Judd–Ofelt parameters

### ABSTRACT

Polarized absorption spectra of ferroborates  $\text{HoFe}_3(\text{BO}_3)_4$ ,  $\text{NdFe}_3(\text{BO}_3)_4$  and  $\text{Ho}_{0.75}\text{Nd}_{0.25}\text{Fe}_3(\text{BO}_3)_4$  were measured at room temperature in spectral range  $4000\text{--}24500\text{ cm}^{-1}$  ( $400\text{--}2500\text{ nm}$ ). The studied single crystals were grown from solution-melts. Intensities of the  $f\text{-}f$  transitions were measured and the Judd–Ofelt parameters  $\Omega_\lambda$  of  $\text{Ho}^{3+}$  and  $\text{Nd}^{3+}$  ions in the studied crystals were calculated. It was revealed that the crystals content not strongly influences the Judd–Ofelt parameters. The  $\Omega_2$  parameter for  $\text{Ho}^{3+}$  ion is the most sensitive to the crystal content. Linear dichroism of the hypersensitive transitions appeared to be the largest one for both rare earth ions.

### 1. Introduction

Borates  $\text{RM}_3(\text{BO}_3)_4$  (R=Y or rare earth (RE) element, M=Al, Ga, Cr, Fe, Sc) have huntite-like structure. RE ferroborates  $\text{RFe}_3(\text{BO}_3)_4$  attract great interest of researchers, because, in a number of cases, such crystals belong to the class of multiferroics [1–3]. Multiferroics are the materials which possess the interrelated magnetic, electric and elastic ordering. Spectroscopic properties of Ho and Nd ions in various compounds were investigated for a long time and extensively (in the network of the Judd–Ofelt theory including) [4–15], however the Judd–Ofelt spectroscopic parameters  $\Omega_\lambda$  of RE ions in  $\text{HoFe}_3(\text{BO}_3)_4$ ,  $\text{NdFe}_3(\text{BO}_3)_4$  and  $\text{Ho}_{0.75}\text{Nd}_{0.25}\text{Fe}_3(\text{BO}_3)_4$  single crystals were not determined earlier. Fine structure of  $f\text{-}f$  transitions was investigated in  $\text{HoFe}_3(\text{BO}_3)_4$  [16] and in  $\text{NdFe}_3(\text{BO}_3)_4$  crystals [17] in the visible and near infrared spectral range. Intensities of  $f\text{-}f$  transitions strongly depend on the symmetry of compound, on the local environment of the RE ion, in particular. The precise theoretical prediction of  $f\text{-}f$  transitions intensities of the RE ion in the specific compound is not possible at the moment. Therefore, the aim of this work was investigation of optical properties of the mentioned ferroborates and search of correlation between obtained results and structure of the crystals.

Structure of the studied crystals belongs to trigonal symmetry class. Trivalent RE ions occupy positions of only one type. They are located at the center of trigonal prisms made up of six crystallographically equivalent oxygen ions. The triangles formed by the oxygen ions in the neighboring basal planes are not superimposed on each other but are twisted by a certain angle. Owing to this distortion, the symmetry  $D_{3h}$  of the ideal prism is reduced to the symmetry  $D_3$  [18]. According to the

literature data,  $\text{HoFe}_3(\text{BO}_3)_4$  crystal, as many of the ferroborates, undergoes the structural phase transition from  $R32$  to  $P3_121$  symmetry. At this transition the local symmetry of RE ion decreases from  $D_3$  to  $C_2$  one. The temperature of the transition depends strongly on the method of crystal growing: it amounts 427 K for the powder samples obtained by the solid-state synthesis [19] and 360 K for the single crystals grown from a solution-melt [20]. At room temperature  $\text{HoFe}_3(\text{BO}_3)_4$  crystal has  $P3_121$  symmetry. In  $\text{Ho}_{0.75}\text{Nd}_{0.25}\text{Fe}_3(\text{BO}_3)_4$  crystal the structural phase transition happens at 200 K [21]. Thus, at room temperature symmetry of this crystal is  $R32$ . Symmetry  $R32$  of  $\text{NdFe}_3(\text{BO}_3)_4$  crystal does not change with the decrease of temperature till 1.6 K [22].

