl<sub>3</sub>(BO<sub>3</sub>)<sub>3</sub> doped with Mn<sup>4+</sup> or pair Yb<sup>3+</sup>/Tm<sup>3+</sup>, is prospective as an efficient phosphor material [27,28]. Femtosecond pulse generation was carried out in the Ca<sub>3</sub>Gd<sub>2</sub>(BO<sub>3</sub>)<sub>4</sub>:Nd<sup>3+</sup> crystal [29]. However, within M<sub>2</sub>O–RE<sub>2</sub>O<sub>3</sub>–B<sub>2</sub>O<sub>3</sub> (M = alkali metal, RE = rare earth) systems, only several NCS crystalline media have been found up to date: namely, Na<sub>3</sub>La<sub>2</sub>(BO<sub>3</sub>)<sub>3</sub> [30], Rb<sub>3</sub>Y<sub>2</sub>B<sub>3</sub>O<sub>9</sub> [31] Na<sub>3</sub>La<sub>9</sub>O<sub>3</sub>(BO<sub>3</sub>)<sub>8</sub> [32], K<sub>3</sub>REB<sub>6</sub>O<sub>12</sub> (RE = Y, Eu, Tb, Lu) [33–36] and Rb<sub>3</sub>NdB<sub>6</sub>O<sub>12</sub> [37]. It is worth noting that K<sub>3</sub>REB<sub>6</sub>O<sub>12</sub> (RE = Y, Eu, Tb, Lu) and Rb<sub>3</sub>NdB<sub>6</sub>O<sub>12</sub> are related to the same structure type, and they crystallize in trigonal space group R32 and exhibit a noticeable SHG signal. The UV cut-off edge of K<sub>3</sub>YB<sub>6</sub>O<sub>12</sub> and Rb<sub>3</sub>NdB<sub>6</sub>O<sub>12</sub> is reported to be at 195–197 nm [33,37]. These findings indicate that the M<sub>2</sub>O–RE<sub>2</sub>O<sub>3</sub>–B<sub>2</sub>O<sub>3</sub> ternary systems are complex enough, and other NCS borate crystals, transparent in UV range, can be formed. In the present study, we employ larger alkali ions since they could have a stronger polarizability and, hence, a stronger overall nonlinear optical (NLO) response can be expected. The structural and optical properties of Rb<sub>3</sub>Y<sub>2</sub>B<sub>3</sub>O<sub>9</sub> have not being investigated up to date. Recently, we reported on the properties of the new NCS borate crystal, Rb<sub>3</sub>NdB<sub>6</sub>O<sub>12</sub> [37], which is featured by an unusual blue shift of luminescent lines with

respect to traditional laser materials. This shift is larger than that in other borate family: namely, huntites, and it is close to that observed in fluorides. The observed peculiarity must be ascribed to a specific influence of the current boron-based framework structure. Respectively, it is interesting to examine the properties of other rare earth ions in the same structure. In the present study, the synthesis of new crystal Rb<sub>3</sub>EuB<sub>6</sub>O<sub>12</sub> is performed. Its structural and vibrational characteristics are investigated, and the luminescent properties of Eu<sup>3+</sup> ion are studied in this new borate structure.

## 2. Experimental

The samples were prepared by solid state reactions using high-purity starting reagents (Red Chemist, Ltd., Russia): Rb<sub>2</sub>CO<sub>3</sub> (99.9%), RE<sub>2</sub>O<sub>3</sub> (RE = Eu) (99.99%), and H<sub>3</sub>BO<sub>3</sub> (99.99%). Before weighing, Rb<sub>2</sub>CO<sub>3</sub> was preheated at 900 °C for 24 h to remove any absorbed water. The reagents were weighed on an analytical balance at the accuracy of 0.5 mg. The mixtures of Rb<sub>2</sub>CO<sub>3</sub>, RE<sub>2</sub>O<sub>3</sub>, and H<sub>3</sub>BO<sub>3</sub> in stoichiometric proportions were thoroughly ground in an agate mortar, slowly heated in a muffle furnace to 500 °C at the rate of 1 °C/min and held at this temperature for 24 h. Then, the samples were reground and annealed at 700–750 °C for 24–72 h until reaching equilibrium. Temperatures were measured with a Pt–PtRh thermocouple. The temperature was controlled to be within ± 2 °C up to 1200 °C with an OMRON controller. The equilibrium was specified when two successive heat treatments resulted in the identical X-ray patterns.

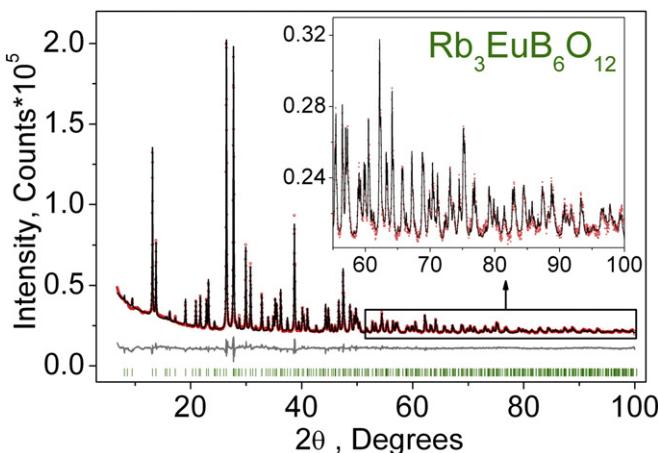

The powder X-ray diffraction (XRD) data were recorded by a D8 ADVANCE Bruker AXS diffractometer (Vantec-1 detector) at room temperature using the CuK<sub>α</sub> radiation and scanning over the range of 2θ = 8–100°. The step size of 2θ was 0.021° and the counting time was 10 s per step. The Rietveld refinement was implemented using TOPAS 4.2 [38]. Almost all peaks were indexed by a trigonal cell (space group R32) with the parameters close to those of K<sub>3</sub>YB<sub>6</sub>O<sub>12</sub> [33].

**Fig. 1.** Measured (red), calculated (black) and differential (blue) diffraction patterns of  $\text{Rb}_3\text{EuB}_6\text{O}_{12}$ .

Differential scanning calorimetric (DSC) measurements were performed on a STA 449 F1 Jupiter thermoanalyzer (NETZSCH) over the temperature range of 30–900 °C in an argon flow. Pt crucibles were used as vessels. Pt–PtRh thermocouples were used for the measurement. The temperature measurement precision was  $\pm 1$  °C. The heating and cooling rates were 10 °C/min. The second harmonic generation (SHG) response of powder samples was measured with a Q-switched YAG:Nd laser at  $\lambda_{\text{o}} = 1064$  nm in the reflection mode. The SHG signal intensities ( $I_{2\omega}$ ) from the sample and from the reference sample (polycrystalline  $\alpha$ - $\text{SiO}_2$ ) were registered comparatively. The crystal micro-morphology was observed by second electron microscopy (SEM) using a LEO 1430 device. The measurements were performed using the instrumental equipment of CCU “Nanostructures”. The infrared spectra were carried out to specify the boron coordination in the new compound. The mid-infrared spectra were obtained at room temperature using a Nicolet-380 infrared spectrophotometer with KBr pellets as standards. The spectra were obtained in the range from 500 to 2000  $\text{cm}^{-1}$  with the resolution of 1  $\text{cm}^{-1}$ . The unpolarized Raman spectra were collected in a backscattering geometry using a triple monochromator Horiba Jobin Yvon T64000 Raman spectrometer operating

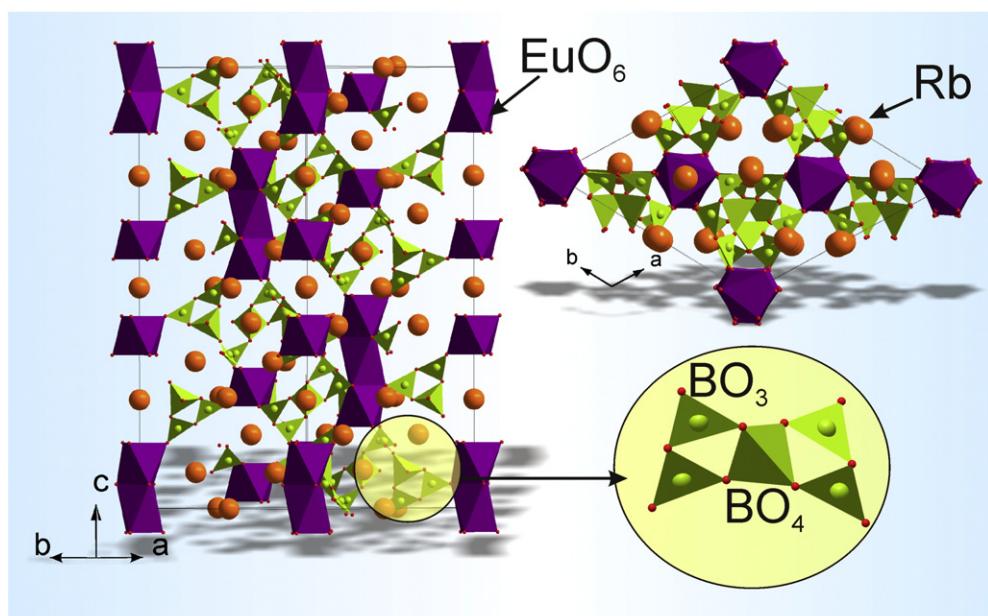

in the subtractive mode then detected by an LN-cooled charge-coupled device. The spectral resolution for the recorded Stokes side Raman spectra was set to  $\sim 2 \text{ cm}^{-1}$  (this resolution was reached by using gratings with 1800 grooves/mm and 100  $\mu\text{m}$  slits).