### 2. Experimental details

Single crystals were grown from a bismuth trimolybdate solution-melts with a nonstoichiometric ratio of the crystal constitutive oxides of  $(100 - n)$  mass %  $[\text{Bi}_2\text{Mo}_3\text{O}_{12} + p\text{B}_2\text{O}_3 + q(1-x)\text{Ho}_2\text{O}_3 + qx\text{Nd}_2\text{O}_3] + n$  mass %  $\text{Ho}_{1-x}\text{Nd}_x\text{Fe}_3(\text{BO}_3)_4$  ( $x = 0; 0.25; 1$ ) [23]. Values of parameters  $n$ ,  $p$ ,  $q$  and saturation temperature  $T_{\text{sat}}$  see in Table 1. In these solution-melts the trigonal huntite is the high temperature phase and only this phase crystallizes above  $T \approx 900^\circ\text{C}$ . The solution-melts with a mass of 100 g were prepared in platinum crucibles. They were kept during 8–10 hours at  $T = 1100^\circ\text{C}$  with permanent mixing by a reversibly rotating platinum rod for homogenization. When the temperature was lowered to  $T = T_{\text{sat}} - (5\text{--}7)^\circ\text{C}$ , the rod was lifted over the solution-melt. At the same time the spontaneous crystallization takes place into the thin overcooled layer of the solution-melt which stays on the rod. The rod was again immersed into the solution-melt. Then the temperature

**Table 1**  
Crystallization parameters.

Crystal composition	<i>n</i>	<i>p</i>	<i>q</i>	<i>T</i> <sub>sat</sub> (°C)
HoFe <sub>3</sub> (BO <sub>3</sub> ) <sub>4</sub>	25	3	0.5	960
NdFe <sub>3</sub> (BO <sub>3</sub> ) <sub>4</sub>	23.3	3.14	0.54	945
Ho <sub>0.75</sub> Nd <sub>0.25</sub> Fe <sub>3</sub> (BO <sub>3</sub> ) <sub>4</sub>	24.5	3	0.6	970

was lowered by (1–3) °C/24 h. The crystallization process was stopped at *T* = 930–945 °C. Crystal compositions have been given in accordance with calculation of solution-melts. Crystals with linear dimensions up to 7 mm were grown. For the optical measurements the samples were prepared as the polished plates about 0.2 mm thick, with the *C*<sub>3</sub> axis parallel to the plate surface.

The absorption spectra were measured by the two beam technique, using an automated spectrophotometer designed on the basis of the diffraction monochromator MDR-2. In the spectral range 400–500 and 1000–2500 nm the measurements were carried out on a spectrophotometer SHIMADZU UV-3600. The absorption spectra were obtained with the light propagating normally to the *C*<sub>3</sub> axis of the crystal for the light electric vector  $\vec{E}$  parallel ( $\pi$  spectrum) and perpendicular ( $\sigma$  spectrum) to the *C*<sub>3</sub> axis of the crystal. Optical slit width (spectral resolution) was 0.2 nm in the region of 400–600 nm and 0.4 nm in the region of 600–2500 nm.

### 3. Results and discussion

Absorption spectra (decimal absorption coefficient) of HoFe<sub>3</sub>(BO<sub>3</sub>)<sub>4</sub>, NdFe<sub>3</sub>(BO<sub>3</sub>)<sub>4</sub> and Ho<sub>0.75</sub>Nd<sub>0.25</sub>Fe<sub>3</sub>(BO<sub>3</sub>)<sub>4</sub> single crystals for  $\pi$  and  $\sigma$  polarizations at room temperature in the range from 10000 to 24500 cm<sup>-1</sup> are presented in Figs. 1–4. Observed spectra consist of sets of narrow lines connected with the *ff* transitions in Ho<sup>3+</sup> and Nd<sup>3+</sup> ions and of wide bands due to *d-d* transitions in Fe<sup>3+</sup> ions. At *E* ~ 11500, 16000 and 22750 cm<sup>-1</sup> the transitions <sup>6</sup>A<sub>1</sub> → <sup>4</sup>T<sub>1</sub>, <sup>4</sup>T<sub>2</sub>, <sup>4</sup>A<sub>1</sub> → <sup>4</sup>E (in cubic crystal field notation) in Fe<sup>3+</sup> ions are observed (Figs. 1–4), and at *E* > 25000 cm<sup>-1</sup> the edge of the strong absorption occurs [24]. Absorption, caused by Fe<sup>3+</sup> ions, were approximated by Gaussian curves and subtracted from the full spectra. As a result we received absorption spectra only of *ff* transitions in RE ions. In Fig. 5 the *ff* transitions of Ho<sup>3+</sup> ions in HoFe<sub>3</sub>(BO<sub>3</sub>)<sub>4</sub> and Ho<sub>0.75</sub>Nd<sub>0.25</sub>Fe<sub>3</sub>(BO<sub>3</sub>)<sub>4</sub> crystals in spectral range 4000–10000 cm<sup>-1</sup> are presented. Identification of *ff* absorption lines was carried out on the basis of Carnall [25] and Kaminskii [26].