### 3. Results and discussions

The synthesized product was a free-flowing powder. Examination of the XRD pattern of the synthesized compound revealed its close similarity to that of  $\text{K}_3\text{YB}_6\text{O}_{12}$ . Therefore, the initial structure model and atomic positions of  $\text{K}_3\text{YB}_6\text{O}_{12}$  were adopted for the structure refinement.  $\text{Rb}_3\text{EuB}_6\text{O}_{12}$  crystallizes in noncentrosymmetric space group R32, as it was supported by SHG measurements. The intensity of the green light ( $\lambda = 532$  nm) produced by  $\text{Rb}_3\text{EuB}_6\text{O}_{12}$  is about 16 of that produced by the  $\alpha$ -quartz standard. The intensity of SHG effect is similar to that of  $\text{K}_3\text{YB}_6\text{O}_{12}$  [33]. The weak SHG effect of  $\text{Rb}_3\text{EuB}_6\text{O}_{12}$  and  $\text{K}_3\text{YB}_6\text{O}_{12}$  is due to the  $\text{B}_5\text{O}_{10}$  groups which are aligned in the almost opposite directions and, consequently, contribute little to the SHG effect.

The refinement results and atomic coordinates obtained for  $\text{Rb}_3\text{EuB}_6\text{O}_{12}$  are summarized in Tables 1, 2 and the final Rietveld profiles are shown in Fig. 1. The  $\text{Rb}_3\text{EuB}_6\text{O}_{12}$  structure contain a three-dimensional framework composed of  $[\text{B}_5\text{O}_{10}]^{5-}$  groups bridged by Eu-O polyhedra (Fig. 2). The  $[\text{B}_5\text{O}_{10}]^{5-}$  group consists of one  $\text{BO}_4$  tetrahedron and four  $\text{BO}_3$  triangles that form double B—O rings via the common tetrahedron (Fig. 2). Each  $[\text{B}_5\text{O}_{10}]^{5-}$  group is linked to four different Eu-O polyhedra and, likewise, each Eu-O polyhedra is connected to four neighboring  $[\text{B}_5\text{O}_{10}]^{5-}$  groups. The Eu-O polyhedra are formed by the face-sharing linked  $\text{EuO}_6$  octahedra. Rubidium cations are located in large cavities of the framework structure (Fig. 2). The main bond lengths obtained for  $\text{Rb}_3\text{EuB}_6\text{O}_{12}$  are listed in Table 1S, and one can see a good agreement of refined values with those reported for the structures containing similar  $[\text{B}_5\text{O}_{10}]^{5-}$  units [12].

The unit cell volume dependence on the element combination in  $\text{M}_3\text{REB}_6\text{O}_{12}$  ( $\text{M}$  = alkaline metals; RE = Y, rare earth metals) crystal family is shown in Fig. 3 [33–37,39]. It should be noted that all compounds, besides  $\text{K}_3\text{TbB}_6\text{O}_{12}$ , have space group R32 and similar cell parameters. The  $\text{K}_3(\text{Tb}, \text{Lu}, \text{Eu})\text{B}_6\text{O}_{12}$  compounds have space group R3<sub>2</sub> which is non-standard and, moreover, cell parameter  $c$  is two times smaller in comparison with other compounds [34–36]. The small cell volume of  $\text{K}_3(\text{Tb}, \text{Lu}, \text{Eu})\text{B}_6\text{O}_{12}$  leads to (Tb, Lu, Eu)/K disordering which seems to be not reasonable. As it appears, these structures should

**Fig. 2.**  $\text{Rb}_3\text{EuB}_6\text{O}_{12}$  crystal structure.

be reinvestigated in the future in order to understand the difference. For the analysis shown in Fig. 3, the *c* parameters and unit cell volumes reported for  $K_3(Tb, Lu, Eu)B_6O_{12}$  were doubled to uniform the space group *R*32 for  $M_3REB_6O_{12}$  crystals. Then, as it is seen from Fig. 3, the cell volume increases with the IR(M) and IR(RE) increase and the curves for Rb and K are practically parallel. In the first approximation, we can write  $V = A \times IR(RE) + B \times IR(M) + C$ , where *A*, *B*, *C* are some constants. The least-square method was used to estimate *A*, *B*, *C* using the known data about the cell volumes of all known compounds and ions radii of constituted elements [33–37,39]. It was found that general formula  $V = 2222.0 \times IR(RE) + 1212.6 \times IR(M) + 904.7 \text{ \AA}^3$  very well fits the cell volumes of all known compounds, including  $Rb_3EuB_6O_{12}$  (Fig. 3). It is interesting that  $A = 2222.0$  is almost two times bigger than  $B = 1212.6$ , and this means that the cell volume variation is dominated by changing IR(RE). Moreover, a similar analysis for the cell parameter variation reveals relations  $a = 1.12617 \times IR(RE) + 1.51834 \times IR(M) + 10.10377 \text{ \AA}$  and  $c = 9.05935 \times IR(RE) + 0.91584 \times IR(M) + 20.86787 \text{ \AA}$ . The equation for cell parameter *c* showed that the M cation is of low influence on the *c* parameter value, but RE provides a ten times bigger effect. In the  $M_3REB_6O_{12}$  structure, this effect can be associated with the column of three  $(RE)_6O_6$  octahedra linked by faces, which goes along the *c*-axis. Probably, increasing RE ion radii cannot be compensated by other ion moving and this leads to a strong *c*-axis stretching.

Using the diagram shown in Fig. 3, some predictions are possible for the discovery of new NCS borates with the  $K_3YB_6O_{12}$  structure. The existence of compounds ( $RE = Yb, Tm, Er, Ho, Dy, Gd$ ) and  $Rb_3REB_6O_{12}$  ( $RE = Pm, Sm$ ) seems to be evident. Besides, the formation of solid solutions  $(K, Rb)_3REB_6O_{12}$  may be reasonably supposed for many RE. The situation with  $M = Na, Cs$  is less clear. However, the existence of solid solutions  $(Na, Rb)_3REB_6O_{12}$  with averaged IR(Na,Rb) close to that of IR(K) is expected at a high probability. Above this, the existence of solid solutions  $(Na, K)_3REB_6O_{12}$  with a partial substitution of Na for K cannot be excluded at Na/K ratios when the impact of averaged IR(Na,K) on the structural parameters is not strong.

The synthesized  $Rb_3EuB_6O_{12}$  powder possesses light-cream tint, as evident in Fig. 4, that is a common characteristic of Eu-containing oxides [40–42]. A typical SEM image of the particle is shown in Fig. 5. Under the selected technological conditions, the synthesis resulted in the agglomerates of 5–20  $\mu\text{m}$  in size formed by strongly coalescent individual grains with a diameter lower than 1  $\mu\text{m}$ . This micromorphology is common in oxides when the temperature/time conditions used for the solid state reaction are high enough for the active grain interdiffusion [16,34,37,43,44]. It should be pointed out that the  $Rb_3EuB_6O_{12}$  particles possessed a strong charging effect during SEM measurements and this

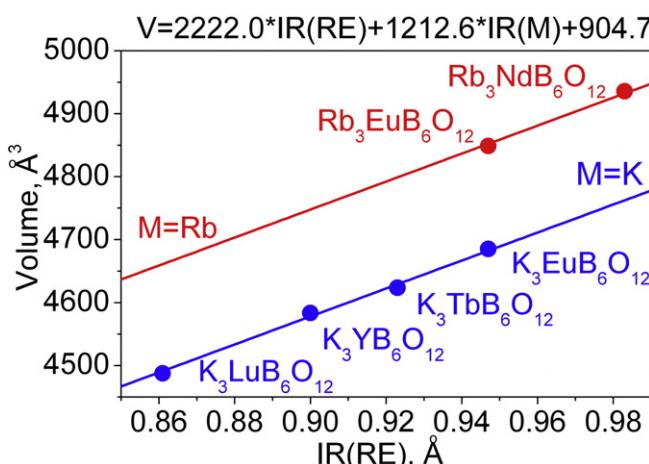

Fig. 3. The dependence of unit cell volume *V* on the element combination in  $M_3REB_6O_{12}$  (*M* = alkaline metals; RE = Y, rare earth metals) crystal family.

Fig. 4. The digital image of  $Rb_3EuB_6O_{12}$  powder under illumination by white light. The length of the scale bar is 7 mm.

verifies their very low conductivity common for the oxides without oxygen vacancies.

The recorded DSC curve is shown in Fig. 6. Only a sharp endothermic peak, associated with melting at 1101 K, was observed for  $Rb_3EuB_6O_{12}$ . The powder XRD pattern measured for the sample obtained by the melt solidification is shown in Fig. 1S. Among the crystalline residues, the presence of  $Rb_2(B_4O_5OH)_4(H_2O)_{3.6}$  (PDF 70–4576),  $EuBO_3$  (PDF 74–1931),  $B_2O_3$  (73–1550) was revealed [45–47]. As it is assumed, the  $Rb_2(B_4O_5OH)_4(H_2O)_{3.6}$  compound appeared due to the chemical interaction with the air during cooling because of a high hygroscopicity of the decomposition products. Besides the crystalline compounds, the amorphous component is significant. Thus, it can be concluded that  $Rb_3EuB_6O_{12}$  melts incongruently. The thermal parameters, presently available for the  $M_3REB_6O_{12}$  borates, are summarized in Table 3. Unfortunately, for  $K_3REB_6O_{12}$  compounds, the melting point was earlier measured only for  $K_3YB_6O_{12}$ . For other  $K_3REB_6O_{12}$  borates, however, the melting points can be estimated on the base of the temperature used for solid state synthesis. From the comparison of available experimental data, it can be reasonably assumed that the melting points of  $K_3REB_6O_{12}$  borates are noticeably higher than those of  $Rb_3REB_6O_{12}$  borates.