Intensities of *ff* absorption lines in  $\pi$  and  $\sigma$  polarizations ( $I_{\pi}$  and  $I_{\sigma}$ )

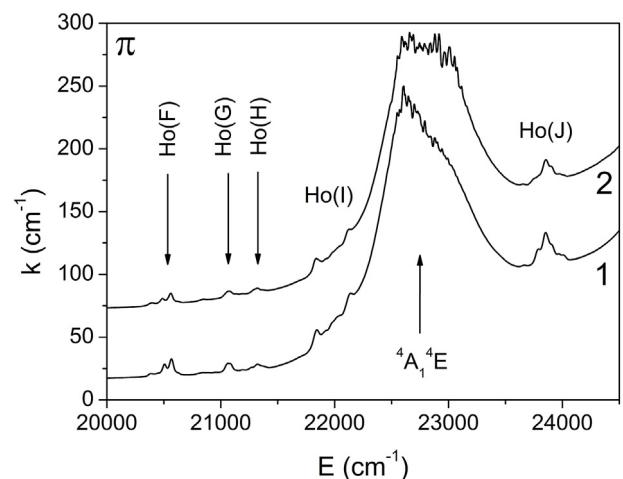

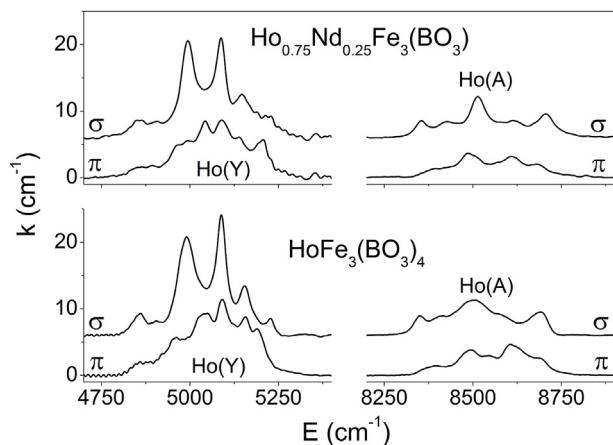

Fig. 4. Absorption spectra in  $\pi$ -polarization of the HoFe<sub>3</sub>(BO<sub>3</sub>)<sub>4</sub> (1) and Ho<sub>0.75</sub>Nd<sub>0.25</sub>Fe<sub>3</sub>(BO<sub>3</sub>)<sub>4</sub> (2) single crystals at room temperature.

were determined from the spectra as integrals  $I = \int \frac{k(E)}{C_{RE}} dE$ , where  $C_{RE}$  is the molar concentration of the corresponding RE ion in the crystal in units of mol/l,  $E$  is the energy in cm<sup>-1</sup>. Concentration of RE ions ( $C_{RE}$ )

**Fig. 5.**  $\sigma$  and  $\pi$  absorption spectra of the  $f-f$  transitions of  $\text{Ho}^{3+}$  ions in  $\text{HoFe}_3(\text{BO}_3)_4$  and  $\text{Ho}_{0.75}\text{Nd}_{0.25}\text{Fe}_3(\text{BO}_3)_4$  crystals.