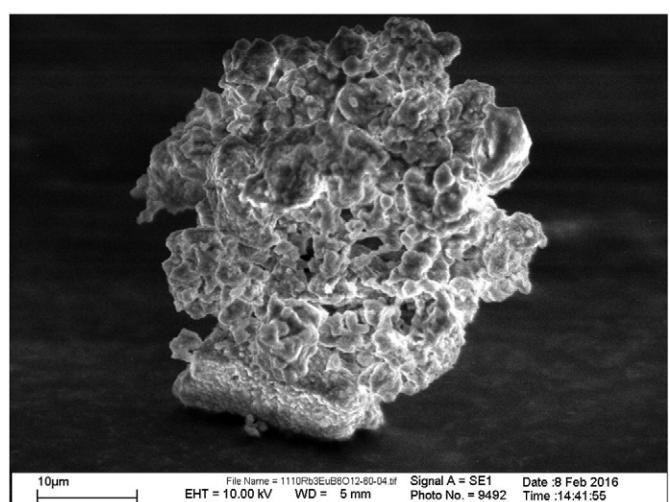

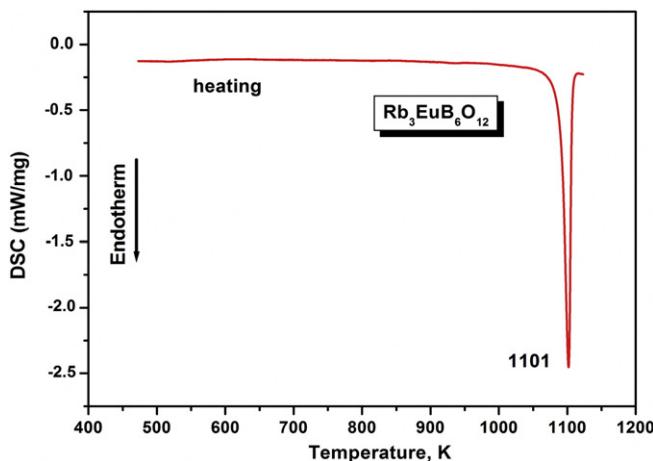

Fig. 5. SEM pattern of the  $Rb_3EuB_6O_{12}$  particle.

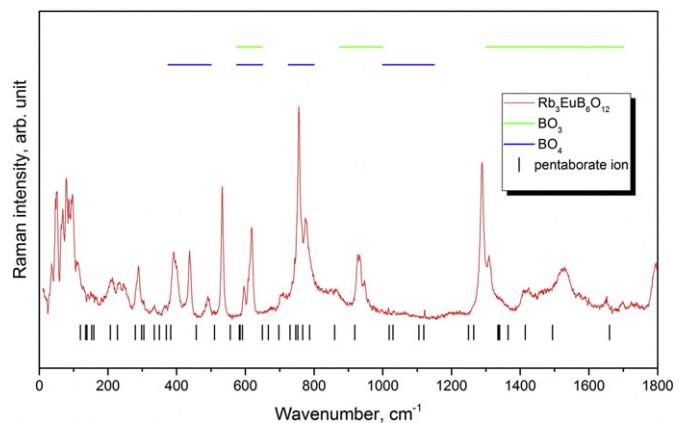

**Fig. 6.** DSC measurements in the temperature range of 298–813 K.

The Raman spectrum obtained from  $\text{Rb}_3\text{EuB}_6\text{O}_{12}$  is shown in Fig. 7. According to the XRD data, the main structural unit of  $\text{Rb}_3\text{EuB}_6\text{O}_{12}$  is the so-called pentaborate group  $[\text{B}_5\text{O}_{10}]^{5-}$  [48], which consists of one  $\text{BO}_4$  tetrahedron and four  $\text{BO}_3$  triangles (Fig. 2). The  $\nu_1$ ,  $\nu_3$ , and  $\nu_4$  normal vibration modes of planar  $\text{BO}_3$  triangles are Raman-active and  $\nu_2$ ,  $\nu_3$ , and  $\nu_4$  are infrared-active; all four normal vibrations of tetrahedral  $\text{BO}_4$  groups are Raman-active, whereas only  $\nu_3$  and  $\nu_4$  are infrared-active [49]. The total set of vibrational modes in  $\text{Rb}_3\text{EuB}_6\text{O}_{12}$  is summarized in Table 4. In Fig. 7, for comparison, the Raman frequencies of the pentaborate ion in the potassium pentaborate tetrahydrate single crystal are shown by black vertical lines [50].

The antisymmetric stretching of  $\text{BO}_3$  triangles of the pentaborate group is observed in the range of  $1300$ – $1700\text{ cm}^{-1}$  in Raman spectra (Fig. 7) and in the range of  $1100$ – $1600\text{ cm}^{-1}$  in Infrared spectra (Fig. 8). These bands' intensities are greater in Infrared than in Raman spectra [50]. This region could also be covered by the contribution from the  $\text{Eu}^{3+} \text{D}_1 \rightarrow {}^7\text{F}_2$  luminescence [41]; however, the presence of a similar band in the Raman spectrum of  $\text{Rb}_3\text{NbB}_6\text{O}_{12}$  indicates its origin both from the boron oxygen network of the  $\text{Rb}_3\text{EuB}_6\text{O}_{12}$  crystal and from the Eu luminescence. The only unexplained lines are narrow doublet at  $1290$  and  $1310\text{ cm}^{-1}$ , that is present in the Raman spectrum of  $\text{Rb}_3\text{EuB}_6\text{O}_{12}$ , but absent in  $\text{Rb}_3\text{NbB}_6\text{O}_{12}$ . Strong Raman bands for boron compounds in this region are not known. Therefore, we must ascribe it to the component of the Eu luminescence that experienced a red shift by  $100\text{ cm}^{-1}$  in the borate under study, with respect to europium molybdate. However, this suggestion needs an additional study. The symmetric stretching of  $\text{BO}_3$  triangles can be found at  $875$ – $1000\text{ cm}^{-1}$  in Raman [49,51] and at  $850$ – $975\text{ cm}^{-1}$  in Infrared spectra.