in the  $\text{HoFe}_3(\text{BO}_3)_4$  and  $\text{NdFe}_3(\text{BO}_3)_4$  crystals was accepted to be identical and equal to 8.34 mol/l. For the  $\text{Ho}_{0.75}\text{Nd}_{0.25}\text{Fe}_3(\text{BO}_3)_4$  crystal the values  $C_{RE}$  were calculated according to the chemical formula of the compound and were equal to  $C_{\text{Ho}} = 6.255 \text{ mol/l}$  and  $C_{\text{Nd}} = 2.085 \text{ mol/l}$ . Experimentally obtained intensities of  $f-f$  transitions in  $\pi$  and  $\sigma$  polarizations ( $I_\pi$  and  $I_\sigma$ ) are presented in [Tables 2 and 3](#). The transition intensities were averaged over the polarizations according to the common relation for uniaxial anisotropic crystals:  $I_{IF} = (2I_\sigma + I_\pi)/3$ . Following to the Ref. [27], we calculated oscillator strengths of transitions  $I \rightarrow F$  between  $J$  multiplets by the equation:

$$f_{IF} = 4.318 \cdot 10^{-9} \frac{3n}{(n^2 + 2)} I_{IF}. \quad (1)$$

There are no experimental data about refractive index  $n$  of the studied crystals up to date. Refractive index of ferroborates slightly depends on rare earth ion. Earlier [28] we measured refractive index for  $\text{ErFe}_3(\text{BO}_3)_4$  single crystal:  $n \approx 2$ , and we used this value in the present work. Experimentally determined oscillator strengths  $f_{IF}$  are presented in [Tables 4 and 5](#).

The transition strength is defined as:  $s_{IF} = \frac{1}{e^2} \sum_{if} |\vec{D}_{if}|^2$ , where  $i \in I$ ,  $f \in F$  and  $\vec{D}_{if}$  – the matrix element of the electric dipole moment. The transition strength and the oscillator strength are related by the expression [29]:

$$s_{IF} = \frac{3hg_I}{8\pi^2 m c k_{IF}} f_{IF}, \quad (2)$$

where  $g_i$  is the degree of degeneracy of the initial state and  $k_{IF}$  is the

average wave number of the absorption band. Experimentally obtained  $k_{IF}$  of the studied  $f-f$  transitions are given in [Tables 2 and 3](#).

In the network of the Judd–Ofelt theory, the strength of an  $f-f$  transition in RE ion in the non-centrosymmetrical crystal field is described by the relationship [30–32]:

$$s_{IF} = \sum_{\lambda} \Omega_{\lambda} \Gamma_{\lambda}^2(I, F). \quad (3)$$

Coefficients  $\Gamma_{\lambda}^2(I, F) = \langle I \| U^{(\lambda)} \| F \rangle^2$  are calculated theoretically and are considered to be independent of the crystal structure. For the calculations we used coefficients  $\Gamma_{\lambda}^2(I, F)$  from the works of Carnall [25] for  $\text{Ho}^{3+}$  ion and of Kaminskii [26] for  $\text{Nd}^{3+}$  ion ([Tables 4 and 5](#)). The index  $\lambda$  for  $f-f$  transitions takes three values: 2, 4, and 6. It is possible to find three parameters  $\Omega_{\lambda}$  from the experimentally obtained strengths of the viewed transitions in the RE ion and to calculate the strengths of all other possible  $f-f$  transitions. The transitions under consideration are forbidden in the free RE ion in the electric dipole approximation not only by the parity, but some of them are forbidden by the total momentum in accordance with the selection rule  $\Delta J = 0, \pm 1$ . According to the Judd–Ofelt theory [32], when transitions are allowed by the parity selection rule due to the odd components of the crystal field, they can occur at  $\Delta J \leq \lambda$  ( $\lambda = 2, 4$  and 6, as mentioned above). Among all studied transitions ([Tables 2 and 3](#)) only one transition does not satisfy this condition:  ${}^5I_8 \rightarrow {}^5F_1$  (Band I) in  $\text{Ho}^{3+}$  ions ([Table 2](#)). Correspondingly, all parameters  $\Gamma_{\lambda}^2 = 0$  for this transition [25,26] ([Table 4](#)), and it is possible to assume that intensity of this transition is indistinguishably small and its contribution to the intensity of the band I is insignificant although this transition coincides by energy with transition  ${}^5I_8 \rightarrow {}^5G_6$ .