An asymmetric stretching of  $\text{BO}_4$  should be observed in Raman spectra in the range of  $1000$ – $1150\text{ cm}^{-1}$ . However, these bands' intensities are very weak [50]: in the case of Infrared spectra, these vibrations are clearly observed at  $975$ – $1100\text{ cm}^{-1}$ . The Raman bands in the region of  $725$ – $800\text{ cm}^{-1}$  are the symmetric stretching of  $\text{BO}_4$  and a strong line at  $756\text{ cm}^{-1}$  can be used as an indicator of the presence of pentaborate group [52]. The symmetric stretching of  $\text{BO}_4$ , in the range of  $750$ – $810\text{ cm}^{-1}$ , can be found in Infrared spectra. The in-plane bending of

**Fig. 7.**  $\text{Rb}_3\text{EuB}_6\text{O}_{12}$  Raman spectra in comparison with the band positions of pentaborate ion in the potassium pentaborate tetrahydrate single crystal [50].

$\text{BO}_3$  groups locate in the region of  $575$ – $650\text{ cm}^{-1}$  in Raman spectra and at  $550$ – $625\text{ cm}^{-1}$  in Infrared spectra. The out-of-plane of  $\text{BO}_3$  bending should be inactive in Raman and can be found at  $650$ – $750\text{ cm}^{-1}$  in Infrared spectra. The Raman bands in the region of  $575$ – $650\text{ cm}^{-1}$  and region of  $550$ – $625\text{ cm}^{-1}$  of Infrared spectra are related to the  $\nu_4$  bending modes of  $\text{BO}_4$ . A strong peak at  $530\text{ cm}^{-1}$  is the so-called symmetric pulse vibration of pentaborate anion [53]. The medium bands in the region of  $375$ – $500$  are  $\nu_2$  bending modes of  $\text{BO}_4$  groups.

Except for  $\text{B}_5\text{O}_{10}$  vibrations, the Raman spectrum of  $\text{Rb}_3\text{EuB}_6\text{O}_{12}$  must contain external vibrations involving the movement of heavy crystal lattice constituents (Eu and Rb). These vibrations are present in the Raman spectrum as the bands observed below  $150\text{ cm}^{-1}$ . The rotational and translational modes of  $[\text{B}_5\text{O}_{10}]^{5-}$  ion as a whole are positioned in the same frequency range, the bending modes are in the range of  $200$ – $375\text{ cm}^{-1}$ .

The luminescence spectrum of  $\text{Rb}_3\text{EuB}_6\text{O}_{12}$  excited at  $514.5\text{ nm}$  is shown in Fig. 9. The infrared part of the spectrum is multiplied by 400 to enhance the visibility of longer-wavelength Eu<sup>3+</sup> luminescent multiplets. All seven  ${}^5\text{D}_0$ – ${}^7\text{F}_j$  bands are present in this spectrum. A noticeable feature of this spectrum is the prominent ultranarrow line corresponding to the  ${}^5\text{D}_0$ – ${}^7\text{F}_0$  transition. The comparison of this line with the same line in the recently studied europium molybdate [41] is presented in Fig. 2S. The ultranarrow line position in the  $\text{Rb}_3\text{EuB}_6\text{O}_{12}$  borate is at  $579.8\text{ nm}$  and its width is  $5\text{ cm}^{-1}$  (full width at half maximum), while, in  $\alpha\text{-Eu}_2(\text{MoO}_4)_3$ , it is at  $580.4\text{ nm}$  with the width of  $2\text{ cm}^{-1}$ . As one can extract from the structural results, Eu ions occupy three inequivalent sites within the unit cell of the  $\text{Rb}_3\text{EuB}_6\text{O}_{12}$  crystal. Two of them are featured by the  $C_3$  local symmetry of Eu<sup>3+</sup> ion, while the third one possesses the  $D_3$  local symmetry. The selection rules allow the  ${}^5\text{D}_0$ – ${}^7\text{F}_0$  transition only in case of the symmetry as low as  $C_3$ , but not in the case of  $D_3$ . Therefore, the observed ultranarrow line must be ascribed to the first two sites with the required symmetry.