Equation (3) can be written in the vector form:

$$\vec{s} = A \vec{\Omega}. \quad (4)$$

Here  $\vec{s}$  is the  $q$ -dimensional vector consisting of the measured strengths of the transition groups;  $q$  is the number of the considered groups of transitions;  $\vec{\Omega}$  is the three-dimensional vector of parameters  $\Omega_{\lambda}$  ( $\lambda = 2, 4, 6$ );  $A$  is the  $3 \times q$ -dimensional matrix of the coefficients  $\Gamma_{\lambda}^2(I, F)$ . The vector  $\vec{\Omega}$  that minimizes the sum of the squares of the deviations between the measured and theoretical transition strengths is given by the matrix equation [33]

$$\vec{\Omega} = (A^T A)^{-1} A^T \vec{s}, \quad (5)$$

where  $A^T$  is the transposed matrix. Thus we received the set of parameters  $\Omega_{\lambda}$ .

For calculation of the  $\Omega_{\lambda}$  parameters we used  $f-f$  bands Y, A, B, D, E, F, G, H, I, J in  $\text{Ho}^{3+}$  ions ([Tables 2 and 4](#)) and R, S, A, B, C, D, E, F bands in  $\text{Nd}^{3+}$  ions ([Tables 3 and 5](#)). On the basis of the received parameters

$\Omega_\lambda$ , the strengths of the transitions were calculated from Eq. (3) (Tables 4 and 5). Correlation between the experimentally obtained and calculated strengths of the transitions estimates the precision of the results. The relative root mean square error of the theoretical description of the transition strengths is defined by equation:

$$\delta = \left[ \frac{q \sum \Delta s^2}{(q - p) \sum s^2} \right]^{1/2}. \quad (6)$$

Here  $s$  are the measured transition strengths,  $\Delta s$  are the differences between the measured and calculated transition strengths (see Tables 4 and 5),  $p$  is the number of the determined parameters, being equal to 3 in our case.

As a result, we determined parameters  $\Omega_\lambda$  for the  $\text{Ho}^{3+}$  and  $\text{Nd}^{3+}$  ions in the studied crystals with accuracy  $\delta$  about 7% and 12% respectively. The received Judd-Ofelt parameters and their comparison with the literature data for other compounds containing the studied RE ions are presented in Tables 6 and 7. It should be noted that parameter  $\Omega_4$  of the  $\text{Nd}^{3+}$  ions (see Table 7, lines 1–3) considerably decreases with the decrease of concentration of the ions in the investigated ferroborate crystals. The set of the studied transitions and of their  $\Gamma_\lambda^2(I, F)$  coefficients for the  $\text{Ho}^{3+}$  ion (Table 4) shows that parameter  $\Omega_2$  (Table 6) is almost completely defined by intensity of the I-band.

Transitions I ( $^5I_8 \rightarrow ^5G_6$ ) in  $\text{Ho}^{3+}$  ions and D ( $^4I_{9/2} \rightarrow ^4G_{5/2}$ ) in  $\text{Nd}^{3+}$  ions were referred to the hypersensitive ones in Ref. [32]. The hypersensitive transitions are usually characterized by the large intensity which strongly depends on the local environment. The mentioned transitions reveal the hypersensitive properties also in our crystals (Tables 4 and 5). These transitions are also characterized by the large

value of the  $\Gamma_2^2$  coefficient relative to other transitions (Tables 4 and 5). This means that 1-st and 3-d spherical harmonics  $t$  ( $t = \lambda \pm 1$  [32]) in the expansion of the crystal field take part in the allowance of the mentioned transitions by parity, while only higher harmonics are active in the allowance of the rest of the transitions.

We can contend that the concentrations of  $\text{Ho}^{3+}$  and  $\text{Nd}^{3+}$  ions in the mixed crystal  $\text{Ho}_{0.75}\text{Nd}_{0.25}\text{Fe}_3(\text{BO}_3)_4$  correspond to the declared composition. It follows from the fact that intensities of  $f-f$  transitions normalized by concentration of rare-earth ions not strongly differ in mixed and pure crystals (see, for example, oscillator strengths  $f_{IF}$  in Tables 4 and 5, or integrated intensities  $I_\pi, I_\sigma$  in Tables 2 and 3). At the same time, hypersensitive transitions (I for  $\text{Ho}^{3+}$  and D for  $\text{Nd}^{3+}$  ions) should not be taken into account because their intensity is very sensitive to changes of the local environment.