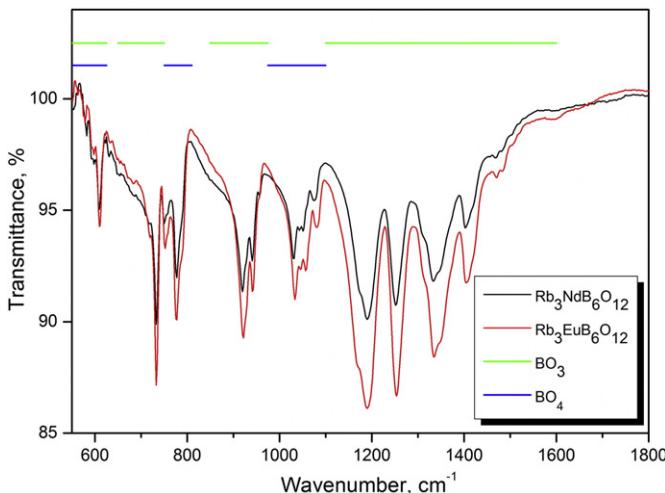

**Table 4**  
Wyckoff positions of atoms and vibrational modes in  $\text{Rb}_3\text{EuB}_6\text{O}_{12}$ .

Atom	Wyckoff position	Mechanical representation
Rb1	9e	$A_1 + 2A_2 + 3E$
Rb2	9d	$A_1 + 2A_2 + 3E$
Eu1, Eu2, Rb4	6c	$A_1 + A_2 + 2E$
Rb5	3b	$A_2 + E$
Eu3	3a	$A_2 + E$
Rb3, B1–B5, O1–O10	18f	$3A_1 + 3A_2 + 6E$ $53A_1 + 57A_2 + 110E$
Total		$A_2 + E$

Optic		$53A_1 + 109E$
Raman active modes		$56A_2 + 109E$
Infrared active modes		

**Table 3**

Thermal parameters obtained for borates with general composition  $\text{M}_3\text{REB}_6\text{O}_{12}$  ( $\text{M} = \text{K}, \text{Rb}; \text{RE} = \text{Y, rare earths}$ ).

$\text{M}_3\text{REB}_6\text{O}_{12}$	Melting temperature, K	Enthalpy, J/g	Reference
$\text{K}_3\text{EuB}_6\text{O}_{12}$	>1023	–	[34]
$\text{K}_3\text{TbB}_6\text{O}_{12}$	>1023	–	[35]
$\text{K}_3\text{YB}_6\text{O}_{12}$	1214	–	[33]
$\text{K}_3\text{LuB}_6\text{O}_{12}$	>1023	–	[36]
$\text{Rb}_3\text{NbB}_6\text{O}_{12}$	1070	–122.4	[37]
$\text{Rb}_3\text{EuB}_6\text{O}_{12}$	1101	–160.6	This work

**Fig. 8.**  $\text{Rb}_3\text{REB}_6\text{O}_{12}$  ( $\text{RE} = \text{Nd}, \text{Eu}$ ) Infrared spectra.

In most crystals and glasses containing  $\text{Eu}^{3+}$  ions, the hypersensitive  $^5\text{D}_0 - ^7\text{F}_2$  transition is typically the most intense since its oscillator strength is due to the lack of inversion symmetry, and such  $\text{Eu}^{3+}$  ion environment is rather common. This is the case of our borate, too. However, comparing the spectra of  $\text{Rb}_3\text{EuB}_6\text{O}_{12}$  and earlier studied  $\alpha\text{-Eu}_2(\text{MoO}_4)_3$ , we see that the ultranarrow line intensity, with respect to hypersensitive band, is much higher in borate than that in molybdate. To reveal the nature of this feature, we recorded the luminescence spectra of equal amounts of both materials at the same spectrometer settings in order to enable an approximate comparison of the lines intensities (difference in the Eu content and in the absorption cross sections was not accounted for). The hypersensitive band intensity is 43.7 times smaller in borate than in molybdate, while the ultranarrow line intensity is only 2.1 times smaller. Since both emissions originate from the same starting level, we can deduce that breaking the central inversion of the local environment of all three inequivalent Eu sites in  $\text{Rb}_3\text{EuB}_6\text{O}_{12}$  leads to a smaller oscillator strength gain of the hypersensitive transition than the mirror symmetry breaking in  $C_3$  sites, with respect to the same symmetry violations in a single  $C_1$  site of Eu in  $\alpha\text{-Eu}_2(\text{MoO}_4)_3$ . Comparing intensities of magnetic dipole transitions  $^5\text{D}_0 - ^7\text{F}_1$  that are not affected by local symmetry in both two crystals we

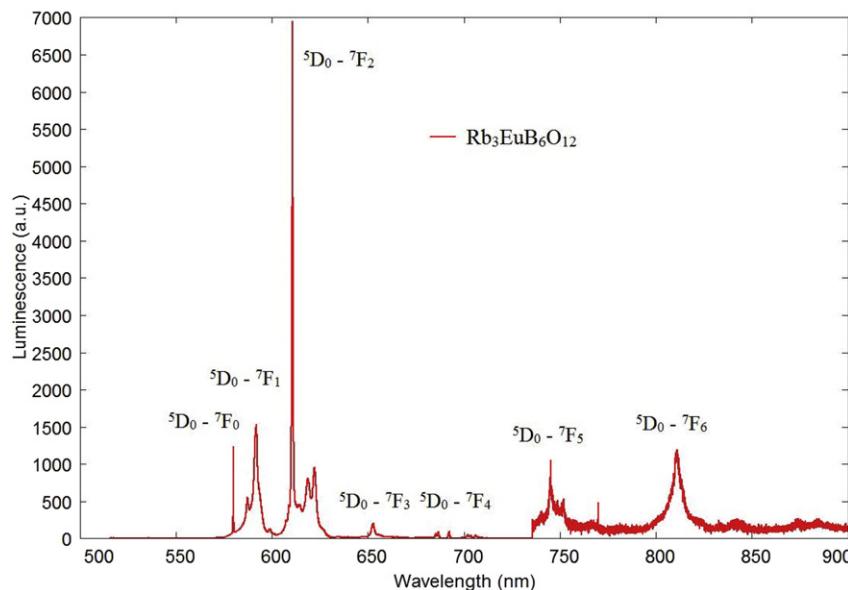

can deduce that radiativeless losses in  $\text{Rb}_3\text{EuB}_6\text{O}_{12}$  are more than order of magnitude higher than in  $\text{Eu}_2(\text{MoO}_4)_3$ .

Another interesting feature of borate  $\text{Rb}_3\text{EuB}_6\text{O}_{12}$  is the shape of hypersensitive  $^5\text{D}_0 - ^7\text{F}_2$  transition band which is dominated by a single narrow peak at 611 nm, as shown in Fig. 9. This feature is, in principle, favorable for obtaining the lasing at this transition since the amplification cross section is not smeared over a wide spectral region, but it is concentrated in the peaking wavelength vicinity (Fig. 3S). However, due to the above-described fact that the concentration quenching in  $\text{Rb}_3\text{EuB}_6\text{O}_{12}$  is stronger than in  $\alpha\text{-Eu}_2(\text{MoO}_4)_3$ , the use of a lower Eu content must be recommended, e.g. by diluting  $\text{Eu}^{3+}$  with  $\text{Gd}^{3+}$  which possesses the closest ionic radius.

Naturally, the properties of bulk crystals of  $\text{Rb}_3\text{EuB}_6\text{O}_{12}$  may differ from those of microcrystals studied in our paper. Difference between luminescent properties of polycrystalline and single crystalline samples may be due a) size effects (quantum confinement, surface-versus-bulk etc) b) poorer crystalline quality of the former c) anisotropy effects. According to electron microscopy, individual crystallite size is of order 1  $\mu\text{m}$  that rules out size effects. Quality of XRD patterns admits the absence of crystal structure defects. Therefore, from the first two points, there are no reasons to expect the difference between poly- and single crystalline samples. However, anisotropy effects are expected in view of uniaxial symmetry of the crystal, and they must be investigated separately after the single crystals will be grown.

#### 4. Conclusions

In the  $\text{K}_3\text{YB}_6\text{O}_{12}$  borate family, new NCS Rb-containing borates  $\text{Rb}_3\text{REB}_6\text{O}_{12}$  ( $\text{RE} = \text{Nd}, \text{Eu}$ ) were discovered and this greatly extends the nomenclature of the NCS borate crystals available in this family. As it is clear, this borate family covers a wide range of RE elements, including those appropriate for laser and photonic applications. Thus, a more wide design and deep investigation of the compounds related to the  $\text{M}_3\text{REB}_6\text{O}_{12}$  ( $\text{M} = \text{alkaline metals}; \text{RE} = \text{Y, rare earth metals}$ ) crystal family is topical, including a search for new compounds and solid solutions, development of the crystal growth methods, the observation of piezoelectric and luminescence characteristics. This opens a door for the estimation of this borate family potential for practical applications. The luminescence properties of  $\text{Eu}^{3+}$  ions, along with nonlinear properties of the matrix, indicate that Eu-activated crystals of the  $\text{Rb}_3\text{REB}_6\text{O}_{12}$  family ( $\text{RE} = \text{Gd, La and probably Y and Lu}$ ) can be designed and they are good candidates for self-doubling Eu-lasing media.

**Fig. 9.** High-resolution PL spectrum for  $\text{Rb}_3\text{EuB}_6\text{O}_{12}$  recorded at excitation 514.5 nm with a T64000 spectrometer. The long-wavelength part is multiplied by 400 and shifted up.

## Acknowledgements

We are grateful to Guochun Zhang for the crystal structure materials on  $K_3YB_6O_{12}$  and O. Tsydenova, A. Sarapulova for the consultations. The work was supported by Projects № 0356-2015-0412 of SB RAS Program № II.2P and № 0339-2016-0007. The reported study was funded by RFBR according to research projects 16-52-48010, 17-02-00920, 17-03-00886 and 17-52-53031 and RSF project 14-22-00143. The work was supported by Act 211 Government of the Russian Federation, contract № 02.A03.21.0011, and by the Ministry of Education and Science of the Russian Federation (5.5523.2017/8.9). This research was supported by Grant no. 8.2.01.2017 of Tomsk State University Academic D.I. Mendeleev Fund Program.