In all studied crystals we observe the difference of  $f-f$  spectra measured in the  $\pi$  and  $\sigma$  polarizations, i.e. linear dichroism. The measure of the dichroism is the ratio of intensities of bands in  $\sigma$  and  $\pi$  polarizations -  $I_\sigma/I_\pi$ . For all studied transitions these values were calculated and presented in Tables 2 and 3. It should be noted that the dichroism of the hypersensitive transitions is much larger than dichroism of other measured transitions. In particular, value of the dichroism of the I-band of the  $\text{Ho}^{3+}$  ions (Table 2) in both crystals is about 10, whereas the dichroism of other transitions does not exceed value 3.5. The total dichroism  $\Sigma I_\sigma/\Sigma I_\pi$  (Table 2) of all studied  $f-f$  bands in the  $\text{Ho}^{3+}$  spectra (with the exception of I-band) is 1.56 for the  $\text{HoFe}_3(\text{BO}_3)_4$  crystal and 1.81 for the  $\text{Ho}_{0.75}\text{Nd}_{0.25}\text{Fe}_3(\text{BO}_3)_4$ . Difference of these values can be explained by the difference of parameters of the local environment of the  $\text{Ho}^{3+}$  ions in the studied crystals.

For the  $\text{Nd}^{3+}$  ions (Table 3) the dichroism of hypersensitive transition D:  $I_o/I_\pi \sim 4$  also noticeably exceeds the dichroism of other studied transitions. The total dichroism (Table 3) of all studied f-f bands of the  $\text{Nd}^{3+}$  ions (with the exception of D-band) is 1.72 for the  $\text{NdFe}_3(\text{BO}_3)_4$  and 1.75 for the  $\text{Ho}_{0.75}\text{Nd}_{0.25}\text{Fe}_3(\text{BO}_3)_4$  crystals. The total dichroism of the same set of transitions in  $\text{Nd}^{3+}$  ions in the  $\text{Nd}_{0.5}\text{Gd}_{0.5}\text{Fe}_3(\text{BO}_3)_4$  crystal was equal to 1.71 [11]. Values of the total dichroism ( $\Sigma I_o/\Sigma I_\pi$ ) are practically identical for the above mentioned three crystals with identical symmetry R32 at room temperature and it is possible to conclude that parameters of the local environment of

$\text{Nd}^{3+}$  ions in these crystals are similar, in spite of the large difference of the  $\text{Nd}^{3+}$  ions concentrations in these crystals.

#### 4. Summary

Absorption spectra of single crystals  $\text{HoFe}_3(\text{BO}_3)_4$ ,  $\text{NdFe}_3(\text{BO}_3)_4$  and  $\text{Ho}_{0.75}\text{Nd}_{0.25}\text{Fe}_3(\text{BO}_3)_4$  for  $\pi$ - and  $\sigma$ -polarizations were measured at room temperature in spectral range from 4000 to 24500  $\text{cm}^{-1}$  (400–2500 nm). The crystals were grown from a solution-melt. The d-d absorption of the  $\text{Fe}^{3+}$  ions and f-f transitions of  $\text{Ho}^{3+}$  and  $\text{Nd}^{3+}$  ions in the spectra were separated. The f-f spectra of the rare earth ions were analyzed in the network of the Judd–Ofelt theory. Intensities of the f-f transitions were measured and the Judd–Ofelt parameters  $\Omega_\lambda$  of  $\text{Ho}^{3+}$  and  $\text{Nd}^{3+}$  ions in the studied crystals were calculated. It was revealed that the crystals content not strongly influences the Judd–Ofelt parameters. The  $\Omega_2$  parameter for  $\text{Ho}^{3+}$  ion is the most sensitive to the crystal content. Linear dichroism of the hypersensitive transitions is the largest one for both rare earth ions, especially for holmium. The total dichroism of f-f transitions is independent of the concentration of  $\text{Nd}^{3+}$  ions in the studied crystals which has identical symmetry. For the  $\text{Ho}^{3+}$  containing crystals the total dichroism depends on the crystal symmetry.
